KEITH & FLACK, plumbers and steam fitters, Shelbyville, Ind., report that they have had a successful year and are now going into larger and better quarters, and expect to do well in 1894.

T. W. CULLEN, who has been engaged in the stove and plumbing business on Felton street, Waltham, Mass., for 15 years, has removed to the new Buckley Block, Moody street.

COL. W. T. MCGURRIN of the plumbing house of Sproul & McGurrin, Grand Rapids, Mich., acted as toastmaster at the Grand Rapids plumbers' convention. Robert Sproul of the same house, in a humorous speech, stated that he had frequently removed quantities of diamonds from waste pipes that were reported to be stopped and in every case returned them to the owner.

JAMES SULLIVAN, Newton Centre, Mass., intends to open a plumbing establishment

W. R. WILDER, bookkeeper for Parsons & Sears, and James Collins, a plumber employed by that firm, have leased the Fenn street store vacated by H. W. Partridge and will start a new plumbing establishment at Pittsfield, Mass.

THE FIRM of Dunwoody & Collins, plumbers, Waterford, N. Y., have dissolved by mutual consent. Mr. Collins will continue the business.

WILLIAM H. ASH has begun the erection of two three-story frame buildings at the corner of Briggs and Atlantic avenues, Clarenceville, N. Y. They

will have stores on the first floor and living apartments overhead. Mr. Ash will occupy one of the stores for his plumbing business.

GEORGE H. MCCALMON & SON, plumbers, have opened a shop in the rear of 212 Main street, Biddeford, Maine.

DAVID W. YARBOROUGH is reported to have bought the entire stock of Stockton & Kuhrt at Atlanta, Ga., and moved it to his establishment at 18 East Hunter street.

ONE OF THE ECHOES of the Grand Rapids, Mich., plumbers' convention in reference to bad plumbing was that "real estate sharks, who wish to realize 50 per cent. upon their investments, cut their plumbing bills down by putting in inferior work, to the great detriment of the occupants."

PLANS AND SPECIFICATIONS have been prepared for the enlargement of the S. H. Beard Heating & Plumbing Company's building, on Arch street, New Britain, Conn.

EDSON L. CLARK has opened a plumbing establishment at 77 Second street, Newburg, N. Y.

THE SYSTEM of Instructor Walmsley with the lead burning class at the New York Trade School has been so successful that an effort is being made by some who did not take this course to have him take another class at the close of the school. The instructor is highly gratified with the work of the young plumbers, who can show some masterpieces of workmanship.

PRICE BROS., Macomb, Ill., will move their plumbing and electric fixture establishment to Oakman & Clugsten's furniture store, where they will occupy a portion of the building.

THE A. Y. MCDONALD COMPANY, 168 Lake street, Chicago, have arranged with the Henry Huber Company of New York to handle all the plumbing specialties manufactured by the latter company, exclusively in the States of Michigan, Indiana, Illinois and Wisconsin and all territory west of the Mississippi River. The Henry Huber Company will discontinue their supply house at 231 East Kinzie street, and all of their goods will be carried by the A. Y. McDonald Company, who are to make extensive alterations in their store, including the fitting up of an elegant showroom.

THROUGH the courtesy of Secretary James T. McNab of the Master Plumbers' Association of Passaic County, N. J., we receive the following list of officers elected at a recent meeting at Paterson, N. J.: President, John Hickman; vice president, John Quinn; treasurer, E. W. Blair; secretary, James T. McNab; sergeant-at-arms, T. J. Brogan. Trustees: M. Nealon, Chas. Walls and Thomas Wilson.

THE VALUE of tight plumbing fixtures in houses when a drought affects the source of a water supply was shown in a very plain way at Northampton, Mass., last summer, says the superintendent of the water works. The city has a gravity supply which has been adequate for its needs until the summer of 1893, when the greatly diminished rainfall and increased consumption of water combined to reduce the storage to a dangerously small quantity. The superintendent investigated the matter and found that the city was using and wasting more water than others similarly situated, so a house to house inspection of the fixtures was made and leaks were stopped. He states that this resulted in reducing the consumption possibly one-half and increasing the pressure about 20 pounds at the hydrants.

THE STORE at 78 Union street, Portland, Maine, recently vacated by J. M. Fox, electrician, is now occupied by Myers & Mahoney, practical plumbers, who are prepared to do all kinds of work in their line. They make a specialty of bending brass piping.

WELLS BROTHERS & COMPANY, Greenfield, Mass., make a specialty of stay bolt taps. They make any size desired and keep in stock a large variety of sizes and lengths made in the following proportions: one-third reamer, one-sixth taper, one sixth thread and one-third shank.

FINDEISEN & KROPF succeed Durfee & Findeisen, manufacturers of plumbers' wood work supplies, 132–134 West Lake street, Chicago. J. A. Durfee retires, his place in the company being taken by O. F. Kropf.

THE CITY OF ROME, GA., is remodeling and adding to its ordinances for local government. Among the additions is a plumbing ordinance, which is said to go into minute details and provide a better sanitation. An ordinance in drainage and sewerage is being elaborated to provide for a better system for the disposal of waste.

CHARLES H. DELOID, who up to the time of closing of the establishment of Davis & Co. was foreman in their plumbing department, has opened a plumbing establishment at 1 Water street, Gloucester, Mass.

PECK BROTHERS & CO., 259 Wabash avenue, Chicago, are getting out their new closet repair coupling, and at present are unable to supply the demand. The plumbers speak very highly of the device.

New York State Master Plumbers.

The sixth annual convention of the Master Plumbers' Association of the State of New York was called to order on March 6, at Buffalo, N. Y., by President Chas. Geiger, at the Builders' Exchange, a large number of delegates being present. After a short speech he introduced the Mayor, who addressed the convention and extended to them the freedom of the city. James S. Stygall, president of the Buffalo Association of Master Plumbers, reiterated the welcome, as chairman on entertainment. National President Daniel G. Finnerty then made a speech, in which he pointed out that one of the main duties of the association was to educate those in the trade who were not qualified to do good work, and he urged the bringing in of all master plumbers, so that all could receive the advantages of association. Mr. Finnerty referred in touching terms to the recent death of a member of the Executive Committee of the National Association, James G. Welden of Pittsburgh, and later resolutions of condolence were passed and ordered to be sent to the bereaved family.

John Mitchell of New York, vice-president of the National Association, also spoke, dwelling upon the high aims that should be pursued by the master plumbers. He urged the securing of laws that would bring about the best kind of inspection of plumbing work—inspection by skilled plumbers—and he urged the securing of laws that would punish plumbers for doing improper work.

A Credential Committee was appointed, who in their report showed a membership of 768, an increase of 45 since the last convention. Representatives from the Journeymen's Union were received, who asked for action to reduce the number of apprentices, and after some discussion on the subject it was referred to the Committee on Laws and Legislation. The Sanitary Committee reported that great progress had been made in sanitation, and that the advance still continued. The Committee on Legislation reported that several objectionable measures had been shelved in the Legislature through their efforts, and that some equally unwise were now pending that would be carefully watched. The treasurer's report showed the association in good financial condition, and recommendations to strengthen it were discussed and favorable action taken. On the third day of the convention the annual election was held, Mr. Geiger declining re-election. The following officers were elected:

President, William J. McDermott, New York.

Vice-president, Henry E. Weiber, Kingston.

Recording secretary, Charles Schloesser, New York.

Financial secretary, Horace F. Westcott, Albany.

Treasurer, William Reid, Rochester.

Delegates at-large to State Convention, Messrs. Callahan of Jamestown; Barnes of Troy, Collins of New York. Delegates-at-large to National Convention: J. A. Rossman of New York and Charles Geiger of Buffalo.

The constitution was amended to a slight extent and Troy was selected as the next convention city. During the convention theater parties, drives, a reception by the Knights of Tobasco, and a banquet, at which James S. Stygall acted as toastmaster, gave the visitors a lasting impression of Buffalo hospitality.

"Knights of Tobasco."

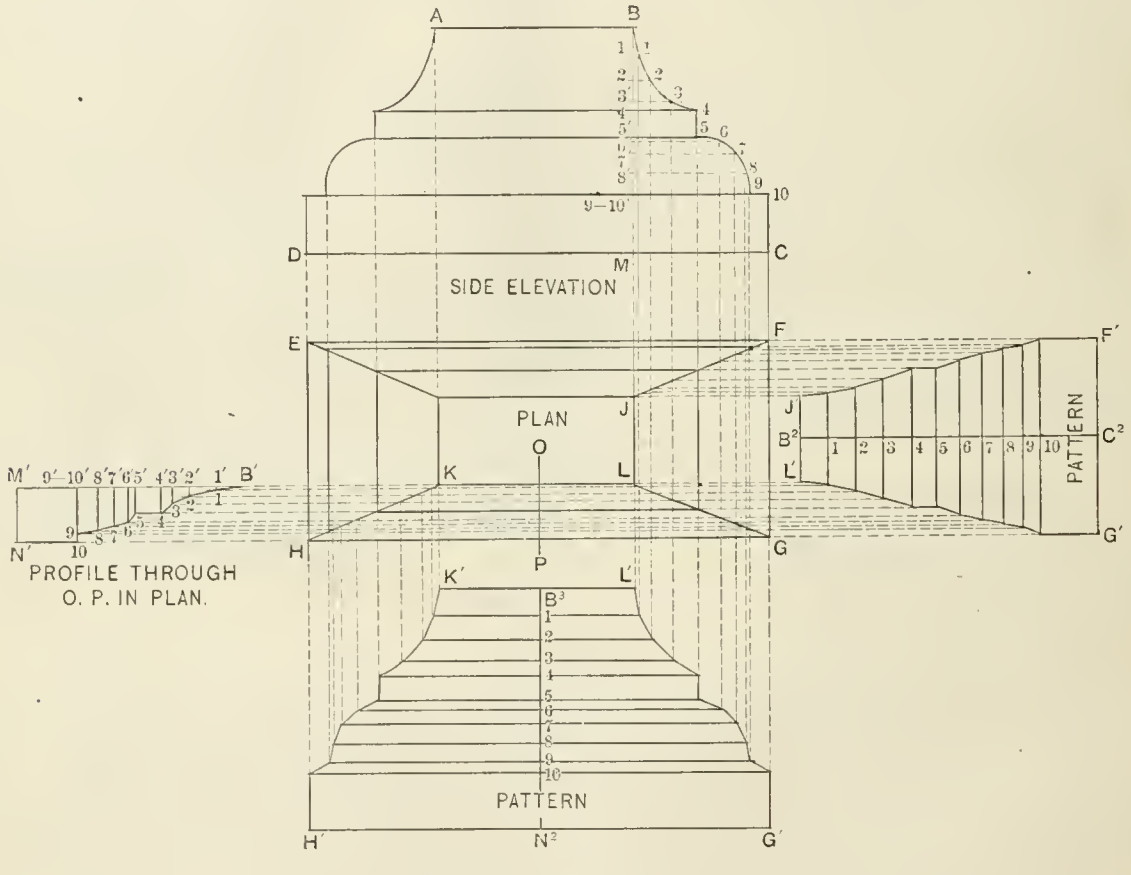
While the convention of master plumbers was in session at Buffalo the Knights of Tobasco became a permanent institution, holding two sessions and adopting a constitution. The officers are curiously styled as follows: President to be called "Old Pepper;" vice-president, "Young Pepper;" secretary, "Black and White Pepper;" treasurer, "Red Pepper;" directors, "Mixed Peppers." "Tobasco" means "hot stuff," and the name was suggested by the "father" of the order, genial Tom Cushing of New York. The Knights have adopted two series of yells, and if you can't see the Knights you can hear them. The yells are "T-o-b a s-c o. Hot stuff. Hot stuff. Oh! oh, oh," and "Who are we? Who are We? Knights of Tobasco, can't you see?' About 75 delegates were in attendance. The membership is restricted to traveling men connected with the plumbing, steam, gas and water fitting trades. It was resolved to meet in Troy next year, at the same time the master plumbers meet. The election of officers resulted as follows: Old Pepper, Thomas F. Cushing, New York; Young Pepper, D. M. Davidson, New York; Black and White Pepper, Louis W. Gay, Buffalo; Red Pepper, Robert T. Eddy, Buffalo; Board of Mixed Peppers, Charles S. Siddons, Buffalo; D. L. Hamill, Albany; Philip Becker, Syracuse; John J. Cary, Baltimore; Frank J Rourke, New York.

ROOFING AND CORNICE.

Pattern for Molded Base.

From P. S., *Moberly, Mo.*—Please publish in *The Metal Worker* pattern for a rectangular molded base, the molding of the sides being similar to that of the ends, but having less projection.

Answer.—Let A B C D in the cut represent the side view of the base and E F G H the plan. B C and A D show the profile of the ends of the base. As the projection through the sides of the base is less than that of the ends, a profile must be obtained through the side O P in plan, from which to obtain the stretchout in producing the pattern of sides. To obtain the pattern for the end proceed as follows: Divide the profile B C into an equal number of parts, as shown by the small figures, and from the points obtained drop lines at right angles to A B until they intersect the miter lines J F and L G in plan. At right angles to F G draw the line B^2 C^2, upon which place the stretchout of the profile B C, as shown by the small figure, through which draw the usual measuring lines, which intersect with lines of corresponding numbers drawn from the miter lines at right angles to F G. A line traced through these intersections, as shown by J′ L′ G′ F′, will be the required pattern for the end of the base. To obtain the profile through the side proceed as follows: From B in elevation draw the vertical line B M, as shown, and from the divisions on the profile B C draw lines parallel to the lines of the moldings until they intersect the line B M, as shown by the small figures. From the intersections obtained on the miter line L G in plan, as before explained, draw lines parallel to H G indefinitely, cutting the miter line K H, as shown. In line with K L of the plan draw the line B′ M′, in hight equal to B M of elevation, and transfer the spaces from B M to B′ M′, as shown. At right angles to M′ B′ and from the points on same draw lines as shown, intersecting lines of corresponding numbers drawn from the miter line L G. A line traced through these intersections will be the desired profile through the side of the base. To obtain the pattern for the side proceed as follows: At right angle to H G draw the line B^3 N^2, upon which place the stretchout of the profile B′ N′, as shown by the small figures. It will be noticed that the spaces in the profile B′ N′ are of unequal distance, and must each be separately placed on the line B^3 N^2. Through the points in this stretchout line draw the usual measuring lines, as shown, which intersect with lines of corresponding numbers drawn at right angles to H G from the miter lines K H and L G. A line traced through these intersections, as shown by K′ H′ G′ L′, will be the desired pattern for the side.



Pattern for Molded Base.

Lyles & Mills of 231 William street, New York City, send us a copy of their enlarged catalogue of decorative metal ceilings. Within the colored paper covers of the publication some of the advantages of the use of metal ceilings over plastered work are given; also directions for putting up metal ceilings, together with illustrations showing their appearance when finished. The manufacturers have added new styles of plates, to which special reference is made in the catalogue. A number of designs of ceilings are presented, together with interior views of some of the buildings in connection with which work has been done. The firm state that they keep constantly in stock different styles of plates and moldings and can promptly fill orders with which they may be intrusted.

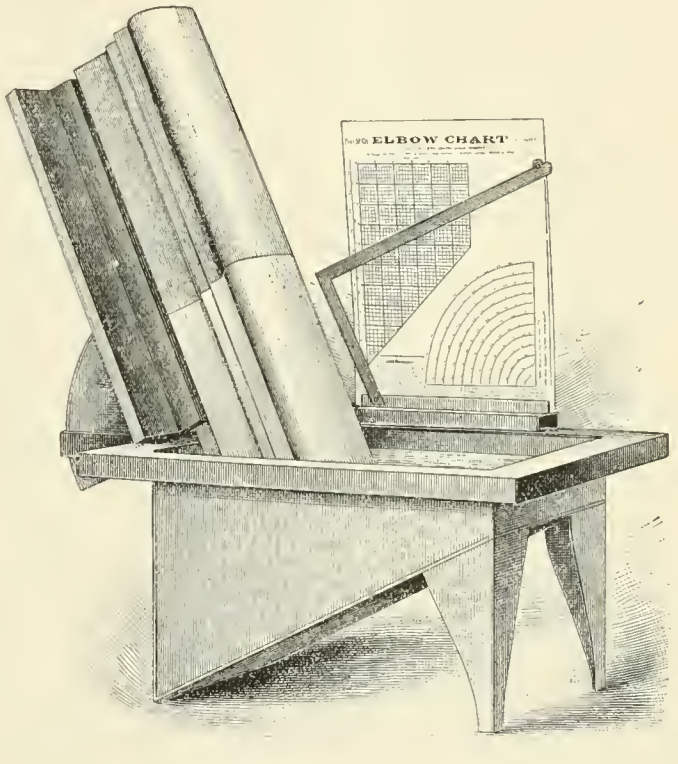
Water Line Patterns.

A year or more ago, our readers will remember, we illustrated a very complete chart devised by A. L. Burtis of Lockport, N. Y. Another application of this art is shown in the accompanying illustration and the following description of its use is taken from a letter received from Mr. Burtis:

As many of your readers are using my elbow chart, I send you a picture of a machine by which I make patterns for elbows or cornice miters when I want a pattern that is absolutely correct and want it quickly. It is the old water line method that I employ, brought down to an intelligent basis. By the use of a chart I can make 100 different patterns in one hour, and be able to write on each one just what it will make in two or more pieces when put together, and I don't know of any other way but this in which it can be done. The tank, of galvanized iron, is large enough to use for 12-inch patterns, being about 18 x 13 x 12 inches deep at the hinged end. I make it of the shape shown so as to require as little water as possible and do the business. I have tin cylinders made about 24 inches long of the different sizes of pipes, and just large enough to receive a paper covering so the edges will meet without any allowance for locks. To produce a pattern of 10-inch elbow, say in four sections of 84° angle, I set the bevel on the chart at one-third that number of degrees, or 28°. I then set the inclination to correspond with the bevel on the chart, slide the paper covered cylinder of that diameter down into the water, take it out and get the pattern while the water line shows plainly. If I have a piece of molding for which I want a miter, I wet one side, set the inclination by the chart, slide it into the water, and in less time than it takes to tell it I have an excellent pattern. Heavy building paper is just the thing for the elbow patterns and is cheap. The square I use on the chart is made of tin about ½ inch wide with a pin through the chart, and is arranged so as to bring the upper edge on a line with the point A. The arc back of the plane is also made of tin with holes through which a small nail is passed to hold it at any desired angle, the arc running through a slot made of hoop iron that is fastened to the back edge of the wooden frame.

I would suggest the importance of having the apparatus set perfectly level. This may be accomplished by making a water line all around, about 1 inch from the top, which will serve to level it by when filled up to that line. Another point which should be observed is to hold the cylinder or piece of molding perfectly true and upright, a gauge being fastened to the inclination for that purpose. Vertical lines should be drawn on the paper at each quarter of the circumference before wrapping around the cylinder, so that the pattern will be equally divided, and prick marks can be made on the pattern, which serve as a guide when putting the sections together. Then if a fish tail pattern is desired in four or more pieces, the seam on the paper will be held on one side, bringing the first quarter mark in front, while for a three-piece elbow, the seam would be held in front. In setting the inclination by the chart, follow the directions the same as if the pattern was to be drawn with a pencil. For a right angle four-piece elbow the upper line of the tin square would be set at 30° on the upright scale on the chart and the incline set parallel with the short arm of the square. The long arm of the square is held up by a hook made of tin, that slides on the top edge of the chart, and which admits of accurate adjustment. The chart is set on edge in a block of wood 2 inches wide by 10 inches long, and slides back and forth on the wood support. All of the parts are of the simplest construction, and can be quickly and cheaply made by any one desiring the most perfect pattern making device in the world for elbows.

Bowers, Galpin & Co., Binghamton, N. Y., publish circulars relating to their conductor pipe. One of these circulars shows illustrations, general and sectional, of their standard patent expanding galvanized conductors, which



Water Line Patterns.

are made square, chamfered and octagon, and of copper or galvanized steel. Similar illustrations are also presented of their heavy riveted expanding conductors for large buildings and which likewise are made square, chamfered and octagon. These conductors are made of 20, 22 and 24 galvanized steel and copper, strongly riveted, in 8 and 10 foot lengths without cross seams and with expanding lip from 1 to 1½ inches wide. They are made for business blocks, railroad and public buildings, and other places requiring heavy, strong conductor pipe.

Pen portraits of distinguished people are always entertaining and we therefore believe that many of our readers will be interested in the following sketch of a certain traveler in the tin plate trade. The portraiture is furnished us by a correspondent, who received it in a letter from a friend: "His appearance is striking in the extreme. He was 'set' behind a large diamond which gleamed in his bosom and reminded me forcibly of the description of the inhabitants of the Hall of Eblis in 'Vathek,' who, as you will remember, are described as having burning coals in their bosoms. His clothes were of unusual cut and a pattern nearly as pronounced as his manner. He swaggered about the store with a peculiar easy elegance and leered at our lady typewriter like a tailor-made satyr. He was pleased to patronize me in a very marked manner, and noticing I was English, he addressed me in a very bad imitation of the accent of the cockney costermonger, I suppose he intended it as a delicate compliment and I was sorry I could not return his civility by replying in a torrent of profanity in a nasal twang, *à la* American 'tough.'"

The North of England settlement of coal miners in the Monongahela Valley is said to be becoming depopulated by the departure for home of the Scotch families located there, of which some 40 have already departed, while others are on the point of leaving. The movement is caused by the recent severe reduction in wages, whereby they have been brought down to a lower rate than the miners could earn at home.

The Legislature of San Luis Potosi, Mexico, have decreed the exemption from all taxation of new industries locating in that district. The ordinance provides that all such industries established within the next five years shall be free from taxation for a term graduated according to the amount of the investment. It is hoped to stimulate the investment of foreign and especially American capital in the lands and mines of the State of San Luis. This example will, it is believed, be followed by other States of the Mexican Republic.

Accidents in and about coal mines in Great Britain during 1893 caused the death of 1056 persons, an increase of 40 over the record for 1892.

Work on the new cable between Nova Scotia and the coast of Ireland will be commenced shortly. The cable will be 2200 miles long.

THE TIN SHOP.

Pattern for Article Oblong to Round.

From G. M. L.—How is the pattern to be described for an article oblong to round, the round top to be tangent to oblong base at side and end? For example, the oblong base to be 20 x 51 inches, and the round top 32 inches in diameter.

Answer.—In Fig. 1, let A B C D represent the round top in plan, and F G H J the oblong base. The top is struck from E as center. In Fig. 2 the plan is shown in connection with the side and end elevations. For convenience in describing the pattern, divide the plan of top into four equal parts, as indicated by the lines A*a* C*a* B*a* D*a*, drawing A*a* C*a* through the center E*a*, and parallel with F*a* G*a*, also drawing D*a* B*a* through the center E*a*, at right angles to A*a* C*a*. Also connect J*a* D*a* H*a* and H*a* C*a* G*a*. The plan being thus divided, we can see that there are four sections of oblique cones in the article, as A*a* F*a* B*a*, B*a* G*a* C*a*, C*a* H*a* D*a* and D*a* G*a* A*a*. The sides and ends are in the form of triangles. Thus the side J*a* D*a* H*a* is shown in elevation by J*b* D*b* H*b*, and indicated in end elevation by J*c* D*c*. J*b* D*b* H*b* of side elevation is the exact shape of F*a* B*a* G*a* of plan, which is indicated in end elevation by F*c* B*c*. The exact shape of J*a* A*a* F*a*

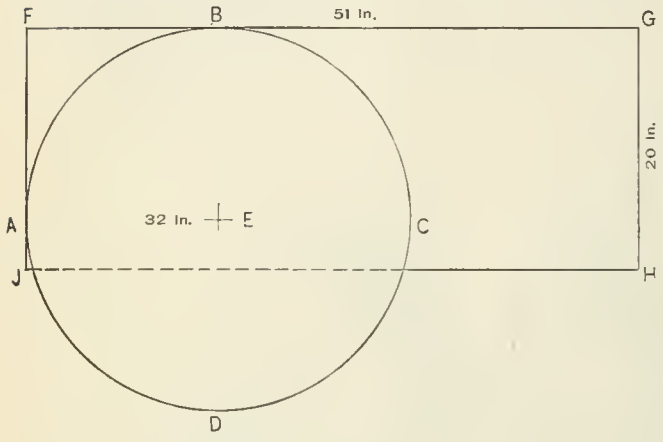


Fig. 1.—Plan Indicated by "G. M. L."

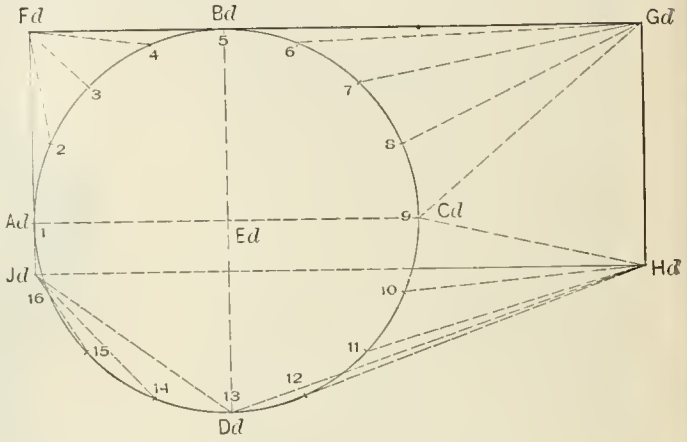

Fig. 3.—Base Lines of Triangles Drawn on Plan.

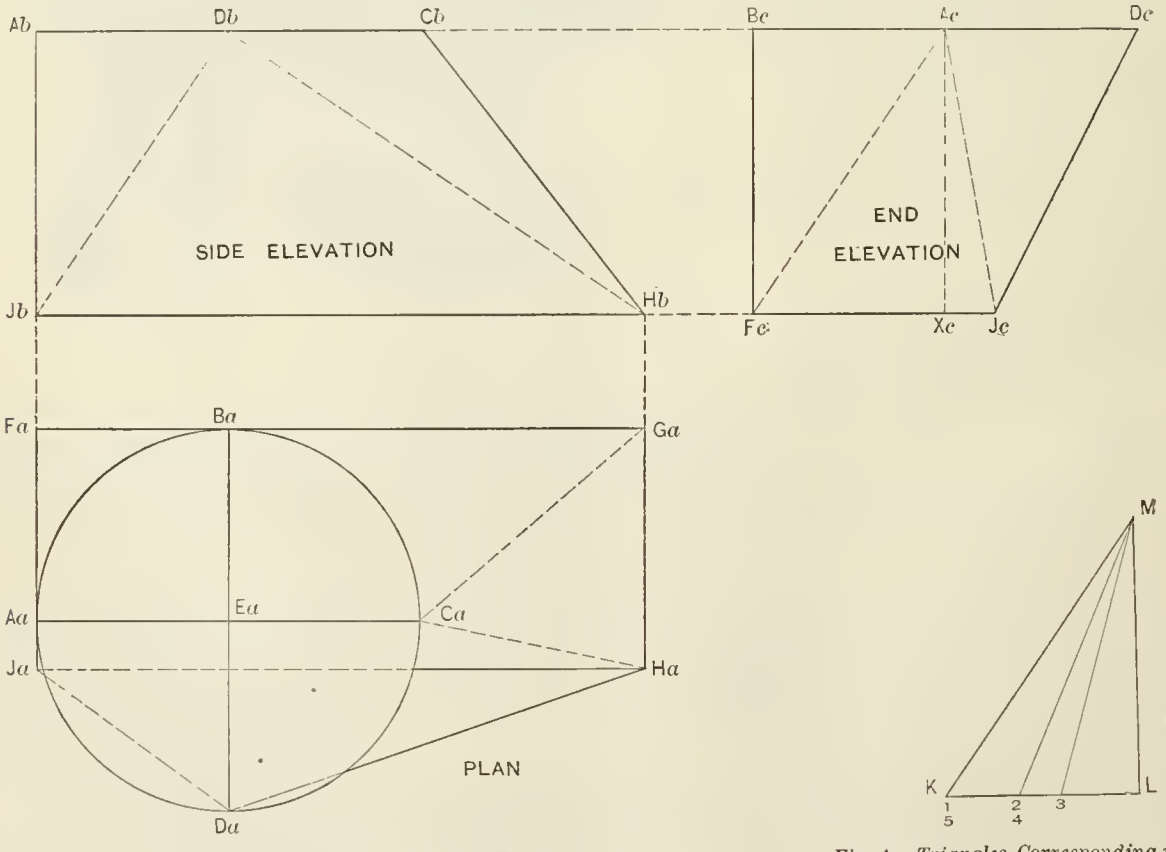

Fig. 2.—Plan, Side and Front Elevations.

Fig. 4.—Triangles Corresponding with Lines in Ad Fd Bd of the Plan.

PATTERN FOR ARTICLE OBLONG TO ROUND.

is shown in end elevation by F*c* A*c* J*c*, and indicated in side elevation by J*b* A*b*. The remaining end is shown in plan by H*a* C*a* G*a*, and indicated in side elevation by H*b* C*b*.

While the elevations are convenient in enabling one to understand the shape of the article, in the present instance they are not necessary in describing the pattern when the operation is performed by triangulation, the hight of the article being known. For the purpose of obtaining the base lines of the triangles divide the plan of the top into any convenient number of equal parts, as indicated in Fig. 3 by the small figures. Thus A*d* B*d* is divided into four parts, and from the points thus obtained lines are drawn to F*d*. As A*d* F*d* B*d* is part of an oblique cone we will construct a diagram of triangles whose bases are equal to the length of lines drawn from A*d* B*d* to F*d*. The altitude of these triangles will be equal to the hight of the article, so their hypotenuses will give the distances from F*d* in the base to the points in A*d* B*d* of top. We will pursue a similar course with the other sections. That a confusion of lines may be avoided, a diagram of triangles has been constructed for each of the parts of oblique cones, as shown in Figs. 4 to 6.

For the diagram of triangles in Fig. 4 proceed as follows: Draw any line, as M L, in length equal to the hight of the article. From the point L and at right angles to M L draw the line L K, and, measuring from L, set off the length of lines in A*d* F*d* B*d* of plan, Fig. 3. Thus L K is equal to F*d* A*d* and F*d* B*d*, and so on. From the points thus established in K L draw lines to the apex M. If the triangle M L 3 was placed with its base on F*d* 3 of plan its hypotenuse would give the distance from F*d* in the base to point 3 in the top.

The triangles in Fig. 5 are constructed in the same general manner. O P represents the hight of the article, as represented by J*b* A*b* of side elevation, and from O, on O N is set off the length of lines in B*d* G*d* C*d* of plan, and from the points thus obtained in O N lines are drawn to the apex P. The hypotenuses of the triangles in Fig. 5 thus represent the distances from G*d* of base to the points in top represented by the small figures. The triangles in Fig. 6 are constructed in a similar manner and correspond with the lines in C*d* H*d* D*d* of plan. When a pattern is to be described for any article it is well to first determine where the seam or joint is to be located. In the present instance the joint has been placed at A*d* in plan, Fig. 3, or as indicated by A*c* X*c* in end elevation. Accordingly the distance A*d* J*d* in plan has been set off from U in the diagram of triangles, Fig. 7, as indicated by U A. Then the hypotenuse A V represents the distance from the point J*d* in base to point A*d* in top. The remaining triangles in Fig. 7 are constructed in a

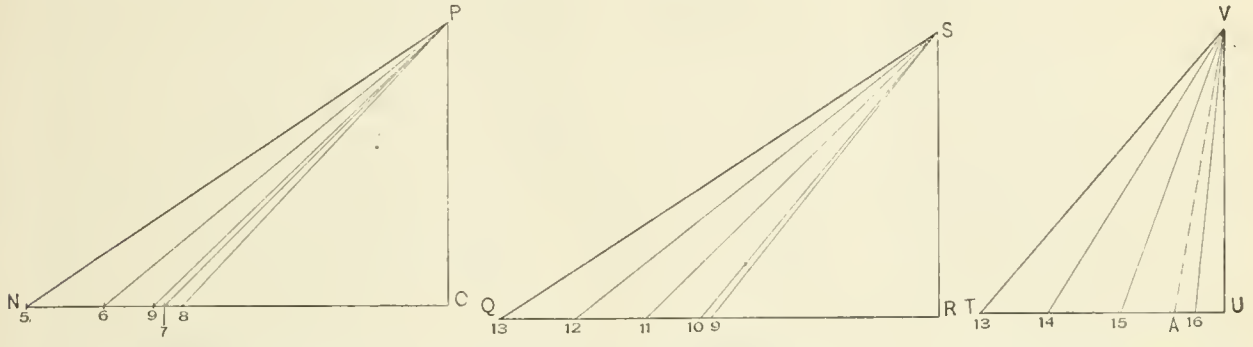

*Fig. 5.—Triangles Corresponding with Lines in B*d *G*d *C*d *of the Plan.*

*Fig. 6.—Triangles Corresponding with Lines in C*d *H*d *D*d *of the Plan.*

*Fig. 7.—Triangles Corresponding with Lines in D*d *J*d *A*d *of the Plan.*

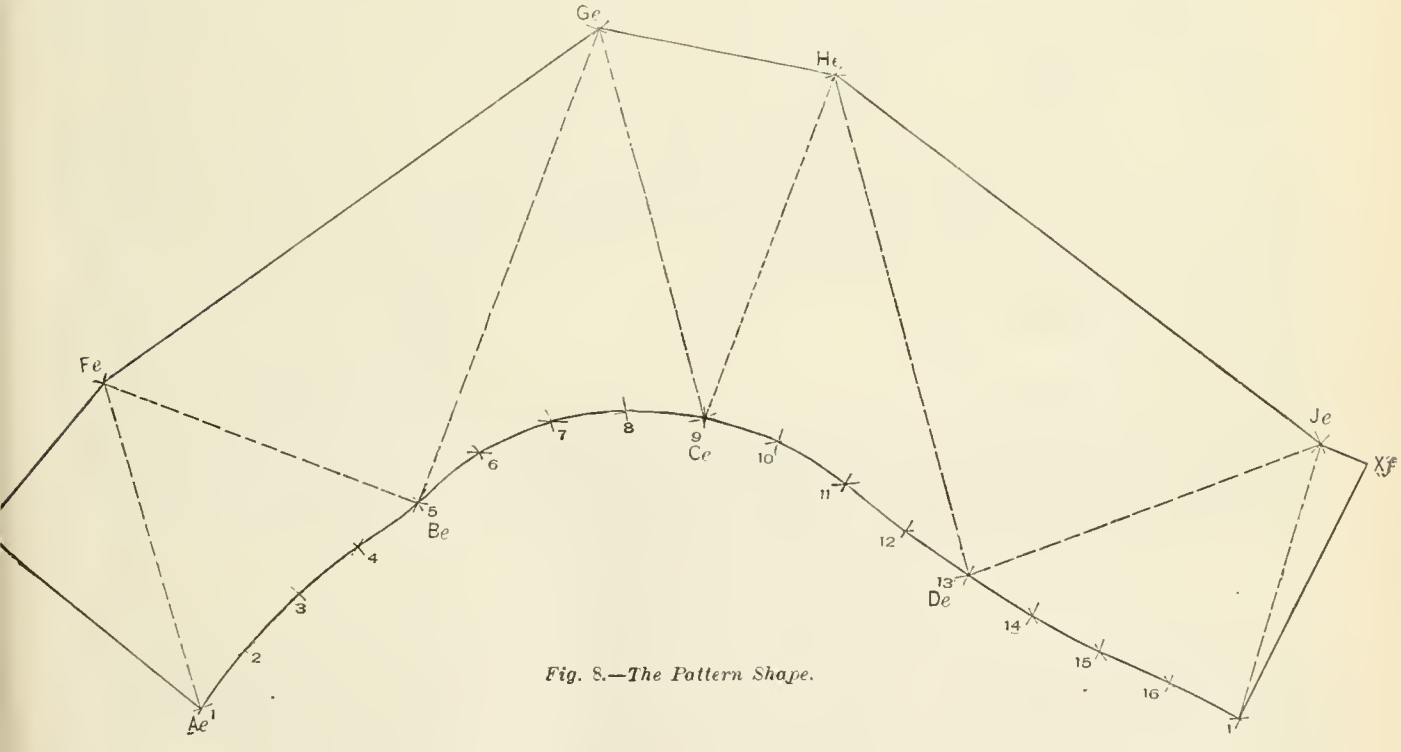

Fig. 8.—The Pattern Shape.

PATTERN FOR ARTICLE OBLONG TO ROUND.

similar manner and correspond with the lines in D*d* A*d* J*d* of plan.

For the pattern shown in Fig. 8 draw any line, as X*e* A*e*, in length equal to L M of first diagram of triangles, Fig. 4. With X*e* of pattern as center, and with A*d* F*d* of plan as radius, strike a small arc in the direction of F*e*, which intersect with one struck from A*e* as center, and M K of Fig. 4 as radius, thus establishing the point F*e* of pattern. Connect the points thus obtained, as shown. Then X*e* F*e* A*e* is the pattern of part of article shown in end elevation by X*c* F*c* A*c*, or indicated on plan by A*d* F*d*. With F*e* of pattern as center, and M 2 of Fig. 4 as radius, strike a small arc, which intersect with one struck from A*e* as center and the distance A*d* 2 of plan as radius, thus establishing the point 2 of pattern. Proceed in this manner, with the point F*e* of pattern as center, with radii corresponding to the hypotenuses of the triangles in Fig. 4, strike the arcs shown. With the dividers set to the same space as was used in stepping off the plan in Fig. 3, and commencing with point 2, step from arc to arc, as shown by the figures 2, 3, 4, 5. A line can be traced free hand through the points thus obtained, and the line F*e* B*e* drawn, as shown by A*e* B*e* F*e*. Then A*e* F*e* B*e* is the pattern for part of article shown on plan by A*d* F*d* B*d*.

With F*e* of pattern as center, and F*d* G*d* of plan as radius, strike a small arc, which intersect with one struck from B*e* of pattern as center, and P N of Fig. 5 as radius, thus establishing the point G*e* of pattern. Draw F*e* G*e* and G*e* B*e*. Then F*e* G*e* B*e* is the pattern of side of article indicated on plan by F*d* B*d* G*d*.

With the hypotenuses of the triangles in Fig. 5 as radii, and with G*e* of pattern as center, strike arcs as shown, and with the dividers set to the same space as was used in stepping off the plan, and commencing with B*e*, step from arc to arc, as shown by the figures 6, 7, 8, 9. Trace a line through the points thus obtained, as shown by B*e* C*e*, and draw C*e* G*e*. Then B*e* C*e* G*e* is the pattern of part of article shown on plan by B*d* G*d* C*d*.

With G*e* of pattern as center, and G*d* H*d* of plan as radius, strike a small arc, which intersect with one struck from C*e* as center, and with S 9 of Fig. 6 as radius, thus establishing the point H*e* of pattern. Draw G*e* H*e* and H*e* C*e*. Then G*e* H*e* C*e* is the pattern of part of article shown on plan by G*d* H*d* C*d*.

With H*e* of pattern as center, and with the hypotenuses of triangles in Fig. 6 as radii, strike arcs, as shown, and with the dividers set to the same space as was used in stepping off the plan, and commencing with C*e* of pattern, step from arc to arc, as indicated by the figures 10, 11, 12, 13. Trace a line free hand through these points, as shown by C*e* D*e*, and draw D*e* H*e*. Then C*e* H*e* D*e* is the pattern of part of article shown on plan by C*d* H*d* D*d*.

With H*e* of pattern as center, and with H*d* J*d* of plan as radius, strike a small arc in the direction of J*e*, which interaect with one struck from D*e* as center, and V T of Fig. 7 as radius, thus establishing the point J*e* of pattern. Draw H*e* J*e* and J*e* D*e*. Then H*e* D*e* J*e* is the pattern of part of article shown on plan by H*d* D*d* J*d*.

With J*e* of pattern as center, and with the hypotenuses of triangles in Fig. 7 as radii, strike arcs as shown, and with the dividers set to the same apace as was used in stepping off the plan, and commencing with D*e* of pattern, step from arc to arc, as indicated by the figures 14, 15, 16 1. Trace a line free hand through these points, as shown by D*e* A*f*, and draw A*f* J*e*. With A*f* of pattern as center, and V U of Fig. 7 as radius, strike a small arc in the direction of X*f*, which intersect with one struck from J*e* of pattern as center, and J*d* A*d* of plan as radius, thus establishing the point X*f* of pattern. Draw A*f* X*f* and X*f* J*e*. Then A*f* X*f* J*e* is the pattern of part of article shown on plan by J*d* A*d* and in end elevation by A*c* X*c* J*c*. It will be observed that A*d* of plan, Fig. 3, refers to similar points in base and top. In thus describing the pattern, points X*e* F*e* G*e* H*e* J*e* X*f* correspond with points A*d* F*d* G*d* H*d* J*d* A*d* of plan of base, as the points A*e* B*e* C*e* D*e* A*f* of pattern correspond with points A*d* B*d* C*d* D*d* in plan of top. As the net pattern only is shown, suitable allowances should be made about the edges for joining.

OBITUARY.

JAMES G. WELDON.

James G. Weldon, one of the best known residents of Pittsburgh, died at his home in the East End, in that city, on Friday morning, March 2. He was the senior member of the plumbing firm of Weldon & Kelly of 404 Wood street, and was an active member of the association of master plumbers, both national and local. It was while attending the national Executive Committee meeting of this association in Boston ten days ago that he contracted a cold which developed into pneumonia and caused his death. Mr. Weldon was born in Philadelphia in 1831 and came to Pittsburgh when a boy. He learned the brass molding trade and then entered the plumbing and gas fitting business, in which he had been engaged for 40 years. He was a member of the old Vigilant Volunteer Fire Company. For eight years he was a member of City Councils from the old Third ward, now the Fifth, and later represented the Fifteenth ward for five years. He was a member of the committees on water and streets when the present water works were started and the great improvements commenced. He leaves a wife, four sons and three daughters.

EATON, COLE & BURNHAM COMPANY, who last year went into the hands of receivers, have made a proposition to their creditors which contemplates payment in full, with interest, extending over a period of three and a half years. This offer has been accepted and the receivers, E. G. Burnham of Bridgeport, Conn., and E. H. Cole of New York, were, March 3, discharged by Judge Townsend of the United States District Court at New Haven.

SCRAP.

A WELL ATTENDED MEETING of the creditors of James B. Scott & Co., tin plate manufacturers, whose affairs were placed in the hands of James Collord, assignee, on February 13, was held in Pittsburgh on Tuesday afternoon, the 6th inst., at 3 p.m. It is understood that this meeting was only a preliminary one, and was for the purpose of giving the creditors a general idea of the condition of the affairs of the firm. A summary statement was presented, which showed that the liabilities of the firm would aggregate about $200,000, while the assets were given as considerably less than this amount. The statement was referred to a committee of three of the creditors, who will examine the accounts closely and call another meeting of the creditors when the report is ready. It is likely that this meeting will be held next week, when it is probable a proposition will be made to the surviving members of the firm by the creditors for the payment of the indebtedness of the concern. It is also probable that an effort will be made by which the business of James B. Scott & Co. will be carried on by the surviving members of the firm.

LYON, CONKLIN & CO. of Baltimore, Md., are putting on the market a roofing plate made of iron, under the name "Iron Old Way." This plate they claim is made from soft charcoal iron and carries a terne coating which is as heavy as it is possible to apply. It is claimed that the pores of iron being much more open than those of steel, the coating adheres better, thereby making the plate far less liable to rust. A sample section of a roof made of these plates has been subjected to a long exposure on a high roof surrounded by factory buildings, unprotected from the weather of the past winter, and upon examination no sign of rust or corrosion was apparent. The firm state that they are introducing the plate in response to numerous requests of architects and roofers, and after experiments extending over three years.

A. W. Brown, who recently purchased at assignee's sale the plant of the Ellwood Steel Company, at Ellwood, Pa., has contracted with the Leechburg Foundry & Machine Company of Pittsburgh for the necessary machinery to equip this plant for the manufacture of black sheets for tinning purposes. It is the intention to change the four sheet mills to four tin plate mills. There is also to be added an additional cold rolling mill, four doubling shears, two Mesta patent vertical squaring shears and one Mesta patent pickling machine. The plant, when completed, will be a modern four-mill tin plate plant and is expected to be ready for operations about April 1, with a capacity for producing about 25 tons of black sheets on three turns. The name of the concern will be changed in the near future to the Ellwood Tin Plate Company. It is probable that when the plant is in successful operation on the manufacture of black sheets for tinning purposes the necessary machinery will be added and tin and terne plates made.

THE RETAIL STORE.

Ice Cream Freezers.

The assortment of Ice Cream Freezers offered to the trade by the different manufacturers for the present season is substantially the same as last year, with the addition of one or two new Freezers and improvements in others. The manufacturers are giving their attention to improving the goods wherever there is an opportunity, especially in the way of more durable tubs, simpler and better protected gearing, easier methods of fastening and removing the gear covers and more thorough agitation of the cream. The following review of the market represents the Freezers offered by the leading manufacturers :

THE WHITE MOUNTAIN FREEZER CO.,

Nashua, N. H., are not introducing any feature especially novel this year in their Triple Motion White Mountain Freezers. The tubs are described as made of close grained, Northern grown, seasoned pine, bound with galvanized iron hoops, and after the tub is complete a chemical preparation is applied to make it absolutely water proof. The cans are made from a heavy grade of charcoal tin plate, all outside fittings are galvanized, and the gearing is completely covered. The dasher is of malleable iron, in two parts, which revolve independently of each other. The point is made that the cream is beaten all the time that the crank is turned, preventing the frozen cream moving around in the can and in the same direction. All inside parts are tinned. The company also make the Arctic Freezer, in the construction of which, it is stated, the same care is exercised in the selection of all raw material as for the White Mountain, and that no seconds are utilized in any way in the construction of the Arctic Freezer. It is explained, however, that the gearing of the Arctic being simpler enables the manufacturers to sell it at a much lower price than the White Mountain is sold for.

PEERLESS FREEZER COMPANY,

Cincinnati, Ohio, are manufacturing the Peerless, Giant and Zero Freezers for the coming season. The improvements in the line of Peerless Freezers make them, it is remarked, easier to run and absolutely salt water and oil proof. It is stated that the automatic vacuum dasher is so constructed that the cream is aërated, lightened and rendered free from granulation. The crank can be used on the top or side of the Freezer, and all parts are made to be interchangeable. The Giant Freezer is constructed on the same principle as the Peerless, only much heavier, and is designed for hotels, confectioners, boarding houses, &c. The Zero Freezer is referred to as full size and well made, having the gearing completely covered. The company's Freezers are made in sizes from 3 quart to 10 gallon.

THE SAMUEL C. TATUM COMPANY,

Cincinnati, Ohio, are offering the Ohio Freezer, Gooch's patent, in sizes from 2 to 25 quarts. The gearing is fully housed and so arranged as to prevent dirt or oil getting into the can. The shank of the dasher comes up through the housing, so that the crank may be used on the top or at the side. The can has a cast iron top with gearing on it (concealed under the housing) giving one motion to the can, while the reverse motion is given to the dasher. The dasher on one side has spiral projections, to thoroughly stir up the cream from the bottom, while on the other is a wood strip, which, in the action of turning the dasher, presses closely against the outside of the can to allow the entire contents of the can to be thoroughly stirred. There is also provision for preventing the dasher being turned backward.

NORTH BROS. MFG. COMPANY

of Philadelphia are making Shepard's Lightning, Gem and Blizzard Freezers, in sizes from 1 to 14 quarts. This year they have adopted for their entire line the electric welded wire hoop pails, the hoops of which they claim are twice as strong as flat hoops, and are guaranteed by the company not to fall off. The cap covering the gearing on the Gem Freezer is now made separate and is bolted to the cross piece instead of being cast solid. The pails are made, it is stated, of the best Virginia white cedar. All inside parts of Freezers are thoroughly coated with pure block tin and outside parts galvanized. The point is made that materials and workmanship are of the very best, and all Freezers are completely wrapped in heavy paper to protect them from dirt and dust in transportation and while in stock.

CHARLES W. PACKER,

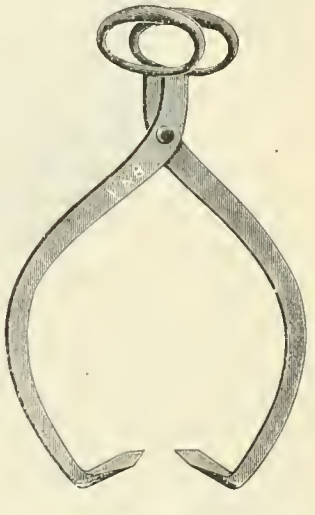
Philadelphia, is offering his Standard Freezers for families, confectioners, hotels, &c., in suitable sizes, the double action Freezers being made for hand or power. The automatic double acting vibrating scraper, which is used in all the machines, is described as adjusting itself closely to the inner surface of the can, removing the frozen cream as rapidly as formed, while the deflectors, lifters and cutters force the unfrozen portions to the sides of the can, causing continuous action upon the cream, by which the maximum amount of agitation is secured and the cream is thoroughly beaten. It is stated that the cans are made of the best quality, extra weight and heavily coated tin plate, the tubs of selected seasoned white cedar, the inside castings tinned, the outside castings galvanized, and that malleable iron fittings are used on the tubs.

V. CLAD & SONS,

Philadelphia, manufacture the Seamen Ice Cream Machine for hand and for power, with extra tub, can, beater and cover; also an extensive line of Philadelphia Ice Cream Machines for hand and for power, with and without engines, including 30 and 40 quart sizes. The cans for these Freezers are made of copper or tin. Freezers without beaters are made with wooden handle, malleable iron rims on body and cover and malleable iron bottom. The body is of DXXXX charcoal tin plate, with the rim around the top tinned. The concern also make Packing Cans, Carry Out Cans, porcelain lined Iron Cans, Cedar Tubs, extra heavy Shipping Tubs and a general line of Ice Cream Tools.

The V. & B Solid Steel Ice Tongs.

The cut herewith given shows the new ice tongs which have just been put on the market by the Vaughan & Bushnell Mfg. Company, 877 to 887 Carroll avenue, Chicago. These tongs are drop forged of solid cast steel, with no weld whatever. The handles are not only an integral part of the tongs, but they are also by this method made of a more



The V. & B. Solid Steel Ice Tongs.

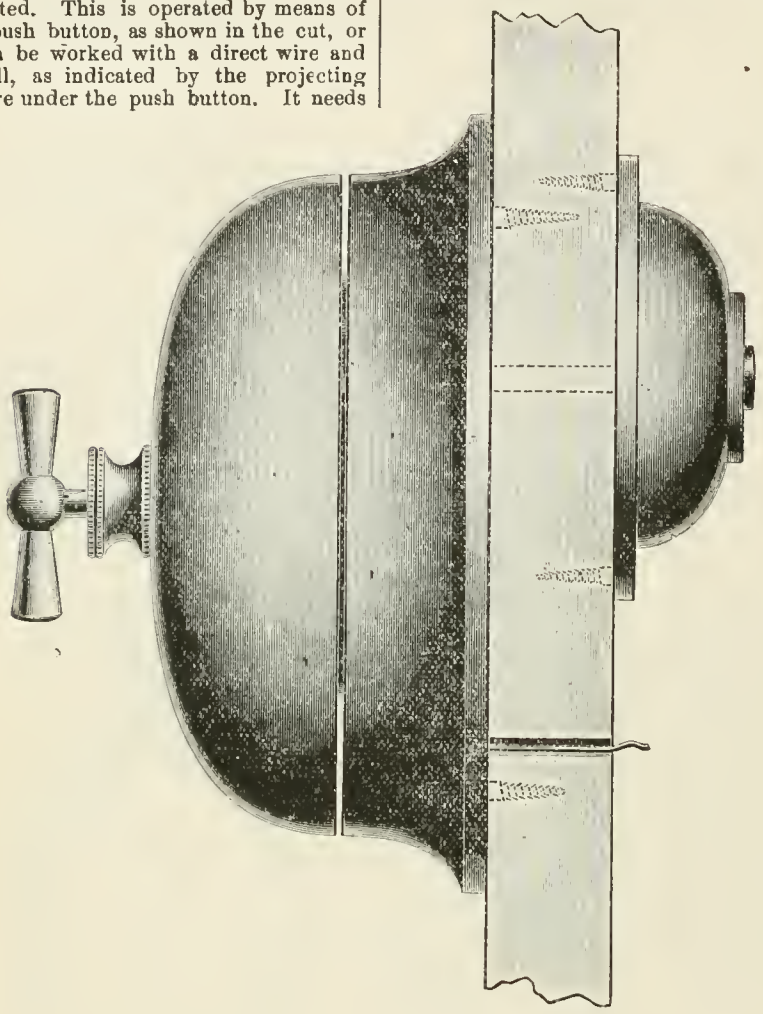
satisfactory shape. The upper portions of the rings are swelled to fit the palms of the hands and give the holder a firmer grip. These tongs are not only light but very stiff and strong. They are made in three sizes, opening 13, 17 and 24 inches.

Mangles.

S. C. Johnson, Racine, Wis., is offering mangles in three different styles, designed to take the place of sad irons for doing up linen and bedding. The smaller machine weighs 100 pounds and is suitable for use in small families. The Eclipse machines have rollers either 24 or 27 inches long; the 24-inch weighs 200 pounds, and the 27-inch 225 pounds; the machines being adapted to general use. The third style, the Domestic, is made on the same plan as these made in England, weighing 350 pounds, being especially adapted to hotel use. The manufacturer remarks that where there is any considerable quantity of linen and bedding to be ironed the mangles are quite a necessity; where there is only a small quantity they are a luxury. The point is made that the common method of using a hot sad iron does more or less scorch the fiber of the linen and turn it yellow, while linen ironed with a mangle has the appearance of always being new.

Electric Ring Door Bell.

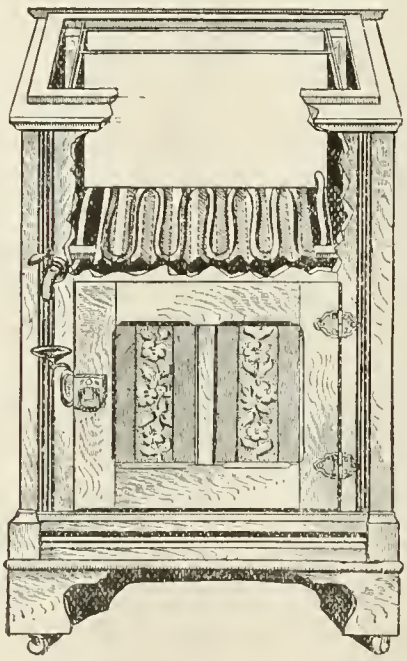
Sargent & Co., 35 Chambers street, New York, are offering a continuous electric ring door bell, as here illustrated. This is operated by means of a push button, as shown in the cut, or can be worked with a direct wire and pull, as indicated by the projecting wire under the push button. It needs occasional winding, which is done with the T-handle, seen at the left. It gives the sound of an electric bell, and will continue to ring (until run down) as long as the pressure is applied to the push button or the wire drawn by the bell pull. This is accomplished by a clock mechanism inside. The bells are packed one in a box, and finished in nickel, Yeddo bronzed and antique copper.



Continuous Electric Ring Door Bell.

National Refrigerator.

Page, Dennis & Co., 325 Broadway, New York, are introducing the National refrigerator, as here shown. They are manufactured under recent letters patent at their factories in Muskegon, Mich., shipments being made from either address. The line is an improvement on the American pattern long made by them, consisting in the arrangement and location of the porcelain lined water tank for supplying cooled water, together with the piping seen in the cut. This style has been perfected largely for domestic use where ice is expensive, as well as for exportation to warm countries. The tank is placed at the back of the ice chamber instead of at the end, giving about double the capacity, besides affording a clear way in putting in the ice. Cooled drinking water is drawn at the faucet through parallel lines of block tin pipe, which, being directly under the ice, is further refrigerated. A tight cover to the tank keeps the water from being contaminated by food odors. The corrugated ice rack slopes rearward, thus keeping the ice continually against the tank by gravitation. The side frames of the refrigerator run clear to the bottom, giving a firm support for the casters. The boxes are made in both soft and hard woods,

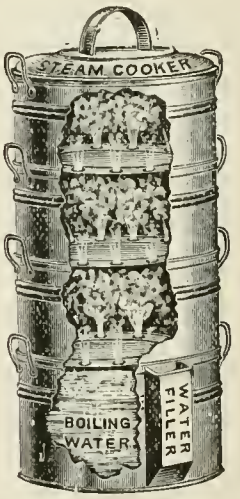


Sectional View of Water Tank and Ice Chamber of the National Refrigerator.

and for each size a mirror backboard or top is made, which, placed on the refrigerator, makes of it a sideboard. These tops are interchangeable and can be ordered at any time.

Pyramid Steam Cooker.

The cut here shown represents a steam cooker offered by Silver & Co., 304–310 Hewes street, Brooklyn, and 20 Warren street, New York. The cooker is made of IX tin, buffed bright on the outside, each cooker having one boiling and three cooking apartments. The different vessels can be used separately, as many at one time as is desired. The steam openings around the edge of each vessel are located in depressions or gutters, allowing the condensed steam to find its way back to the lower vessel along the sides rather than down the center and through other cooking foods. The manufacturers guarantee the device to cook an entire dinner of meats, vegetables, puddings, &c., at one time without attention and without imparting the flavor of one to the other; to economize nearly one-half in fuel and to be steamless and odorless and not to mingle the flavors. The steamer is made in three sizes: No. 1, vessels 8 inches in diameter, holding 2 quarts each; No. 2, vessels 9 inches in diameter, holding 3 quarts each, and No. 3, vessels 10 inches in diameter, holding 5 quarts each.



Pyramid Steam Cooker.

The National Chemical Works of Cragin, Ill., are manufacturing Bonnell's Nubian system of scale prevention in steam boilers. The Nubian scale prevention, as it is termed, is not a scale solvent, because the manufacturers claim that any article which will dissolve scale will injure the metal of the boiler. It has as its base tri basic sodium phosphate, with which are combined the proper ingredients to prevent scale formation. Its action is such as to prevent additions to the scale deposit and to cause the disintegration and dropping off of the old scale in a short time. The Nubian prevention is stated to be especially efficacious in marine boilers and others in which the cylinder oils get into the feed water. Prices and full directions for its use are given in a neat little pamphlet which has just been issued by the company.

Coal mines in Colombia are to be developed by a syndicate of American capitalists, the Colombian Government being a partner in the enterprise.

STOVE TRADE NOTES.

New England Stove Trade.

The condition of the stove trade of New England is only fairly satisfactory. The business of February was an increase over that of January and the outlook for March is regarded as more promising. At present the lines selling most freely are gasoline stoves, refrigerators and ranges. The manufacturers and jobbers are looking more and more to the furniture trade in this section, and this branch is probably handling in the neighborhood of 50 per cent. of all the stoves sold in New England. This is largely due to the growth of the installment idea, which is extending to many of the smaller towns and cities of the East. The regular stove trade for the most part refuse to do business in this way, but it seems to be a fixed thing in the furniture trade. Manufacturers of furnaces say that they find it almost impossible to induce retailers to contract for the season's supply. Heretofore, where an order for 10 to 20 furnaces to be delivered as wanted during the season has been booked, those needed for immediate requirements, with, perhaps, one for stock, are now bought and the future is left to take care of itself. This conservatism prevails in other lines as well and has a tendency to continue competition for orders indefinitely through the season.

The Baltimore Stove Trade.

There is not much activity among the manufacturers just now. Two foundries are closed for repairs and stock taking, and others are running on short time. There is a good deal of stock on hand left over from last season, and this will necessarily curtail the production for the coming season's business. The present demand for ranges and cook stoves is fair, but Western competition is very sharp on low priced goods. The season for summer goods has opened, but sales are small and there seems to be little disposition on the part of dealers to place orders early. The outlook for heating stoves for the coming season is, on the whole, very encouraging. Dealers have little or no stock on hand, as a result of careful buying during last season; and if business in general recovers itself before the fall trade sets in orders will assume fair proportions. Collections are not up to the average, but taking the existing depression into consideration, they are satisfactory; and there have been but few losses. Terms of settlement have in many cases been lost sight of completely, and much paper has been renewed for customers who have hitherto not had occasion to ask favors. There will be an increase next season in the production of furnaces, and a probable decrease in the production of the fire place heaters known as Baltimore heaters. Of late it has been found that the cheaper lines of furnaces have come into strong competition with Baltimore heaters. Building prospects in Baltimore are good, and while it is not expected that there will be a "boom," still it is anticipated that building operations will largely exceed those of other years, as the new trolley roads will render many desirable suburban building lots easy of access, and open to capitalists channels for investment. This will eventually benefit the stove and heating trades.

Comparative Cost of Operating Gas and Coal Stoves.

With the increasing use of gas as a fuel for cooking purposes no little discussion has ensued with regard to the cost of operating a stove burning gas as compared with one employing coal. In order to demonstrate what each could do under practically the same conditions, tests were recently made and a table of the results prepared under the direction of the United Gas Improvement Company of Philadelphia. The figures show a comparison between the cost of operating a gas and coal range, cooking three regular meals per day. Below we present the table as it appeared in a recent issue of the *Progressive Age:*

Gas Range.

	Dinner.	Lunch.	Breakfast.
Meat	Roast beef, 5 pounds 7½ ounces.	Mutton chops, 2 pounds 3½ ounces	Beefsteak, 1 pound 8 ounces.
Potatoes	Browned, 1 pound 4 ounces.	French fried, 1 pound 4⅝ ounces	French fried, 1 pound 5½ ounces.
Biscuit	2 pounds 3 ounces.	2 pounds 5½ ounces	2 pounds 4 ounces.
Tomatoes	1 quart stewed.		
Corn	¾ quart stewed		
Peach pie	Baked, 1 quart peaches		
Coffee—Tea	1 quart.	1 quart.	3 pints.
Water for washing dishes	10 pounds.	10 pounds.	10 pounds.
Total time	1 hour 30 minutes.	40 minutes 30 seconds.	46 minutes.
Total gas used	31 34 cubic feet.	16.16 cubic feet.	20.38 cubic feet.

Coal Range.

	Dinner.	Lunch.	Breakfast.
Meat	Roast beef, 4 pounds 13½ ounces.	Beefsteak, 2 pounds 10 ounces.	Mutton chops, 3 pounds 4 ounces.
Potatoes	Browned, 1 pound 5 ounces.	French fried, 1 pound 5 ounces.	French fried, 1 pound 6 ounces.
Biscuit	2 pounds 9 ounces.	2 pounds 8 ounces.	2 pounds 12 ounces.
Tomatoes	1 quart stewed		
Corn	¾ quart stewed.		
Peach pie	Baked, 1 quart peaches.		
Coffee—Tea	1 quart	1 quart.	1 quart.
Water for washing dishes	10 pounds.	10 pounds.	10 pounds.
Total time	1 hour 37 minutes	1 hour 16 minutes.	1 hour 5 minutes.
Solid fuel	¾ bundle wood, 12 pounds coal.	¼ bundle wood 6.68 pounds coal.	1 bundle kindling, 12 pounds coal.

Gas Range.—Biscuits were evenly browned without being moved; average time in oven, 13.8 minutes.

Weights of potatoes and biscuits were taken after being cooked.

Roast nicely cooked but quite rare in the center.

First weight of roast	5.445 pounds.
Second weight of roast and drippings	4.758 pounds.
Loss = 12.6 per cent. =	0 687 pounds.
Total gas per day =	67.88 cubic feet.
Cost per day at $1.25 per 1000 =	8.483 cents.
Difference between cost of coal and gas =	4.721 cents.

Coal Range.—Biscuits were not well browned on the bottoms; average time in oven, 8.8 minutes.

Weights of potatoes and biscuits were taken after being cooked.

Roast was overdone on the outside and too rare in center.

First weight of roast	4.85 pounds.
Second weight of roast and drippings	3.86 pounds.
Loss = 20.4 per cent. =	0.99 pound.
Coal used per day =	30.68 pounds.
Two bundles kindling at 2 cents =	4.000 cents.
Cost coal at $6 (anthracite) =	9.204 cents.
Total	13.204 cents.

Coal cost 55.6 per cent. more than gas.

The Chicago Stove Trade.

Whatever diferences of opinion may exist among the managers of the Chicago stove houses on most subjects, substantial unanimity prevails with regard to the condition of business at present. It is exceedingly quiet. January and February fell considerably below the corresponding months of last year in volume of business, and March does not show much improvement. The month is young, it is true, and the advent of

spring weather may tone up the stove trade just as it favorably affects other branches of business, but if it does the trade will be agreeably surprised. Travelers are out soliciting business, but they are mainly introducing new cook stoves and ranges, with a view to getting their special points well understaod by dealers, as an essential preliminary to the fall campaign. In this respect some houses may be said to be quietly accomplishing much good, as they have not permitted hard times and dull trade to blunt their enterprise, but are offering new and improved patterns with as much confidence in a large trade later on as they have displayed in previous seasons.

Generally speaking, the volume of business in the early spring months is not expected to attain any considerable proportions, so far as coal and wood goods are concerned. In fact, some managers assert that if they were to withdraw from the field entirely during these months their year's business would hardly suffer, except so far as laying plans for the fall and making arrangements for the heavy business of that season might be interfered with. The vapor, oil and gas stove manufacturers are to a great extent responsible for this. Every year they seem to be making more headway in the spring and summer trade. Their business is now of large proportions. They are notifying their agents now that if they desire prompt shipments their orders must be sent in a sufficient time in advance to give some leeway. This is particularly true of vapor stoves, which have latterly been concentrated in fewer hands.

As might be expected, the hard times and the consequent necessity for economy have greatly increased the demand for stove repairs. The cogent statement is made that coffins and stoves are the last things to be bought. Every effort is made to postpone the purchase of a new stove. All sorts of odd castings are now being called for, some of which have not been in demand for years. This shows that parts of stoves are being renewed which in good times would cause owners to discard the stoves and buy new ones rather than go to the considerable expense entailed in taking their stoves apart and reconstructing them. It makes no difference whether the stove is 10 or 30 years old, the manufacturer is expected to supply the part desired, and is severely censured if he cannot furnish it on the day it is called for. Much annoyance and vexation of spirit are caused these days by almost unreasonable requests for repairs to very old patterns, and the manufacturers are strongly tempted to adopt a rule that no repairs will be furnished for stoves more than ten years old.

Strong hopes are entertained of a good year's business in 1894. The gradual resumption of work by manufacturing establishments, the prospects of considerable activity in the building trades, and above all the belief that the very worst of the great business depression is over, are good grounds for hope in the future. Even the low prices now ruling for farm produce must show an improvement ere long in the nature of things, and if farmers are again prosperous there will be no element lacking that is really necessary to sustain trade.

Cupola Management.*—VI.

BY DR. EDWARD KIRK.

Charging.

The old way and the way still in vogue in some localities of stocking, loading or putting the fuel and iron into a cupola is to place a sufficient quantity of fuel in a cupola to fill it above the tuyeres. On this fuel or bed is placed from 50 to 500 pounds of iron, according to the size of the cupola, then from one to four shovels of fuel are put in and from 50 to 200 pounds of iron, and so on until all the iron to be melted is placed in the cupola.

This way of stocking a cupola mixes the fuel and iron in the cupola and they come down to the melting point together. The fuel fills a space that should be filled with iron, and a great deal of the melting surface of the cupola is lost, and the cupola's melting capacity reduced in proportion.

The modern way of stocking a cupola is to put in the fuel and iron in layers or charges. Each layer or charge of fuel is separated from the layer or charge above and below it by a layer or charge of iron, and each layer of iron is separated by a layer of fuel. This way of stocking a cupola is known as charging the cupola. When a cupola is charged in this way the iron comes down to the melting point in a body extending over the melting surface of the cupola, and the entire melting surface is utilized. The melting capacity of a cupola is about one-half greater when charged in this way than when the fuel and iron are mixed and the consumption of fuel is also less.

The first charge of iron is placed on the bed at the melting point. In melting this charge of iron a certain amount of fuel is consumed and the top of the bed settles down from the top of the melting zone to the bottom of the melting zone. The charge of fuel on top of the charge of iron that has just been melted settles with the iron until it unites with the bed and places the top of the bed again at the top of the melting zone, ready to melt the next charge of iron, and so on with each succeeding charge of fuel and iron through the heat. This is the correct theory of melting iron in a cupola, and the practice that must be followed to obtain the best results from a cupola.

Now, having described the theory of charging and melting, let us consider the practical working of a cupola upon the theory. The amount of iron placed upon the bed in the first charge and in each charge through the heat must be the exact amount of iron the fuel will melt while settling from the melting point to the bottom of the melting zone. The amount of fuel in each charge must be the exact amount required to raise the bed from the bottom of the melting zone to the melting point. If the charges of iron are made too heavy the iron comes dull at the latter end of the charge and hot at the first of the charge until a few charges have been melted, then it comes dull all through to the end of the heat. When the charges of iron are too light the iron comes hot, but there is a stoppage in melting at the end of each charge, changing to continuous but very slow melting as the heat progresses.

When the charges of fuel are too heavy the iron melts slow and uneven, and if the heat is a long one it comes dull and is hardened in melting. When the charges of fuel are too light and the charges of iron heavy the result is dull iron. When the charges of fuel and iron are both too light the iron generally comes hot but slow through the heat, and the full melting capacity of the cupola cannot be realized.

There is no rule for making the weight of the first charge of iron of any definite proportion to the weight of the bed of either anthracite coal or coke that holds good in all cupolas. Manufacturers of some of the patent cupolas have such a rule for their cupolas that is approximately correct, but the tuyeres in different sizes of these cupolas are always placed at the same hight and about the same amount of fuel is required for a bed. The bed will melt a heavier charge of iron in settling than the other charges of fuel and the first charge is generally made from one-third to one-half heavier than the subsequent charges. The weight of the first charge of iron varies from two and one-half to four and one-half times the weight of the bed with anthracite coal; with coke the weight of the first charge varies from one and one-half to four and one half times the weight of the bed.

These wide variations in the weight of the first charge of iron in proportion to the weight of the bed are largely due to the difference in the hight of tuyeres and the large amount of fuel required for a bed in a cupola with very high tuyeres. But variation is also due in many cases to bad judgment in estimating the weight the first charge should be. The greater the weight of the first charge in proportion to the weight of the bed, the better the average will be in melting, and careful experiments should be made with every cupola to learn the largest amount of iron it will melt on the bed with safety, and that amount should always be placed in the first charge.

There is no rule for making the weight of the charges of fuel or iron of any definite proportion to the weight of the bed or first charge of iron, and the weight of the charges of both fuel and iron are frequently changed in different parts of the heat, to give a hotter iron for some special work or to make the iron run of an even temperature through the heat. In practice, the weight of the charges of iron to the charges of anthracite coal varies from 6 to 14 pounds of iron to the pound of coal. With coke they vary from 6 to 15 pounds of iron to the pound of coke. These variations in the per cent. of iron to fuel are due in many cases to the quality of fuel and in many other cases to poor judgment in working the cupola. In all cases the charge of iron should be made as heavy as the charge of fuel will melt and produce good hot iron for the work, for this is the only way a good per cent. of iron to the pound of fuel can be obtained.

Placing the Charges.

The top of the bed is made as level as it can be before charging the iron, and the smoke must all have disap-

*Copyrighted, 1894, by Dr. Edward Kirk.

peared so the melter can see how to place the charges. When the cupola is very high a few hundred of stove plate or other light scrap is placed upon the bed to prevent the heavy pieces of pig or other iron breaking up the fuel and settling down into the bed when thrown in. The pig should be broken into short pieces and placed in the cupola with the end toward the lining. The pieces of pig or other iron are placed close together so as to utilize all the heat and prevent its escape up the stack, and each charge is made as level as it can be on top. The gates and cupola scrap are placed on top of the pig and are used to fill up holes and level up the charge. Old scrap is generally charged with the pig when heavy, and on top of the gates when light. Rattle barrel iron and gangway scrap or riddlings goes in with the gates a few shovels to each charge.

The charge of fuel is distributed evenly over the charge of iron, and the second charge of iron is put in the same as the first, and the second charge of fuel the same as the first, and so on until the cupola is filled to the charging door. Charging is then stopped and the door closed until the blast goes on. When melting begins the stock begins to settle, and the door is opened and charging continued as before until all the iron to be melted is placed in the cupola. While charging is going on the cupola is kept filled to the charging door to prevent the gas igniting and making a hot flame at the charging door, which makes it hot for the men and difficult to place the charges of fuel and iron properly. When charging is finished the charging door is closed to prevent sparks or pieces of burning fuel being thrown upon the scaffold.

When the iron is all or nearly all melted that has been charged, and it is discovered there is not sufficient iron in the cupola to pour off the work, more iron is sometimes charged. At this stage of the heat the stock is so low in the cupola and the heat is so intense that the cupola is in a very bad condition for resuming charging to melt more iron. It is only a waste of fuel to charge it into the cupola at this stage of the heat, and the only iron that can be melted on the fuel already in the cupola is the light scrap, and but a limited quantity of it. When the charging door is opened the heat at the opening is so intense that the men cannot go near it, and the scrap must be thrown in from a distance or by standing alongside of the cupola out of the heat and throwing the iron around into the door on a shovel.

Poor melting may be due to bad charging. Iron or fuel should never be dumped into a cupola from a barrow, for it all falls on one side of the cupola The iron generally lays where it falls in a pile, and the fuel rolls to the other side of the cupola, and good melting cannot be done with the fuel on one side and the iron on the other. This way of charging is about equal to the old way of mixing the fuel and iron, and only about one-half of the melting capacity of the cupola can be realized. Fuel should never be emptied into a cupola from a basket or box, for it all falls in one place and cannot be spread evenly over the charge of iron. To charge a cupola properly the iron must all be thrown in with the hands and the fuel with a shovel or fork.

Charging Flux.

When it is desired to tap slag the slag producing material or flux is charged in the cupola on top of the iron and evenly distributed. The flux is sometimes put on each charge of iron, but generally about one-sixth of the heat is charged without flux. After that, flux is put in on every charge of iron except the last one or two charges, where it is not required if the proper amount has been used through the heat. The quantity of flux required depends upon the slag producing propensity of the material used and the condition of the iron charged, and is from 30 to 100 pounds to the ton of iron melted. If the iron to be melted is all clean iron the amount of flux required is less than when the iron is dirty scrap or a large per cent. of the heat is sprues and gates that have not been milled and are melted with a heavy coating of sand on.

If it is not desired to tap slag and the flux is used only to make a brittle slag in the cupola, it is charged in small quantities of from 5 to 10 pounds to the ton of iron, and is placed around the outside of the charge near the lining. Flux is sometimes charged in a cupola in a sufficient quantity to produce a large body of slag through which to filter the molten iron and cleanse it of impurities, but not in a sufficient quantity to admit of slag being drawn from the cupola. This way of fluxing works very well in a short heat, but in a long heat the slag sometimes absorbs a large amount of impurities, becomes overheated and boils up in the cupola and fills the tuyeres, and when boiling the slag cannot be drawn from the cupola at the slag hole and the bottom generally has to be dropped.

ODD PLATES.

Henry N. Clark, 103 and 105 Blackstone street, Boston, is pushing the North Star Refrigerator and Central Oil-gas Company's full line in the New England States.

The Ridgway Furnace Company of 76 Union street, Boston, Mass., are offering the Ridgway revolving open fire pot furnace in substantially the same form as last season. The furnace was shown at the 1892 exhibition of the Massachusetts Charitable Mechanics' Association and was given the only gold medal awarded furnaces alone in 35 years.

One of the largest retail stores in the Northwest is known as the Rialto, recently built in the city of Seattle, Wash., this structure having a frontage of 240 feet and a depth of 110 feet. The proprietors of this establishment are agents for the goods made by the Peninsular Stove Company of Detroit, Mich., and have started out under most flattering prospects.

At the annual meeting of the Foster Stove Company, recently held at Ironton, Ohio, Charles Alexander was elected a director in place of his father, lately deceased. Mr. Alexander was also appointed foreman of the works.

The William Miller Range & Furnace Company of 9 and 11 West Fifth street, Cincinnati, Ohio, favor us with a copy of a catalogue of 12 pages, relating to a new line of wrought steel ranges which they are putting on the market this season. The line is made under the name "Vigilant," and has been brought out to meet a growing demand for a "well made, well finished, substantial and economical range, which would be a first-class roaster and baker, and could at the same time be sold at a price that would bring it within the reach of any one who might be in want of a first-class cooking apparatus." The Vigilant is intended for burning soft coal or hard coal or wood, and embodies among its features of construction drop oven and feed door with warming oven underneath, patent double centers, improved reversible duplex grate, regulating damper, gravity latch, sliding braces for supporting the oven door and asbestos lined flues. The range is shown in a number of varieties in the pamphlet at hand, one style being intended for burning wood only and made with extended fire box. The last page of the pamphlet is devoted to the Puritan range, which is a member of the same general class as the Vigilant, but is made in two sizes only.

The William Miller Range & Furnace Company of Cincinnati, Ohio, have just secured a large contract for heating apparatus for a private residence. The equipment calls for Miller-Monitor steel warm air furnaces sufficient to heat a $50,000 residence now in course of erection at Lafayette, Ind. We understand that the contract was secured against very severe competition.

In the death of George H. Pickering, which occurred a short time ago, the stove trade has lost a well-known member, and a veteran traveler. For some 21 years he represented the Spicer Stove Company of Providence, R. I., and during a period of nearly 11 years visited the trade in Eastern Massachusetts, Connecticut, Rhode Island and Long Island. He was a favorite with all who knew him and his sudden death after a week's illness was a shock to his host of friends. He was 45 years of age and a member of the Grand Army of the Republic.

We have received from the Excelsior Mfg. Company, St. Louis, Mo., a large pamphlet of several pages, which is designated by the company as "The Missing Link." In explanation it is stated that the missing link between the seller and buyer is already well known, and that it is not necessary to go to the wilds of Africa to find it. "There is nothing like it to bring the seller and the buyer into the right relationship and the magic word representing so much is 'Advertising.'" This is the keynote of the pamphlet, the pages of which are devoted to cuts suitable for use in connection with advertising matter by the dealer handling Charter Oak stoves and ranges.

The Rapid Transit Stove & Furnace Company, successors to J. B. Oldershaw of 628 North Eutaw street, Baltimore, Md., are looking for premises adapted to the requirements of a stove foundry. They propose, as soon as located, to commence the manufacture of Rapid Transit, Grand Rapid and Resplendent fire place heaters, Rapid Transit stoves and double heaters, Rapid Transit hot air furnaces, Diffusive heating stoves, ventilating register frames and chimney caps under the patents held by J. B. Oldershaw. The goods are all specialties and have a good local reputation. The company will locate in Baltimore, Philadelphia or some other point where good manufacturing and shipping facilities may be obtained.

The B. C. Bibb Stove Company of Baltimore, Md., have closed their works for stock taking and repairs. They will commence running again in a few days. They expect to have some additions to their well-known line of goods in readiness for the opening of the coming season.

THE PENINSULAR STOVE COMPANY of Detroit, Mich., send us a circular illustrating a plain finish wrought steel range, which they have just placed upon the market. They state it is neither cheaply made nor inferior in any way, but well built and substantial. It has draw out grate and asbestos lined flues, together with other features which, judging from the extensive sample orders received by the company, are making it popular wherever introduced.

A LARGE COLORED CARD is sent through the mail by Eugene Munsell & Co. of 218 Water street, New York, which measures 6¾ x 9¼ inches, and bears upon one side an announcement relative to the Manhattan stoves, ranges and furnaces made by the concern named, as well as an indication that they are also headquarters for mica. Below the announcement are blank lines for the name and address of the person to whom the card is sent. On the other side, at the left, is contained a picture of a steam whistle, and the statement that it is unnecessary for one of these devices to be in full blast all the time in order to make its presence known. Neither is it necessary that the person whose name is signed to the card should indicate his intended visit to the trade on or about blank date by noisy statements oft repeated. The announcement is signed by Charles E. Coleman, representing Eugene Munsell & Co.

Adjustable Motor Thermostat.

We show in the accompanying illustrations a plan view and elevations of the adjustable motor thermostat made by E. Barney, Schenectady, N. Y. The device consists of a sensitive blade mounted upon a japanned metal plate upon which are fastened brass contact

Adjustable Motor Thermostat.—Fig. 1.—Sensitive Blade.

posts and binding connecting posts properly equipped for motor connections. The sensitive combination blade, Fig. 1, is supported upright by a brass post, as shown in Fig. 2, which is an elevation of the device. The brass post

Fig. 2.—Elevation of Thermostat.

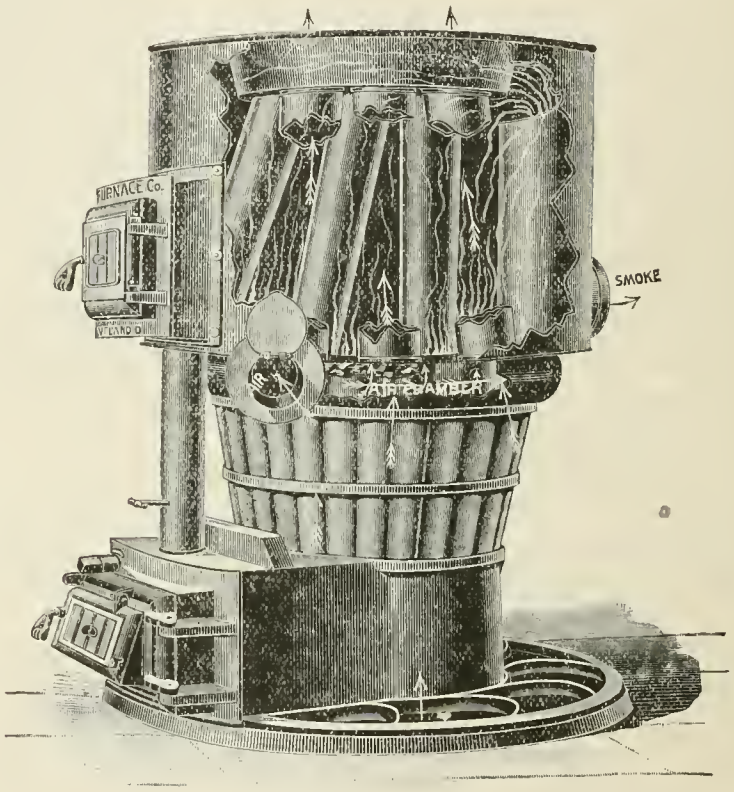
at the end of the blade fits in a socket and is held by a set screw, as shown. This arrangement permits the operator to adjust the blade to the right or left at will and securely fasten it in the proper position. Fig. 3 is a plan view

Fig. 3.—Plan of Thermostat without Blade.

of the device without the blade. At the front end, as shown, are two stationary contact posts, each having a working screw through it and between the points of which the front end of the thermostat blade works. For heat the blade moves to the right, for cold to the left. At the rear of the thermostat plate are three binding posts connecting the thermostat with the battery and motor. When the contact point of the thermostat blade moves to the right or left it touches the point of the screw, closing the circuit, which releases the motor that works the damper. The screws passing through the contact posts being adjustable, may be set to any degree of heat required.

The Fox Soft Coal Furnace.

The Fox Furnace Company of 28 Vincent street, Cleveland, Ohio, are offering the trade a heater for using soft coal and which represents the results of many years' experience with this kind of fuel. The manufacturers state that by means of a gas ring, which is placed between the upper section and the radiator of the furnace, an air chamber is formed which leads to the outside of the casing. Through this connection a current of air is taken and passed over the heated surfaces of the furnace, being raised in its progress to a high temperature. It is then introduced through openings into and above the fuel while in process of combustion, giving "a supply of heated oxygen which, combining with the gases of the coal, cokes the coal and consumes the gases of which the smoke and smudge consist." The makers claim that by this means soft coal can be burned with entire success and with but little smoke or soot beyond that of hard coal. The furnace is provided with the Smyth triangular bar grate, well known to the trade; the fire pot is made in two sections, each of which is heavily corrugated, while the radiator is made of steel plate, provided with a series of heavy cast iron ducts or tubes running from the outside at the bottom to the center at the top, passing the air to be heated directly over the center of the fire pot, thus warming it with great rapidity. All parts of the radiator, including the air tubes, are protected by a constant current of air which, in proportion to the size of the fire, passes over them with greater or less rapidity. The dampers are so constructed that by means of a nickel plated regulator they can be opened and closed from the upper floors. The casings are made double, with an air space, allowing for circulation between them, and thus reducing the radiation into the cellar to a minimum. The illustration which we present herewith shows the Fox soft coal furnace with the outer casing removed, clearly indicating the internal arrangement. The heater is made in



The Fox Soft Coal Furnace with Outer Casing Removed.

five sizes and is especially adapted for use in low cellars.

The White Star Steamship Company, in a letter to the New York Dock Board requesting increased pier accomdations, announce that they are contemplating the construction of a ship whose length will be about 640 feet, but it will be impossible for them to proceed with the plans of this vessel until they are assured of obtaining adequate pier space. This company, says the New York *Marine Journal*, handled last year some 900,000 tons of cargo and over 100,000 of coal, their wharf expenses, labor, &c., amounting to nearly $500,000.

The climax of unreasonableness in the way of strikes seems to have been reached recently at Providence, R. I., where 300 unemployed and needy men were given work at $1 a day by the Commissioner of Public Works. On finding that they were required to work for ten hours a day the whole gang struck rather than work over nine hours.

TRADE REPORT.

The Iron Market.

The monthly statistics of Pig Iron, published in *The Iron Age*, show that February recorded an increase of close to 11,000 tons in the weekly capacity, and it is well known that west of the Alleghanies and north of the Ohio further additions to the number of active plants have been made since March 1, and that more are coming.

So far as is known no contracts have yet been made for non-Bessemer Lake Ores, so that the capacity of the furnaces in the Central West making Foundry and Forge grades to pound the markets of the country cannot yet be gauged. It is, sure however, that considerable displacement will take place.

With Steel Billets back to $15.25, Pittsburgh, and at correspondingly low prices in the East, and with Finished Iron and Steel at the lowest prices, the near future does not look rosy. Some encouraging talk is indulged in, but no facts are brought forth to convince those who would be only too glad to accept brighter views.

Pig Iron.—Current business in the New York market is light, and no large contracts have been recently placed. An interesting fact is that Carrie, a Pittsburgh Iron which was quite well known in this market in past years, is again being offered. On the basis of Pittsburgh open quotations for Foundry Iron competition from that source in this market would be out of the question. No Pipe contracts of any consequence have been placed, except one lot of 600 tons for Warren, Pa. We understand that the East River Gas Company propose to lay a very large mileage of Cast Iron Pipe in this city this year. The company will order the Pipe in small quantities as required unless some satisfactory arrangement of a general contract with quick delivery on specifications for sizes is made. We quote standard brands $13 @ $13.50 for No. 1; $12 @ $12.50 for No. 2, at tidewater. Southern Iron, same delivery, $12.75 @ $13.25 for No. 1; $11.25 @ $11.75 for No. 2; $11 @ $11.25 for No. 3; $11.25 @ $11.75 for No. 2 Soft, and $11.75 @ $12 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10 50 @ $11.

According to our Philadelphia report, sales in that market have been on about the usual scale, no larger, no smaller, but fairly in line with the offerings. The feeling is not strong by any means, and with prices ruling as they now are at the lowest ever recorded, consumers seem satisfied to cover their requirements by purchases of small lots, rather than by contracting for three or six months in advance. Consumers are determined to be on the safe side, and to that must be attributed their policy of extreme conservatism. At the same time it is obvious that consumption is not increasing to any very great extent, otherwise there would be more scarcity of Iron as well as firmer prices. Prices have shown very little change, although of late, under reports of cheaper Ores, there is less firmness than there was some time ago. Sales are chiefly in small lots, and for Philadelphia delivery at prices within the limits named below, viz.:

No. 1 Foundry	$13.00 @	$13.50
No. 2 Foundry	12.25 @	12.75

The week was a quiet one in the Chicago market in all classes of Pig Iron, with very few sales reported of over 100 tons. Inquiries for local Coke Iron are of a character indicating considerably better business in the near future. Quotations are given as follows, for cash:

Lake Superior Charcoal	$15.00 @	$15.25
Local Coke Foundry, No. 1	12.00 @	12.50
Local Coke Foundry, No. 2	11.50 @	12.00
Local Coke Foundry, No. 3	11.00 @	11.50
Local Scotch	13.00 @	13.50
Ohio Strong Softeners No. 1	13.50 @	14.50
Southern Silvery, No. 1	@	12.50
Southern Silvery, No. 2	@	11.75
Southern Coke, No. 2	11.25 @	11.50
Southern Coke, No. 3	10.75 @	11.00
Southern, No. 1, Soft	11.25 @	11.50
Southern, No. 2, Soft	10.75 @	11.00
Tennessee Charcoal, No. 1	15.50 @	16.00
Tennessee Charcoal, No. 2	15 00 @	15.25
Alabama Car Wheel	18.50 @	18.65
Jackson County Silvery	15.00 @	16.00
Other Ohio Silvery	13.00 @	13.50

The Pittsburgh market does not show any gains in volume of business, while prices continue weak and are a shade lower. It is evident that buyers have figured out a lower cost of production since the transactions in Ore took place, and are content to put off purchases until the last moment in the belief that by waiting they will be able to do better. On the other hand, Pig Iron makers claim that taking Ore, Coke, Limestone and labor at ruling prices, they cannot make Iron and realize a profit even at present prices. The tone of the market is weak, and good sized orders placed at this time would probably shade our lower quotations. We quote as follows:

No. 1 Foundry	$11.75 @	$12.00, cash
No. 2 Foundry	10.75 @	11.00 "

There has been no increase in the volume of business in Pig Iron during the week in Southern markets. There is a steady demand from the jobbing foundries in certain district, but the orders seldom reach 300 tons in any one lot, and are more frequently for single carloads, and yet in the aggregate they compare favorably with either of the several preceding weeks. The orders from the East have not been large and have been freely met. The tone of the market continues weak, and buyers with the cash in hand could doubtless buy Iron as low as it has ever been sold. There is some inquiry for Charcoal Iron at the close, but mainly at lower prices than sellers are willing to accept. Iron Pipe works are still melting more Iron than most other interests, but not as much as they have been for some time. The indications are that stocks of Southern Iron have increased during the past month, although not to any very large extent. There has been no quotable change in prices during the week, but it is evidently easy to buy at the low quotations current. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$11.00 @	$11.25
Southern Coke, No. 2	10.00 @	10.25
Southern Coke, No. 3	9.50 @	9.75
Ohio Soft Stone Coal, No. 1	14.50 @	15.50
Ohio Soft Stone Coal, No. 2	14.25 @	14.50
Lake Superior Coke, No. 1	13.00 @	13.50
Lake Superior Coke, No. 2	12.00 @	12.25
Hanging Rock Charcoal, No. 1	17.00 @	17.50
Hanging Rock Charcoal, No. 2	16.50 @	17.00
Tennessee Charcoal, No. 1	13.50 @	14.00
Tennessee Charcoal, No. 2	12.50 @	13.00
Standard Southern Car Wheel	16.75 @	17.75
Lake Superior Car Wheel and Malleable	16.50 @	17.00

Metal Market.

Pig Tin.—Straits Tin for prompt and near future delivery, in lots of 5 tons, has been sold and openly offered at 18.50¢ ℔ lb. Rumor has it that April delivery was sold at 18.25¢. Official records show that there were, at the least, offers to sell the latter at the price quoted early in the present week. The conditions leading to this result were practically the same that have depressed the market for some time past, namely, heavy accumulation of stock in Europe; liberal shipments thence to this quarter (most of which remains in bonded warehouse pending Tariff legislation); free selling to consumers by more jobbers than one at prices closely in line with actual cost from day to day, and, last but not least, the decline that took place o about £1. 10/ ℔ ton in London price during the latter part of last and the beginning of the present week. A reaction in the London market, which, on Wednesday, caused an advance of about £1 ℔ ton, served to again harden prices somewhat in the local market, making spot purchases under 18.60¢ harder to negotiate. Purely speculative business has been conspicuous by its absence in this quarter, yet the market shows a better tone at the present writing. The consumptive demand is on a more liberal scale than it has been for some weeks, and, although

hardly up to the average for the season, yet it is remarkably good considering the conditions of general trade. Jobbers' prices for small lots remain unchanged at 20½¢ @ 21¢ ℔ lb.

Copper.—Business has not improved in this quarter and there is nothing in the way of negotiations that would indicate broader interest on the part of consumers, although reports come from reliable quarters that manufacturers of various lines of Copper and Brass goods are enjoying a better trade at present than they have for some time past. Sellers, or at least some of the producers' representatives, are offering in a very indifferent way, some refusing orders that call for deliveries prior to the opening of navigation. Enough supply comes out from one source or other to meet the demand and prices are quite as soft at the present time as they were a week ago. Lake Superior Ingot has been sold at 9⅝¢ @ 9¾¢, according to brand and size of lot. Electrolytic keeps about ¼¢ less and on ordinary casting stock 9¢ @ 9¼¢ is the range. For smaller quantities from store an advance of about 1¢ ℔ lb is usually the rule.

Sheet Copper.—A somewhat better demand is noted for Cornice Copper, although orders are still of a conservative character, and apparently for little beyond the supply of actual needs. It is believed, however, that with the near approach of spring and the resumption of building operations on even a limited scale a more active movement is imminent, for stocks of material are known to be very light everywhere.

Pig Lead.—Prices have advanced a trifle and the market has gained somewhat in tone. The turn, however, does not appear to be due to any great revival in the demand in this quarter, although a few speculators have bid stifly on forward deliveries. Restricted offering is the main basis of the strength of the market. In other words, there is no pressure of stock upon the market at the present time. Hence single carloads brought 3 30¢, while bids were made of 3 25¢ @ 3 27½¢, for prompt and near future delivery, without leading to business. Consumers appear to evince but little interest in Pig Lead so far, notwithstanding its cheapness, for jobbers describe the demand as exceedingly tame. Prices for small lots are quoted at 3⅞¢ @ 4¢, with a tendency to softness at that.

Pipe and Sheet Lead.—No appreciable improvement is reported in the demand for manufactured Lead. Business remains flat, and orders and inquiries far below the average for the present season. The depression in the building trades, which is likely to continue until a revival in general trade conditions, will, it is thought, prevent any material improvement in the near future. Manufacturers meanwhile are not inclined to press their goods on the market, in view of current low prices.

Spelter.—Except of moderate quantities there have been very few sales here and the general demand is slow despite more or less "bullish" accounts received from Western points. There is complete absence of speculation or anything bordering upon it. Prices stand at 3 85¢ @ 3.95¢ for ordinary Western brands, according to time of delivery and size of order, with an advance of about ⅛¢ for small lots.

Sheet Zinc.—The consumptive demand is entirely commonplace. During the week a further reduction in manufacturers' price amounting to 3 % has caused a corresponding drop in jobbers' prices for Sheet Zinc. For 600-lb casks 4¼¢ ℔ lb is quoted, with an addition of ½¢ ℔ lb for lesser quantities from store.

Antimony.—Of jobbing parcels sales are fair, but otherwise there is little doing. Prices for small lots remain steady at about 10¢ @ 10¼¢ for Hallett's and 10½¢ @ 10¾¢ for Cookson's.

Nickel.—The market is steady, with prices ranging between 45¢ and 55¢, as to size of lot and terms.

Tin Plates.—Little change, if any, has taken place in the character of business so far as regards transactions of any size. Future business is almost entirely neglected, the larger purchasers holding off until they can see more clearly the trend of tariff legislation. Those can makers who have not already placed their orders appear disinclined to contract for future deliveries at present, while holders of stock are not anxious to push business under the present conditions of uncertainty and low prices. The market, in a word, is a waiting one. Stocks in the hands of importers and jobbers are said to be lower than they have been for many years past. Shipments from Europe for the past seven months have been very much below the average, and of the consignments received by importers it is calculated that about 60 % are held in bond pending the fate of the Wilson bill. Never has it been more difficult to secure the filling of assorted orders. To illustrate this condition, one of the heaviest importers mentioned a day or two ago that a large customer from the country had been to him with an order for seven different descriptions of Tin Plates which were urgently required. Of these, the merchant could furnish but two, and after scouring the whole circle of the trade in New York the customer was only able to obtain one of the remaining five varieties of Plates. The demand from the smaller consumers is merely of a routine nature; yet, although individual orders are generally of small proportions, they seem to be more frequently repeated, and in the aggregate show an advance over the volume of business of last month. While not heavy, however, they have sufficient weight to keep prices down to the level at which they have been for some time past.

A London cable dispatch to *The Iron Age* of March 7 reports that the London Tin Plate market has remained quiet. Buyers and sellers are awaiting developments regarding tariff legislation in the United States. Some business has been done in Oil sizes at 3½ pence below late prices, but makers are now reluctant sellers at same figures. Liverpool prices are quoted as follows:

IC Charcoal, Alloway grade	12/3 @ 12/9
IC Bessemer Steel, Coke finish	10/6 @ 11/
IC Siemens " " "	11/ @ 11/3
IC Coke, B. V. grade, 14 x 20	Nomioal.
Charcoal Terne, Dean grade	10/3 @ 10/9

Sheet Iron.—Although the leading Sheet mills are reported to be quite busy, with plenty of orders on their books, yet jobbers with one consent declare the demand for Sheet Iron to be exceedingly light, with no improvement in sight. This may probably be explained by the fact that the mills are in many instances working on heavy orders for forward deliveries placed by the larger consumers, while others have established connections with the smaller trade, whose patronage is usually given exclusively to jobbers. This is known to be the case with several Western manufacturers whose agents have been actively canvassing in Eastern districts, where the inducement of extraordinarily low prices has prevailed to secure orders. Black Iron generally is, however, moving but slowly, and prices on this material are much that purchasers choose to make them. Makers of Galvanized Sheets are not quite so anxious, it is said, to take orders for future delivery at the current rates. The advance in price of Spelter induces the hope of higher prices on Galvanized Iron in the near future. For the present, nevertheless, there is no indication of such advance, and the prices for spot material are, if anything, inclined to weakness.

We are advised that the statement that Kirkpatrick & Co., Limited, of Pittsburgh, proprietors of the Leechburg Iron Works, at Leechburg, Pa., manufacturers of fine Sheet Iron and Sheet Steel, would engage in the manufacture of Russia Patent Planished Sheet Iron, is without foundation. What gave rise to the report is the fact that within a short time Joshua S. Ingalls & Co. of Troy, Ohio, manufacturers of Craig Steel, will move their plant to Leechburg, adjacent to the plant of Kirkpatrick & Co., Limited. This removal will not necessitate any additions or extensions to the present plant of Kirkpatrick & Co., Limited, as that concern have been furnishing Steel to Joshua S. Ingalls & Co. for some years. Kirkpatrick & Co., Limited, also intend putting in two additional Tin mills and changing their cold rolling plant, but nothing more than the above is contemplated at this time, and the firm are not considering any extensive changes or improvements in their present plant.

Thomas Goddard, head of the brass foundry firm of Thomas Goddard & Son of Jersey City, N. J., died at his home, in that city, on March 7, at the age of 67.

Chicago Report.

Scrap.—Very little Old Material is moving at present. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	...
Stove Plate (free of burnt)	4.00	...
Burnt Iron and Grate Bars	3.00	...
Sheet Iron and Hoops	2.00	...
Plow Steel and Breaking Stock	4.00	...
No. 2, such as Shovels, Hoes, &c	3.00	...
Old Boilers—whole (Iron)	3.00	...
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5 ¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5⅛¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—Business has fallen off again with the advent of springlike weather. Carload lots of 12 net tons or over are nominally quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.85

MINER & PECK MFG. COMPANY of New Haven, Conn., in addition to their regular line of the Peck Drop Press, are about to place on the market a line of Friction Drop Hammers. These Hammers possess new features, the result of long experience and study of the subject.

COLBY WRINGER COMPANY, Montpelier, Vt., advise us that notwithstanding the discouraging condition of general business during the past few months their factory has not shut down and they have not been obliged to discharge any of their men. They report a very encouraging increase in the demand for their Wringers, which has been quite noticeable since the opening of the new year.

SPRINGFIELD BRASS COMPANY, Springfield, Mass., are preparing to bring out a line of Brass Drawer Pulls, finished in gilt antique and nickel. These will be made in several styles and sizes. In connection with these goods, Knobs, Hat Hooks, Toilet Screws, &c., will be put on the market soon.

CONDITION OF THE

Hardware Trade.

THERE IS A GOOD DEAL of unevenness in the demand for Hardware and kindred lines, and some manufacturers report business relatively much better than do others. There is also considerable divergence in the reports of jobbing houses in different sections of the country. Some lines of goods are still moving sluggishly, but in others there is a perceptible increase in the demand. On the whole business may be referred to as showing signs of improvement, and the trade are placing orders more frequently. The demand is beginning to set in more freely from the retailers, whose orders are more diversified than they have been. Trade, it is thought, will show a marked increase with the approach of spring, and it is hoped that a fair if not a good business may be done during the next few months. Prices do not show any increased strength, and the tone of the market is rather toward lower quotations. The quotable changes are, however, comparatively few, but concessions from regular prices are more readily obtained by close buyers.

Advices from Chicago.—The Shelf Hardware trade has experienced a notable improvement since last report. The largest houses here state that their mail on Monday was the heaviest they have received so for this year. Every day recently has shown some gain. The changed character of the demand reported last week continued to be a conspicuous feature. While the demand for Nails and other staple goods is less than it has been, the trade in small goods and in straight Hardware is improving decidedly and business is thus gradually broadening to the satisfaction of jobbers. More new stocks have recently been bought, showing that additional stores are being opened in different parts of the Northwest, where the opportunities appear to be inviting for new ventures of this character. Heavy Hardware jobbers report that their total sales for February showed a slight gain for that month over January. The condition of business is thus shown to have been somewhat better than was expected during the month. The demand at present is moderate but not strong. Wagon stock is moving considerably better, but carriage goods are neglected. Collections have not been up to the average for the last two or three weeks, but are showing signs of improvment.

Notes on Prices.

Wire Nails.—The Wire Nail market continues in excellent condition and prices are well maintained. Nearly all the manufacturers are fully occupied on orders, and some complaint is made that Naila cannot be obtained as promptly as desired. The market is represented by the quotation of $1.10 for carload lots at factory, but on especially large and attractive orders a concession of 5 cents is made. On the other hand, some manufacturers are holding Nails at $1.12½ to $1.15.

Advices from Chicago.—Manufacturers' agents report that they are not pushing their customers for specifications for Wire Nails; the mills are sufficiently busy on orders coming in to make this unnecessary. In fact, complaints are being received from merchants who have contracts with the Wire Nail factories in this locality that they are not receiving shipments fast enough. One mill is known to be at least a month behind in its deliveries. Inquiries have fallen off, but there are some large buyers who would take in additional quantities at old rates if they were able to induce manufacturers to accept such terms. The jobbing trade is inclined to quietness, but that is because the retailers are now stocked and waiting for the demand for those who drive the Nails. The advent of spring weather is expected to cause a rapid growth in this demand in the course of the next week or two. A decided increase in business is reported by manufacturers of Wire Tacks, who have been meeting with great success in the introduction of such Tacks to the favor of the trade. Prices on factory lots of standard Wire Nails are continued at $1.20, Chicago, while small lots from stock are selling at $1.25.

Cut Nails.—The Cut Nail market has not developed any specially new features, the condition being substantially as for the past few weeks, with perhaps a slight weakening in the tone of the market. Manufacturers in the East are still adhering to their policy of quoting only prices for Nails delivered, and are naming $1.05 for carload lots, on dock, New York, but it is rumored that this figure has been shaded. The price from store in New York is steady at $1.15.

Advices from Chicago.—The volume of business in Cut Steel Naila is gradually growing larger. The manufacturers report continued sales in directions in which Wire Nails had until recently almost taken absolute control of the trade. This is true not only of the city trade, but also of localities in the country in which sales of Cut Nails had for some time fallen to very small proportions. The jobbers who have placed good sized contracts are sending in specifications promptly, showing that Naila are needed to supply the wants of the trade. Quotations on factory lots are unchanged at $1.05, Chicago, for 60-cent average. Small lots from stock are selling at $1.15 to $1.20.

Barb Wire.—The Barb Wire market is steady, with a good volume of business. Quotations for carload lots of Four-Point Galvanized are as follows: Pittsburgh, $2.15; Cleveland, $2 20; Cincinnati or Allentown, $2.25; Chicago or New York, $2.35. An ad-

vance of 5 cents per 100 pounds is made on carload lots.

Advices from Chicago.—The Barb Wire manufacturers are now engaged in the pleasant work of staving off deliveries, as they seem to be sold so far ahead that their customers are generally complaining about the non-appearance of goods in time promised. Some large buyers are endeavoring to secure shipments which were promised in April, claiming that they need a very much larger quantity than they had anticipated when they placed their orders. Small lots of Galvanized Barb Wire are quoted at $2.40, and carload lots at $2.30.

Household Specialties.—The following are the prices announced by Silver & Co., 304 to 310 Hewes street, Brooklyn, and 20 Warren street, New York, on their line of kitchen furnishing goods and household inventions, as shown in their catalogue of February, 1894. The jobbing prices announced are only given in consideration of an order for at leaat three dozen of a kind. Terms, f.o.b. New York and Brooklyn, cash in 30 days, with 2 per cent. discount for cash in 10 days:

41	98 " 100	60	14.50

Referring to the change in prices on these goods, the manufacturers remark, in a circular letter to the trade, that they consider it best to use a high list and a large discount in order that dealers may be given an opportunity of realizing more margin of profit than by using a low list and small discount.

Glass.—The first week in March has not witnessed any strengthening in Glass prices, although some improvement is noticed in demand. It is reported that there has been a decrease in the productive capacity of the country during the past week, equivalent to 24 pots. Many of the factories which have gone out of operation have no stock of Glass on band and are dependent upon those in operation to fill immediate orders. Other factories are quoting Glass for delivery up to July 1, which is the regular time for closing all factories for the summer. Pittsburgh quotations remain unchanged at 85 and 10 and 5 per cent. discount for single and 85 and 20 and 5 for double strength Glass. It is understood that single strength Glass has been quoted at 85 and 10 and 7½; and that for immediate shipment 88 and 89 per cent. discount has been quoted for single and 90 per cent. discount for double strength. New York prices for French Window Glass are represented by a discount of 80 to 80 and 20 per cent. discount, and French Plate by 75 and 10 and 5 per cent. discount.

Old Metals.—The market for Old Metals continues dull, with prices at the lowest notch. There is, however, a little more movement in certain descriptions of Scrap Iron, and the stock in dealers' hands does not appear to be increasing; therefore, it is believed that prices can hardly go much lower. The following quotations represent about the prices paid by dealers delivered in New York:

Heavy Copper.....	℔ lb 7¢
Light and Tinned Copper.....	℔ lb 6¢
Heavy Brass.....	℔ lb 5¢
Light Brass.....	℔ lb 4¢

White Wringer Rolls, ℔ lb.	@	.04¼	
White Syringes, ℔ lb.....	@	.05	

Trade Notes.

AN INTERESTING ASSORTMENT of Tinware is noted in the advertisement of the Geuder & Paeschke Mfg. Company, St. Paul avenue and Fifteenth street, Milwaukee, Wis. Cream Cans, Dairy Pails and Watering Pots of different sorts are referred to.

AN ADVERTISEMENT on another page of I. W. Numan, 104 East Fourth street, Canton, Ohio, directs attention to Numan's New Fruit Tree Sprayer with extension for high spraying. An illustration shows the application of the device.

IN REFERRING, in *The Metal Worker* of March 3, to a circular that had been issued by Francis I. Maule of Philadelphia, a typographical error appeared in the address. Mr. Maule is located at Room 40, 328 Chestnut street, Philadelphia.

THE ANNOUNCEMENT ELSEWHERE of the J. H. McLain Company, Canton, Ohio, with offices at Boston, New York, Chicago and San Francisco, directs attention to the Humber Hot Water Heaters, which are made in 20 sizes for hard or soft coal.

THE FERRACUTE MACHINE COMPANY, Bridgeton, N. J, manufacturers of Presses and Dies, report that business is improving and that they are receiving orders for their new styles of Presses, which were exhibited at the Chicago fair, some of them having proved especially popular. Among others they are building a new style of adjustable bed combination Press which can be used for horning, seaming, wiring, curling, cutting and forming. It is very convenient and a great improvement on other Presses of this kind now on the market. They have recently issued a small catalogue illustrating their various styles of Presses. They manufacture over 300 different kinds of Presses, all kinds of Dies and many other sheet metal tools.

COLBY WRINGER COMPANY, Montpelier, Vt., have made arrangements with Surpless, Dunn & Alder, 97 Chambers street, New York, by which the latter will represent them directly to the trade throughout the country.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

M. V. WOODWARD has just received the contract for plumbing and steam heating the new residence of Capt. B. F. Peet, near the lower wharf, Southport, Conn.

BIDS will be received up to March 15 for a system of hot air heating and ventilation and sanitary dry closets for a 16-room school building by the Board of Education of McKeesport, Pa.

DAVIS & JOHNSON will erect at Oak Park, Chicago, at a cost of $12,000, a two-story flat building to have furnace heat and a system of plumbing.

BIDS will be received up to March 31, at the office of Joseph Leicht, Winona, Mich., for a steam heating plant for the Philharmonic Society Building. Bids will also be received for a fan system. Guarantee will be required to heat the building to 70° with the outside temperature at 30° below zero. Not less than 1 square foot of radiating surface must be provided for 30 cubic feet of space.

J. W. GREENWOLD has been awarded the plumbing contract at $4300 for the National Union Building, at Toledo, Ohio.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until March 27 for the interior work, plumbing, &c., of the United States Post Office building at Fort Dodge, Iowa. Drawings and specifications may be obtained from the office of the Supervising Architect, Washington, or can be had from the superintendent at Fort Dodge.

THE STEAM HEATING PLANT installed in the Eighth Precinct Station House and police headquarters, on Macdougal street, near Spring street, New York, has been formally accepted. The work was done by Higgins & Co., 379 Lexington avenue, who use a Richmond Sectional steam boiler.

THE D. F. MORGAN BOILER COMPANY, 23-25 West Lake street, Chicago, have the contract for steam heating in the apartment building of Trebilcock & Penhalligan, Stewart avenue, near Sixty-fourth street.

WALLACE & MCNAMARA, Des Moines, Iowa, have secured the contract for the steam heating in the Lutheran College, Jewell Junction, Iowa. An American boiler will be used.

KEHM & MERTZ, steam heating contractors, 289 East Kinzie street, Chicago, are to furnish the boilers and steam heating plant for the Gormully & Jeffery Mfg. Company's addition to their bicycle factory, at Pearson and Franklin streets.

T. B. CRYER & Co., Newark, N. J., recently installed a No. 26 Perfect hot water apparatus in the residence of Bank President Elliott, at Goshen, N. Y. There were 800 feet of radiation, and the system contained about 400 gallons of water, and in 15 minutes after the fire was lighted warm water was being returned to the boiler.

THE MOORE HOTEL, at Shelby, Mich., has been purchased by D. S. Rankin and A. G. Avery, who will remodel it and put in a steam heating plant.

RUFE BROS. have received the contract for an extensive steam heating outfit for a new hall, 100 x 50 feet, and three stories high, just built by the Harmonia Singing Society at Chester, Pa.

DANIEL ROCK, 86 North Clark street, Chicago, has the contract for the plumbing, sewerage and gas fitting in the residence of M Reissnider, Lake View.

It Is Reported—

THAT W. J. Knowles and W. G. Nott have dissolved their partnership in the Hardware business at Brantford, Ont., Mr. Knowles retiring to devote his entire time to the management of the Goold Bicycle Company and the Knowles, Ham & Nott Company. He has been succeeded by Walter R. Turnbull, the name of the new firm being Nott & Turnbull. Mr. Turnbull has been connected with J. Y. Morton & Co. for the past six years. Mr. Nott has been identified with the business for over seven years. Improvements are contemplated in the present premises. Among other things they will have a plate glass front. The establishment will also be materially enlarged.

That McClellan & Sons Hardware store, at Troy, Kan., was badly damaged by fire on the 16th ult.

That the Hardware store of Keefer Bros., Olathe, Kan., was broken into by burglars on the 14th ult., and seven double barrel Shot Guns and one Repeating Rifle, worth over $200, were stolen. Entrance was effected by cutting through a large plate glass window in front.

That the Jones Hardware Company have been organized at Richmond, Ind. The capital stock of the company is $25,000. The directors are Sharon E. Jones, Clement W. Carr and James W. Carr.

That the Hardware store of Albrecht Bros., Wahpeton, N. D., suffered damage by fire to the extent of $5000 on the 15th ult.

That the Hardware store of O. A Martin, Fox Station, Ind., was burglarized of $25 worth of Revolvers on the 11th ult.

That Millspaugh & Drake's Hardware store, at Corning, N. Y., was damaged by fire and water on the 14th ult. The loss is fully covered by insurance.

That Peterson & Boyson, Hardware dealers, Lyle, Minn., have dissolved partnership. H. N. Peterson will continue the business alone.

That John F. Peck of Gardner, Ill., will open a new Hardware store at Virginia, Ill.

That on the 15th ult. burglars raided the Hardware store of L. B Shapland, Guthrie, O. T., and got away with a large quantity of Guns, Ammunition and Revolvers.

That the Crary Hardware & Stove Company, as successors to Crary & Parsons, have been organized at Delevan, Wis. The incorporators are Henry G. Hollister, E. M. Crary, H. C. Hollister and Charles L. Crary. The officers are H. G. Hollister, president; E. M. Crary, secretary, and Chas. L. Crary, manager.

That F. L. Thompson and J. M. Lewis have purchased the Hardware stock of the late J. T. Cadby, Muscoda, Wis., and have formed a partnership to carry on the business.

That the style of the Hardware firm of G. W. Anderson & Co., Griswold, Iowa, has been changed, and the firm will hereafter be known as J. L. Anderson & Son.

That E. A. Stephenson, Lowell, Iowa, is erecting an addition to his Hardware store, and will place in it a line of Farm Implements and Farm Machinery.

That the Hardware business at Omro, Wis., formerly the property of Fred. Bunker, but recently in the possession of S. J. Seabury, has again changed hands, the purchasers being Imig & McNulty of Waukesha, who will hereafter conduct the store.

That A. L. Richardson of Van Wert, Iowa, has purchased a Hardware store at Promise City.

That E. M. Allen, Hardware merchant, Hastings, Neb., has disposed of his stock of goods to William Ohlheiser.

That the Hardware firm of H. W. Crane & Co., Mt. Pleasant, Iowa, have sold out to a new firm under the style of T. A. Niece & Co.

That by a fire on the 21st ult., Richards Bros., Hardware dealers, East Tawas, Mich., lost $12,000.

That the Palmer Hardware Company, Rockford, Ill., have greatly enlarged their establishment, having leased the store adjoining it.

That the Hardware store of Justus, Rogers & Co., Bluffton, Ind., was burglarized on the 17th ult.

That Chas. Brent, Smithshire, Ill., has sold his stock of Hardware to M. S. Yoho of Ellison.

That about March 1 A. N. Bucklin & Co., Grand Junction, Col., will remove their Hardware stock into larger quarters.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

HELP WANTED.

At once, a TINNER who understands retinning old tinware. Louis Dyer, 44 Dekalb avenue, Brooklyn, N. Y. Mar. 10

A FOREMAN for a wood pattern shop for stoves; must be a first-class draftsman and designer; references required. "D. and D.," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 10

SALESMEN to carry our specialties, &c., on commission as a side line in Pennsylvania, Ohio, and the New England States. Clifton Springs Mfg. Company, Clifton Springs, N. Y. Mar. 10

At once, a STOVE PATTERN MAKER; one that is experienced in making wood patterns for stoves; state wages and give references. A. J. Lindemann & Hoverson Company, Milwaukee, Wis. Mar. 10

A first-class TINSMITH who can invest $500, to manufacture milk coolers; write at once to H. W. Gazlay, Cortland, N. Y. Mar. 10

A first-class PLUMBER, STEAM and GAS FITTER; one having a fair knowledge of tin and furnace work; must be temperate. Address, with stamp, "Plumber and Tinner," 513 Central avenue, Fort Dodge, Ind. Mar. 10

TIN LITHOGRAPHY; a man who is an artist and engraver; submit samples if possible; state experience and wages expected. The McClary Mfg. Company, London, Ontario. Mar. 10

SALESMAN to handle as side line on commission Dockash line of stoves and ranges; Illinois, Southern Iowa, Nebraska, Missouri. Judson A. Tolman, 28, 30 and 32 Van Buren street, Chicago, Ill. Mar. 10

Enterprising parties to handle on commission a greatly improved patent ventilator for roofs, chimneys and vent pipes. "P. A. C. Co.," room 12, 18 South Broad street, Philadelphia, Pa Mar. 3

A good boy between 16 and 18 years of age to learn the tinning and plumbing trades, one who will serve for three years and board with employer. A. M. Kreider, Lititz, Pa. Mar. 3

A first-class man who understands TIN and SHEET IRON WORK, PLUMBING, IRON PIPE WORK and GENERAL JOBBING; steady work to the right man; must be steady and sober; state experience, age and salary. Brown Bros., Lebanon, N. H. Mar. 3

A practical STOVE PATTERN FITTER; sober; must be well recommended. "Superintendent," Box 33, office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 3

A young married man, 25 to 30 years old, who has had experience in bookkeeping and buying in a large cornice and tin jobbing works, or has experience in a wholesale and retail tinners' supply house; must be a good penman, quick and accurate at figures; state all places where formerly employed, how long in each place, cause of leaving and duties performed; best of references and bond required; state salary expected; answer above questions fully or no communications will be considered. "Bookkeeper & Buyer," office of *The Metal Worker*, Bank of Commerce Building, St. Louis, Mo. Mar. 3

SITUATIONS WANTED.

HEATING and VENTILATING ENGINEER wishes to make a change; has had seven years' experience in warm air heating and ventilating, and can sell, estimate and superintend installation of work; best of references, and can carry a trade with him; moderate salary and steady position desired. J. H. Giles, Elmira, N. Y. Mar. 10

By the year, with first-class hardware house; advertiser is married, steady and sober; 17 years' experience in tin, copper and sheet metal business; first-class cornice cutter; willing to work in Missouri, Arkansas or Texas, the latter State preferred. J. F. Rucker, Rosebud, Texas. Mar. 10

By practical TINSMITH at all branches of the tin and sheet iron trade, furnace, stove, fire place heater, tin roofing, pump and iron pipe work and general jobbing; married; temperate. E. G. Braumgard, 312 Van Buren street, Chicago. Mar. 10

Steady work, by a first-class PLUMBER. J. Becker, 235 East Ninety-fourth street, New York City. Mar. 10

By a first-class PLUMBER. J. P. Hayes, 1660 Third avenue, New York City. Mar. 10

By an experienced TINSMITH. E. Gold, 62 Boerum street, Brooklyn, N. Y. Mar. 10

By a first-class PLUMBER and STEAM FITTER; some knowledge of tin and sheet iron work; city or country; references; tools. W. F. Farrell, Box 276, Mt. Carmel, Pa. Mar. 10

By a first-class PLUMBER; in country or city. George Foley, 267 Wyckoff street, Brooklyn, N. Y. Mar. 10

By an A1 practical PLUMBER, in city or country; first-class wages. Richard Riely, 36 Verandah place, Brooklyn, N. Y. Mar. 10

By a first-class PLUMBER, in the country; first-class wages. Joseph Kelly, 1103 Third avenue, New York City. Mar. 10

By a first-class man at plumbing, hot water and steam heating, furnace and blow pipe work, and all kinds of tin and sheet iron work; can set tile and do brick work of brick set furnaces and boilers; estimate from plans; held position as foreman for years; good references. H. George, care of Schwarts, 561 Broadway, Brooklyn, E. D., N. Y. Mar. 10

Experienced MANAGER and SUPERINTENDENT desires situation; understands modern methods of economical manufacture, designing and constructing metal patterns, cast and malleable iron foundry work, steam and hot water heating; specialty: goods pertaining to the steam and gas pipe trade; unexceptionable references. "R," office of *The Metal Worker*, 220 South Fourth street, Philadelphia, Pa. Mar. 10

By a steady, reliable man, 34 years of age, who understands all kinds of heavy sheet iron work, boiler making and tank building; can lay out work, and fit up, &c. R. Campbell, 16 Oak street, Kearney, N. J. Mar. 10

As FOUNDRY FOREMAN; understands making pipe fittings; can get up plates and drop patterns for making castings; good references. "W. H. G.," 137 State street, Sing Sing, N. Y. Mar. 10

By a competent man, as CUTTER on metal cornice work; first-class bench workman; best of references. "H.," No 310, office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 10

By a man with nine years' experience at furnace work and general jobbing; would also go as clerk; German; city or country. W. F. Gritzmocker, Le Sueur, Minn. Mar. 10

By a TINNER with four years' experience at general line of tin work, roofing and spouting and some knowledge of furnace work; single, steady and temperate; would like a steady job; references furnished. Percy W. Pyfer, Forreston, Ill. Mar. 10

By a practical TINSMITH, capable of doing tin and sheet iron work, roofing and general jobbing; 18 years' experience; city or country. H. Gold, 92 Essex street, New York City. Mar. 10

As TINNER; have had 12 years' experience at inside and outside general job work and tinware, also pump and pipe work; 28 years old and single; small city preferred. "Y. Z.," care of Chas. Dellman, 602 East Sixth avenue, Pine Bluff, Ark. Mar. 10

By a ROUGE BUFFER, eight years' experience with the Meriden Britannia Company of Meriden, Conn., on knives, forks, spoons, &c.; also one year's experience on hollow ware and light nickel for Gaitley of Troy, N. Y. Edward W. Hoag, Old Chatham, N. Y. Mar. 10

By a PLUMBER; steady; willing to go to any part of the country. J. Fitzpatrick, 229 Broadway, New York City. Mar. 10

BRASS MOLDER or WORKING FOREMAN, by a steady man of large experience in the mixing and melting of metals for any class of work, heavy or light; location no object; good references. "H. A. H.," 36 Sampson street, Allegheny, Pa. Mar. 10

An experienced stove man wants to handle a line of stoves, ranges and hollow ware; salary or commission. "R. L. S.," South Bend, Ind. Mar. 10

By a young man 26 years of age, with 13 years' experience on French cooking ranges; good sheet iron worker. J. E. Dupont, 227 South Waters street, Sheboygan, Wis. Mar. 10

By a TINSMITH and PLUMBER; 16 years' experience at all branches of the trades; German; steady and sober; married; country preferred. "Tinner," care of cigar store, 339 East Twenty-second street, New York City. Mar. 10

By a TINSMITH who thoroughly understands his trade; 16 years' experience at roofing, spouting, furnace, pump and pipe work and plumbing; country preferred; good references as to ability. G. Rourke, 925 Pacific street, Brooklyn, N. Y. Mar. 10

Steady situation desired by a first-class TIN and SHEET IRON WORKER; good references. Max Naumann, 300 East 104th street, New York City. Mar. 10

As CUTTER and FOREMAN, by a first-class cornice and skylight maker; thoroughly posted in all the details; steady and sober and not afraid of work; can give best of references; New York or Brooklyn preferred. "W.," Box 2, 261 Atlantic avenue, Brooklyn, N. Y. Mar. 10

By a SANITARY PLUMBER; married; strictly temperate; wants a position in any part of the United States; can work both iron and lead; good references. C. Spencer, 185 Seymour street, Auburn, N. Y. Mar. 10

By a TRAVELING SALESMAN; stove line, gas stoves or a specialty preferred; well acquainted all over east of Mississippi River; references strictly A1; salary very reasonable. R. Williams, with the Wolff Gas Radiator Mfg. Company, 164 Franklin street, New York City. Mar. 10

By a first-class PLUMBER; willing to work in city or country; can furnish excellent references; 11 years' experience. Frank Miller, 124 Boulevard, New York City. Mar. 10

By a first-class PLUMBER; city or country; best of references; 13 years' experience. GEO. A. Blessing, 2359 Eighth avenue, New York City. Mar. 10

By a TIN and SHEET IRON WORKER; 14 years' experience; understands roofing, pump and furnace work and general jobbing; can make up tinware; country preferred. J. Moble, 35 Swan street, Trenton, N. J. Mar. 10

By a PLUMBER who understands hot water fitting; willing to go East, West or South; a growing town preferred; sober; good references furnished; state wages. "A. B. C.," care John Flynn, 331 West Seventeenth street, New York City. Mar. 10

By a TINNER; five years' experience at outside work and general jobbing; also good at furnace work and iron piping. "Tinner," Box 58, Madison, N. J. Mar. 10

By a young man 30 years of age, as CLERK in retail hardware store or good position in a wholesale hardware house; practical TINSMITH; 15 years' experience in the hardware business, both city and country; willing to go as traveling salesman; good references. P. O. Box 82, Westfield, Pa. Mar. 10

As TINSMITH, ROOFER and GENERAL JOBBER; city or country. John Klein, 616 Fulton street, Elizabeth, N. J. Mar. 10

As TRAVELING SALESMAN for bicycles or sporting goods of any kind; understands the repairing of wheels, &c.; two years' experience on the road; A1 references. "J. H. F.," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 10

With stove foundry or manufacturing concern: have held positions in large concerns as superintendent of manufacturing department, also as steam and hot water heating engineer, and as correspondent and advertising man; capable of taking charge of either branch; will make satisfactory terms if prospects are fair. "D.," Box 2, 142 East Forty-eighth street, New York. Mar. 10

By cornice cutter and draftsman, as CUTTER or FOREMAN; am first-class mechanic at all kinds of sheet metal work; first-class reference given. T. A. Hughes, 132 Seventh street, N. E., Washington, D. C. Mar. 10

Steady position desired by a young married man; five years' experience as clerk in hardware store; eight years at tinning, roofing and general jobbing; best of references. "E.," P. O. Box 176, Middletown, Pa. Mar. 10

Steady work, or as long as possible, by a thoroughly practical TINNER; one who understands and can do all kinds of outside and inside work, such as roofing, cornice, repairing, general jobbing, stoves, tinware, &c; sober; unmarried, and energetic; good references. J. S. Burch, Vesta, Tenn. Mar. 10

By a sober, industrious MECHANIC, who can do tin, sheet iron, furnace and cornice work, estimate from plans and lay out patterns; willing to go on trial two weeks at reasonable wages. "J. L.," 128 Jacunda street, Pittsburgh, Pa. Mar 10

By a first-class practical CORNICE CUTTER, as foreman or cutter. Thomas McNamara, 28 Devoe street, Brooklyn, N. Y. Mar. 10

Steady position, by a young man capable of doing all work done in a practical tin shop; good references; single. Frank A. Fleck, Middletown, Pa. Mar. 10

As TINSMITH, by a young man of good habits, steady and reliable; can do tin, slate or iron roofing, pieced work and general jobbing; have been employed by a large cotton mill as tinsmith for nearly two years; five years at the business. C. J. Hinman, Bainbridge, N. Y. Mar. 10

By a young man with nine years' experience in hardware business, both on road and in house; moderate salary; best of references as to character and business capacity. "Cutlery," Box 106, Canton, Miss. Mar. 10

With some good, reliable firm as TINNER; can do anything around a tin shop; temperate man; can give references. W. L. Mallory, 106 Orchard Court, Akron, Ohio. Mar. 10

By a TINSMITH; experienced at pump work and general jobbing; can act as salesman; furnish a set of tools. "Leack," Box 72, Springfield, Vt. Mar. 10

By a MECHANICAL DRAFTSMAN who thoroughly understands heating and ventilating in all its branches; strictly temperate and reliable. J. P. Lisk, 636 Meserole street, Brooklyn, N. Y. Mar. 10

The 36-Box Rule in Wales.

The action of the Welsh tin platers' union in clamorously insisting on the strict enforcement of the "36-box rule" in all the tin plate works appears to be a most injudicious move at the present time, when so many works are idle and so much distress prevails among the workmen in this industry. The only outcome of the agitation, so far, has been the closing of further mills, whose owners either object to being dictated to by the union officers, or who cannot afford to restrict their product. Several owners of tin plate works have lately furnished them with improved machinery for the express purpose of increasing their output, and it is only by getting the utmost use out of these improvements that they can hope to reap any profit at all in the present condition of the tin plate market. If the Welsh tin platers wish to play into the hands of American manufacturers they could not adopt a more effective course for hampering and damaging their own trade. The movement of the tin plater's union is certainly ill-timed, and is far from likely to benefit the workmen for whose behalf the union is ostensibly acting. Where manufacturers can make a reasonable profit from an output of 40 or 45 boxes a day per mill —easily obtained with the present improved machinery—but cannot do so if the output is to be restricted to 36 boxes, it is not likely that such a rule will be adopted. It is cheaper to shut down and wait for better times. In this case the workmen are the greatest sufferers.

The Building Outlook.

One of the most cheerful prospects in the trade situation is in the direction of building operations. Seldom has the future looked brighter for those in the building trades than at this time. There were indications of this some time since, when architects' offices were reported to be again filling up with work. But what was then to some extent a matter of mere promise now seems actually nearing fulfillment. Building permits are being taken out in large numbers in the leading cities, and contracts are getting into the hands of builders. In the city of Chicago the records for the month of February show building permits granted for almost as great a frontage and nearly as high a total value as in February of last year. This is particularly significant from the fact that in the spring of 1893 building was very active in that city among those who were making preparations for the World's Fair. Few cities at that time were as busy in the building line as Chicago. If preparations for building there are now on a scale but little below that of last year, it augurs well for a very important branch of trade on which many other branches depend.

Moderation in Building.

The character of the permits now being taken out in the cities shows quite a change. Fewer great structures are in prospect, but the great bulk of the buildings projected are houses of moderate size, good store buildings and a sprinkling of warehouses and factories. Builders will consequently be more generally employed by the greater number of separate contracts, and the ordinary mechanic is likely to find employment of a more steady character than when great structures are being rushed to completion as speedily as possible. There has probably not been so favorable a season for making improvements of this character for 20 years. All kinds of materials are lower than ever before known in this country. Builders are anxious to obtain work, and, generally speaking, workingmen are even more anxious to get to work because many of them have had nothing to do for a long time and have either exhausted their resources or soon will do so if they do not speedily find employment.

Heating Surface of Boilers.

If anything in steam engineering may be said to have been positively determined, it is the fact that the same extent of heating surface in different types of boilers does not have the same efficiency; and that the relation of grate area to heating surface ought to vary, not directly as the extent of the heating surface, but directly as the total efficiency of the surface. A boiler whose heating surface of, say, 100 square feet has a maximum evaporative power of 300 pounds of water per hour wants no more grate than another one having a surface of 75 or 80 feet so placed that its total evaporative capacity is the same as that of the first. Every square foot of grate more than enough to supply heat for the maximum evaporative capacity of a boiler is a square foot of error in its construction in the direction of fuel waste. It is true that convenience in the use of heating boilers demands that their grates shall carry a sufficient amount of fuel to obviate the necessity of too frequent supply. Such capacity, however, should be obtained by ample depth of fire box rather than by excessive area of grates.

New Boiler Designs.

The birth rate of new heating boilers in this country is, at present, about one a week. An examination of the new comers, as well as many that are not new, shows that in many of them no provision has been made for the adjustment of the grate area to the evaporative efficiency of the surface transferring the heat generated to the contained water. It is likely that tests of a large number of them would show in some a deficiency and in others an excess of grate as compared with evaporative capacity of heating surface. In most boilers designed purely for heating work, the heating surface is of such complicated form—that is to say, has such peculiar shapes and positions in its various parts—that any attempt to calculate evaporative capacity in advance of trial will nearly always fail. The only reliable determination in such cases is through actual test; and if this can not be done with different great areas, how can it be ascertained whether a boiler has worked in the test up to its maximum of both efficiency and fuel economy? Is economy an unimportant consideration in a heating boiler? If it be so regarded by any designer of new boilers he will find, in competing with established manufacturers, that he is making no longer a square foot of error, but a square acre of indiscretion.

A comparative summary of the exports and imports of merchandise during the seven months ending January 31, 1893 and 1894, recently published, shows that imports into the United States fell off during the latter half of last year to the extent of $112,822,621, as compared with the period ending January 31, 1893, while exports increased by $41,264,227. The figures are:

Imports.

Seven months ending January 31, 1893	$484,371,681
Seven months ending January 31, 1894	371,549,060

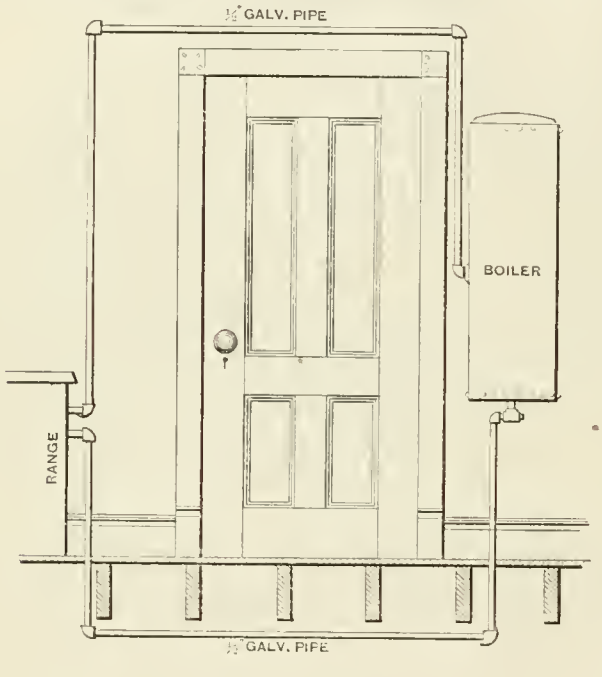
Exports.

Seven months ending January 31, 1893	$519,031,818
Seven months ending January 31, 1 94	560,295,54

THE LETTER BOX.

Small Air Bound Pipes.

From E. J. S., *Ramapo, N. Y.*—In *The Metal Worker* of February 10 I noticed the letter and answer headed "What Caused the Collapse?" and found it very interesting, and as I experienced the rumbling noise described as having preceded the collapse of the copper range boiler I will lay my case before your readers also with an illustration of it. My tank is 10 feet higher than the boiler, but the rumbling noise is at times very disagreeable and can



Small Air Bound Pipes.

be heard all over the house, sounding like the noise produced by turning steam under heavy pressure in a vessel of water, as is done in manufacturing establishments for heating water. I have observed that with a very hot fire in the range the noise in the boiler is louder and continues longer than at other times. It generally occurs when water is being drawn from a faucet somewhere in the house, and it makes no difference whether hot or cold water is being drawn. Sometimes, however, it will occur when the fire is quite low and no water is being drawn. The noise almost always is produced by feeding water into the heater in the cellar, which is connected to the same pipe that supplies the boiler. I will describe the system of piping, and will invite your readers to criticise. I am in hope that a solution of the problem will be found by altering the pipe system. I will say beforehand in explanation that owing to the fact that there is no plumber near by I superintended and directed the piping myself, and therefore the system may be quite objectionable in the eyes of the practical plumber. The boiler is of 40 gallons capacity, stands about 5 feet from the range, and the pipe which supplies it drops from tank on second floor to the cellar, and from thence rises up through the floor to the top of the boiler and extends down to near the bottom, as shown. The pipe from the boiler to the water back drops down to the floor and across to the range, where it rises up through the floor and connects to the lower connection of the water back. The pipe from the water back returning the hot water to the boiler rises from the water back up to a hight a few inches above the top of the boiler and then crosses over and drops down into the proper connection in the side of the boiler. The peculiar method of piping this return to the boiler was necessitated by having to run it high enough so that a closet door would swing under it. All the pipe is ½ inch galvanized iron, measuring about ⅝ inch inside. The illustration shows the arrangement with the exception of the supply pipes and hot water service pipe.

Note.—We hope our readers will accept the invitation to give their views in this case. In the meantime, we would suggest that the use of larger pipe would give a freer and smoother circulation. The small pipe does not allow the water to circulate with sufficient rapidity to prevent it becoming overheated in the water back; consequently steam is generated and causes the noise mentioned. The pipe running over the closet door, dropping down to the boiler, is another cause for the noise. If steam is condensed in the pipe it would naturally jar all the pipe in the system, and the rush of water in filling the vacuum produced would also make a shock and noise. We would suggest as a remedy that the boiler be raised up, so that the pipe will run directly into the side opening without any dropping down. If this is not possible, the side opening could be plugged and an opening made in the boiler higher up, or if this is impracticable, the return pipe from the water back can be connected with the hot water service pipe at the top of the boiler. The rise in the pipe as it passes across the top of the door having no vent permits the collection of air, which would impede the circulation. The slight pressure in the system, from the tank being so little above the boiler, facilitates the generation of steam, and when water is drawn at any of the faucets in the house the pressure is further reduced, which for the time being aids the generation of steam and increases the noise. Where the pressure is slight it is always well to have larger pipes to and from the water back, even to 1 inch in capacity, to provide for a free circulation, so that no water will remain in the water back for a sufficient time to be heated to the boiling point. The ell at the water back must necessarily be a reducing ell from 1 to ½ inch, and by changing the return pipe to the boiler to 1 inch in size in all probability the trouble reported will be very much relieved, if not remedied.

Work and Wages.

From H., *Michigan.*—In your issue of February 24 I see a letter from "Right Hand," referring to left hand tinners. I once worked with one and I could not see any difference between his work and a right hand man of the same ability. To me it seems an absurd idea that a left hand man cannot make as good a mechanic as the man who some would term his more fortunate brother, because he has been born with strength and handicraft predominating in his right arm. When I used to be putting up more gutter than falls to my lot of late years I never considered it a smart trick to either solder or hammer with my left hand, if I was in a tight place on a ladder or elsewhere. But to make the subject more interesting, let me state what I find a greater drawback than left handed men. It is the impractical and uneducated men who pose as mechanics, and a great many employers are more to blame than the men. Why? Because the employer looks too often at the wage per day he is paying, but does not follow it up with a close examination of the amount of work he is getting for said wages. To illustrate: Last fall a man was engaged to help on some contract work. He was placed on the same building as another man, a steady hand, who worked steady but not hard. When the day was done the new man had done, with no exaggeration, twice as much work as the old one. The old hand had spent a big

part of the time looking round, talking, &c. When pay night came the new hand wanted 25 cents per hour. He was paid, but could not be kept on, as the price was too high. The old hand got 20 cents per hour. Which was the cheapest man? It does not need a mathematician to answer that question. But please answer the following: What are we going to profit by spending time and money educating ourselves and becoming proficient in the trade (by proficient I mean a man who can estimate for and perform a work anywhere from a cornice or furnace job down to a tin cup), when an inferior man may command as good wages, with few exceptions? I have also worked in shops where the foreman would have very little use for a man who would not take a certain degree of interest in unloading beer schooners.

This is a subject I could write more largely upon if space would permit, but would like to see the matter agitated and hear from a number of *Metal Worker* readers.

Left Handed Tinners.

From J. Van P., *Sac City, Iowa.*—In *The Metal Worker* of February 24 I notice a communication signed "Right Hand" of Pennsylvania, in which he gives his experience (which has not been large) and invites readers of the Letter Box to do the same in regard to left handed tinners. As I am one of the (in his estimation) unfortunate ones under consideration, I will very cheerfully give my experience, which extends over a good many years and a good deal of tinners' work in New York, my native, and in Iowa, my adopted State. In all that varied experience in both States the fact of my being a left handed man has never been any disadvantage, but, on the contrary, has often been a convenience when working on awkward shaped tin roofs and soldering around corners. I think "Right Hand" must not be as observing as the school children of his town or he would not have suggested left handed tools, for what shape could the handle of soldering copper, hammer and mallet be to accommodate a left hand? And did he ever observe that all the stakes are straight handled and couldn't very well be any other shape, and how would squaring shears be arranged to be convenient to left hands? And the bench shears. I would call his attention to the fact that they are exactly like left handed snips, are they not? I mean in their manner of cutting. And still another fact has no doubt escaped his observation. I would ask which hand of a right handed man does the most in working the machines in tin shops turned with a crank. Is it not the left hand? The right one merely turns the crank. A left handed fire pot would be as sensible to suggest as any other tool that tinners use.

From W. C. H., *East Haddam, Conn.*—Referring to recent articles in *The Metal Worker* on "Left Handed Tinners," it fell to my lot to learn the trade from a left handed man. My father being a tinner used to take me with him as soon as I was large enough to be of any use to him, and for 15 years I have been steadily in business with him. I have never noticed that my father's left hand was any detriment to him. He even claims that he can do work that a right handed man cannot, being able to use both hands in tight places. I do not have much sympathy with your correspondent in *The Metal Worker* of March 3, who was sorry for his bargain with the left handed boy, as his own experience taught him evidently that lefthandedness is not necessarily a mark of inefficiency. The trouble with the fellow who could not "pipe the house" must have been in his head, as that story hardly seems compatible with ordinary intelligence, supposing him to have been in the shop for any length of time. I do not remember having suffered any inconvenience in receiving instruction from my father on account of his left hand, except to reverse the order of holding a tool at work, which readily adapted itself to my intuition. We have but one left handed tool in the shop, which is a pair of snips and which for convenience I would rather use than a right hand pair. My advice would be to give the left handed boys all the chance possible, and if they will attend to business, form habits of industry and virtue, they will come out far ahead of many others whose right elbows are too often on a level with their chins.

From W. F. A., *Toledo, Ohio.*—I have been somewhat amused at the letters from the boys in regard to left handed tinners, and I think "E. W." of Pulaski, whose letter appears in *The Metal Worker* of March 10, is right, and he comes close to my case. I have worked at the trade since 1856 and could and have used all of the tools that a right handed man did, but am now lacking a left handed monkey wrench.

Better Marked Stove Repairs.

From J. H. W., *Williamsport, Pa.*—The appeal of "J. F. T." in *The Metal Worker* of February 10 contains a good suggestion, that of the manufacturers pasting a label on the stove repairs with the name and number of the stove for which it is made, and I hope it will be followed, but I have grave doubts whether the manufacturers and jobbers will put themselves to the trouble. I do quite a stove repair business, and give my system of handling it. There are many other ways, such as having tags printed with the dealer's name and the names of the different parts of a stove, a vacant line for the customer's name, to be sent with the orders to the manufacturers that they may be fastened to the proper pieces. But all this costs money, and the dealers do not have time to do it. When a customer orders repairs for a stove or furnace from us we ascertain whether we have the repairs in stock, and if not we have a special blotter on which we put down the date, the customer's name and address and the several parts of repairs which he desires, and all the information in reference to the stove, with number, &c., that is necessary. Then we leave several lines of free space and make a memorandum, when the order is to be filled by freight or express, whether we are to deliver it and put it in place, and other remarks that are necessary. When we send the order to the jobber we add below each order the name of the customer, and request these repairs to be tied in separate bundles. When the repairs arrive with a small tag fastened on each package with the customer's name, we take our repair book and check off the goods received. We can tell at once by the small tags on the repairs for whom they were ordered and for what stove, and if the goods are not called for early, we can write the customer to drop in and get them; and if they are never called for, we write on the back of the tags the name and number of the stove to which they belong. We also keep a small ledger for stove repairs, from which we can tell at once what we have in stock. On the margin of the stove repair book we put down the name of the house to whom we have sent the order. I have found this a very convenient way of keeping track of repairs, but if any of the readers of *The Metal Worker* have a better way I should be pleased to learn of it.

Tin Cabinet for Coins.

From Fred M. Parks *Washington, Warren County, N. J.*—I am a reader of *The Metal Worker*, who tries to keep up in his business of an all 'round tinner. As a sort of relaxation I devote a little of my time to making a collection of coins, and will consider it a favor if some of your readers will suggest something in the way of a cabinet to keep them in. I want something that can be made of tin. I would also like to add if any brother tinner has an old or odd coin of any kind, I should like to hear from him and correspond with a view to purchasing it.

Furnace Gas Burner.

From I. W., *Philadelphia.*—Can *The Metal Worker* or any of its readers tell me where I can purchase a gas burner suitable to be used in a hot air furnace? The proposed change in the price of gas in our city has already made some inquiry for apparatus to use gas instead of coal for heating and by this means get rid of the labor and dirt attending the use of coal and disposition of the ashes made. Some of the readers of *The Metal Worker* in the natural gas district no doubt are using such a burner, either in hot air furnaces or steam and hot water heating apparatus, and I shall be glad to have them let me know what they use and some idea of the trouble experienced in their use and what is necessary to secure successful operation. I know that the pressure in our city mains will be nothing like as great as the pressure secured from natural gas mains, but think I can overcome this trouble by an adjustment of the burner.

Retinning Rusty Tinware.

From A. M. C., *Brooklyn, N. Y.*—Will some of the readers of *The Metal Worker* please give me a recipe for the acids used in retinning rusty tinware, and a description of the operation it should be put through?

Note.—We should be pleased to have the readers of *The Metal Worker* give our correspondent such information on the subject as they may possess. It is a question if tinware that has once become rusty can be retinned so as to produce satisfactory results. This would especially be the case with articles that were joined by soldering. We are informed that the rust can be removed from the tinware by placing the articles in a bath of dilute nitro-muriatic acid, the strength of which and the length of time the articles were to remain in the bath depending upon the depth of the rust. After being cleaned, the articles are to be dipped in clear water, when they are ready for retinning. A description of the process of retinning was published in *The Metal Worker*, August 22, 1891, page 42.

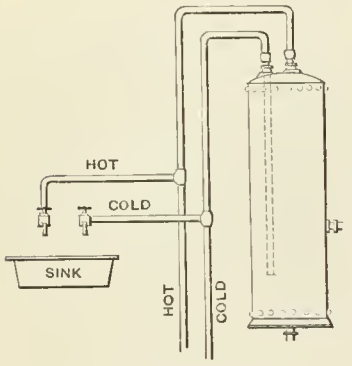
Finishing Lead Castings.

From H. L. C., *Chicago, Ill.*—Will you inform me through the columns of *The Metal Worker* how to coat hard lead castings in large quantities, so that they will have the appearance of tin or an alloy of tin and copper? I want to improve the appearance of the castings.

Answer.—We know of no better plan than to immerse them in melted tin and give a tin coating. This can be easily done by first dipping the hot castings in melted tallow and then passing them through a bath of tin. If our correspondent wants some simpler and more inexpensive method perhaps some of our readers may suggest a plan.

Hot Water From Cold Faucet.

From L. J. P., *Peru, Ind.*—Will some one inform me through *The Metal Worker* what causes hot water to come from the cold water faucet over the



Hot Water from Cold Faucet.

sink in the system of plumbing shown in the illustration and a remedy for it? The boiler is thoroughly clean, yet the flow was very weak until, by vigorous back pumping, it was increased.

School House Ventilation.

From H. SANDMEYER & Co., *Peoria, Ill.*—The importance of ventilation in our schoolrooms is at last beginning to attract the attention of thinking men all over the country. In the past month the National Association of School Superintendents held their annual convention in Richmond, Va. In discussing the proper systems of teaching they all agreed that the first requisite in a schoolroom is fresh air. They passed the following resolution:

Resolved, That each State should by law provide for the proper ventilation, lighting and heating of each school, and that there should be at least 1500 cubic feet per hour of fresh air provided for each pupil.

This is a step in the right direction. It is a crime against the coming generation to confine little children in air tight boxes, compelled to breathe impure air laden with the germs of disease, thus laying the foundation of pulmonary complaints in years to come. It has been demonstrated that fresh air can be provided in sufficient quantities to more than comply with this resolution without the aid of fans, gas or any machinery whatever.

The Greeley School of Peoria, Ill., is a 12 room building, constructed in such a way as to ventilate each room thoroughly. It is all done by means of flues, so arranged as to bring in this amount of fresh air and carry it out when vitiated. If one architect can do this every architect can. There should be a law in every State to make it obligatory upon school boards to see that this is done. They ought not to be content with any half measure, and certainly experience shows that it is no longer necessary to resort to guess work. It can be done with mathematical certainty.

The Metric System.

From A. O. S.—Please explain to me the system of weights and measures known as the metric system, to which I have recently seen reference made. What are the equivalents of the metric units in the common system?

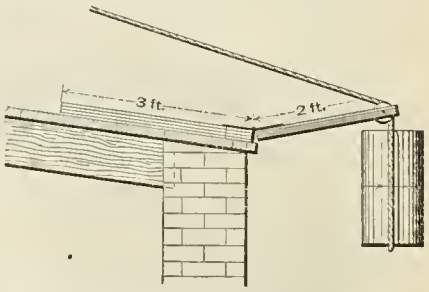
Answer. — Our correspondent has asked too comprehensive a question to be answered in full. We can, however, give him the principal units, so that he can understand the difference between the two systems. The base of the metric system is the meter, which is approximately 39 37 inches in length. The decimeter, centimeter and millimeter are $\frac{1}{10}$, $\frac{1}{100}$ and $\frac{1}{1000}$ of the meter in length. There are also other measures greater than the meter made by multiplying it by 10, 100 and 1000. The base of square measure is the square meter, equivalent to 1550.03 square inches. The square meter is also divided as well as multiplied by 10, 100, &c. The cube of these measures gives the cubic or solid measure. The common unit for liquids is the liter or cubic decimeter, which is equivalent to 1.056 quarts. The basis of the weight measurements is the weight of a cubic centimeter of distilled water, which is called a gram, equivalent to 15.432 grains. The measurement commonly used is the kilogram, equal to 2.2 pounds.

Fails to Bake on the Bottom

From J. F. L., *Baltimore, Md.*—If too much has not already been said in answer to "F. W.," Guelph, Ont., whose inquiry appeared in *The Metal Worker*, January 20, the following experience may be of interest to him. I take it that the vertical flue strip down the back of the stove or range, and also the horizontal one between the bottom oven plate and the bottom of the stove, are in relation to the stove or range as is a needle to the sewing machine, and all stoves or ranges to bake must have this plate. Now, assuming that the pipe is of the proper size, and the chimney has all the surplus openings closed and is one of fair draft, and the pipe is not pushed too far in the chimney or the neck of an elbow, then the stove should do good work. The coal being well ignited and the damper closed, if the coal is hard or too large, trouble will result surely, unless there is a very powerful draft, particularly if No. 2 Sunbury coal is used; for when the damper is closed the flame is dead a short distance from the fire box, and consequently there is but little heat to circulate around the oven and heat it. If coal of the same grade is used that is known as No. 3 Lykens Valley, the flame will extend more than half way across the top of the oven and throw a volume of heat under the oven, which can be further increased by the use of wood. This will further support my argument—which is, that a strong draft is required, and cooks often say that they get along much faster with pastry when wood is used. I have had many cases of stoves that failed to bake, and I conquered every one by providing a free draft.

Roofers' Elevator.

From L. M. W., *Delaware.*—Here is an illustration and description of a roofers' elevator that I have used with satisfaction in the absence of something better for hoisting rolls of tin to a roof



Roofers' Elevator.

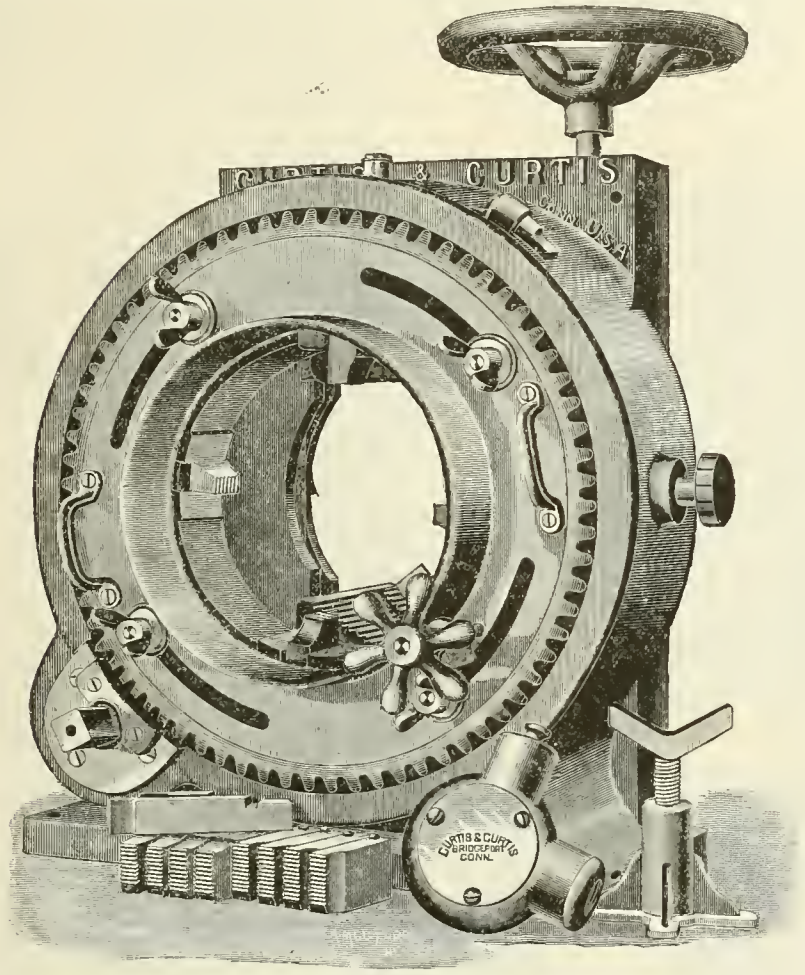
instead of carrying them up a ladder. It should be made of oak, 1½ inches thick and 6 inches wide, one part 3 feet long and the other part 2 feet long. Buy a 14 inch extra heavy strap hinge, a pulley wheel 4 inches in diameter with a ½-inch hole in it, and a ½ inch bolt, 6½ inches long. In the short piece of oak at one end saw a slot in the middle of the 6-inch side, 6 inches long and wide enough for the pulley wheel to turn easily. Bore a hole for the bolt to hold the pulley wheel and secure them in place. Fasten the two parts together with the strap hinge and it is ready for use. A strap made of band iron with holes in each end for screws or nails to hold it on the roof should also be provided when a considerable quantity of tin is to be raised. Standing on the long part will answer for raising a few rolls. In use, all of the short part hangs beyond the edge of the roof and a rope runs over the wheel to the ground, with a hook on the end for fastening to the roll of tin. By pulling on the rope on the roof it works easily over the pulley, raising the tin until the roll strikes the short part of the elevator, when an up pull will make the hinge double back and drop the tin on the roof.

Flat Seam Roofing Question.

From F. B K., *Delaware, Ohio.*—I notice in *The Metal Worker* of February 10 what "G. R. J." says about roofing. There is too much work done without knowing what it costs to do it, and a good many tinners reckon their cost by guess. A painter here tells the following story, which illustrates the way some tinners do their figuring. The painter figured on painting a house and filled a sheet of paper about 3 feet square with his calculations, and then, as there was no more room, said: "A cipher is a cipher, and 5 into twice you can't. Begob! I'll paint your roof for $50." If any of your readers have blanks for their men to fill out in getting at the cost of doing roofing I would like to hear from them; also examples of estimate blanks.

The Forbes Die Stock.

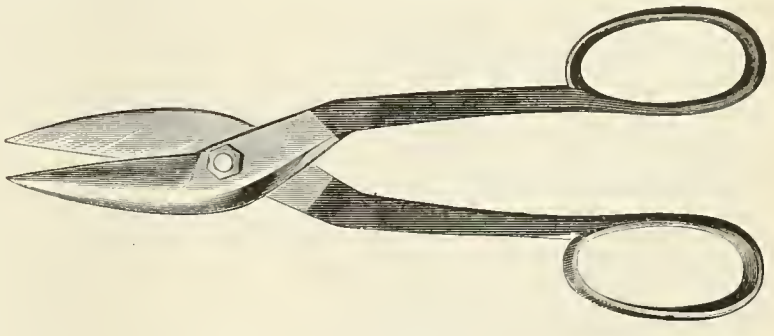
Curtis & Curtis of Bridgeport, Conn., have recently brought out a new development of the Forbes patent die stock. The cut shows a front view of a machine called, for purposes of identification, a No. 3 C hand machine, and it both cuts off and threads all sizes of wrought iron pipe from 2½ to 6 inches. As this machine weighs only 325 pounds it is easily portable from place to place and the work done on the spot, without the trouble and expense of carting the pipe to the shop and cutting it to measurement. In operating this machine the pipe to be cut is placed in the machine from the rear through the self centering vise, which clamps it and brings it central with the dies. The face plate is then turned to the proper graduation for the size of pipe to be cut, which sets the dies at standard size. Any variation of the fitting can here be allowed for, and the pipe cut either over or under standard size, if desired. The reversible ratchet wrench shown in the cut is then placed on the end of the pinion with a piece of pipe in it for a handle, and either by revolving it round like a crank or by ratcheting it like a pump handle the die carrying gear is caused to revolve. On the back of this gear is located a lead screw which causes the gear, as it revolves, to also recede into the shell and the dies are brought on to the pipe. When the thread is cut, instead of being obliged to revolve the gear back again to its original position, as was necessary with the old style of machines made by this firm, a turn of the knob, shown on the side of the machine, releases the lead screw, the dies are thrown back, the gear is pulled forward and all is ready for new work.



The Forbes Die Stock.

The Lyon Shear.

The accompanying cut represents a shear which Lyon, Conklin & Co. of Baltimore, Md., are putting on the market. The blades of the shear have outer faces of rounding shape, while the upper edges of the inner faces are also slightly rounded. The steel of the blades extends beyond the bolt, and the bolt thus passing through steel tends to prevent the loosening of the shear. The shear is described as being especially adapted to cornice and tin work, being so constructed as to allow of the cutting of scrolls, circles and other intricate work not within the scope of the ordinary shear. It is made for both right and left hand use.



The Lyon Shear.

A Mammoth Bottle.

Considerable attention was attracted March 9 by the exhibition of a mammoth bottle in front of the hardware, stove, plumbing and tinning establishment of M. Abbott's Sons at 137 Eighth avenue, New York. The bottle was made for the Emerson Drug Company, and is an exact *fac simile* of the bottle in which one of their specialties is sent out. It is to be used for advertising purposes here and finally sent to London for use there. The bottle is a piece of the handicraft of Patrick Keogh, the foreman of the sheet iron shop, and the raising work on the breast between the body and the neck of the bottle reflects credit to his skill. The bottle is made of No. 22 galvanized sheet iron and stands 9 feet high and is 3 feet 6 inches in diameter for a hight of 5 feet, when the breast gradually forms with a curve or swell into the neck, which is 2 feet 6 inches in diameter. The neck runs straight for 12 inches, when the mouth of the bottle flares to a diameter of 2 feet 4 inches and runs up 6 inches and is finished by a representation of a cork, which completes the hight. The bottle is so made that all the seams and joints are perfectly smooth on the outside, being soldered and then filed. On the inside a band covers all the seams and is thoroughly soaked with solder. A door is arranged near the bottom so that the bottle can be used for the storage of advertising matter and to enable a workman to get inside to straighten out any deformity that might be caused in transportation. The bottom of the bottle is made of 2-inch wooden plank to allow it to be bolted to a wagon for showing through the streets. The total weight of this pride of the sheet iron worker is 140 pounds, and he laments that it will cease to attract attention as a credit to his art when the painter transforms it into a giant representation of a bottle and label.

It is stated that the new shipbuilding programme of the British Government will consist of the construction of eight first class battle ships of the type of the "Majestic," at a total cost of $33,600,000.

Last week's real estate transactions in New York City materially exceeded in number and importance the dealings for the corresponding week of 1893, which was considered a very satisfactory one. Real estate men generally entertain hopeful views in regard to spring business. There is just now plenty of money seeking profitable investment, and there are indications that a considerable amount of it may flow in this channel.

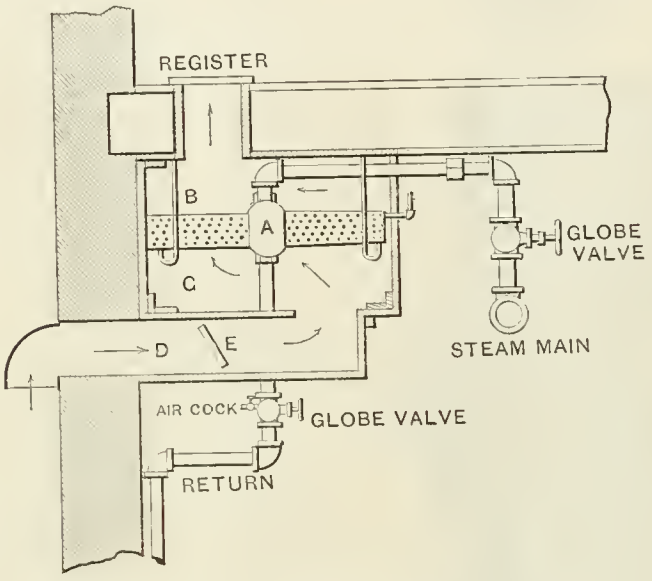
STEAM AND HOT WATER.

Indirect Radiation.

BY HELIOS.

In placing indirect radiation of any make a space of not less than 12 inches must be left above the radiators for a hot air chamber, and a space of 12 inches below the radiators for a cold air mixing chamber. If they are to be inclosed in wood or galvanized iron boxes, they will have to be supported with wrought iron hangers and supporting bars. If they are to be built in with brick work, the supporting bars can be built into the brick work. They must have a grade from the steam inlet section to the return outlet section, so that all condensation can drip out and leave no water in them to freeze, if the steam is down or the radiator is shut off. The steam supply must be taken in on top of the first section, and the return from the bottom of the last section. Globe valves must be placed in the steam and return pipes. Drill and tap a hole in the return valve back of the seat and put in a ⅛-inch air cock; this cock is to let out all water in the return pipe above the valve when the radiator is shut off. Place in the last section an automatic air valve.

The area of the cold air box should be not less than 1 square inch for each foot of heating surface in the radiation; the hot air pipe should have 1½ square inches area for first floor and 1 square inch area for second or third floors to 1 square foot of radiation. All registers must have openings full size of the hot air pipes. Always place the registers in the floor if possible, as the radiation will do very much more and better work than if they are placed in the side walls. If the registers are placed in the side walls it will take 20 per cent. more radiation to do the work than if they are placed in the floor. In placing the casing around the radiation great care must be taken to have the casing fit close to the radiation, so that no air can pass without going through the space between the radiation. Always connect the hot air pipe from the opposite end of the box from the cold air inlet.



Indirect Radiation.—Fig. 1.—Cross Section of Radiator, Casing and Pipe Connection.

The following illustrations will show the manner of connecting indirect radiation. All rooms that are warmed by indirect radiation must have ventilation of some kind to remove from the room as much air as is delivered into it. Without ventilation the indirect heating will be a failure. In placing all hot or cold air pipe, do not have any square turns; run the pipe as straight as possible; the cold air pipe can be taken from any cellar window and can be built of wood, tin or galvanized iron; galvanized iron is the best, as it can be made air tight and will take up less room than wood boxes.

Fig. 1 shows a cross section of indirect radiator casing and pipe connections. A is the indirect radiators. B, the hot air chamber. C, the cold air chamber. D, the cold air supply pipe. E, damper in cold air pipe to regulate the cold air supply to the radiators. Fig. 1 shows the register placed in the floor over the radiator. The cold air is taken through the side wall and connected to the casing of the radiation. Always place a damper in all cold air boxes, as shown at E. Fig. 1 shows the radiation inclosed in a wood stack box. The box is made of dry white pine beaded ceiling, not over 3 inches wide, for the sides and bottom; the top on the inside can be made of good quality matched flooring. The sides are secured to battens on the inside with screws and the sides and bottom are all put together with screws, so that the sides or bottom can be taken down at any time. The ceiling over the radiators and the sides down to the under side of the radiators must be covered with bright tin, put on smooth and secured to the wood work with tacks. The hot air pipe from B to register can be made of wood lined with tin or it can be a square tin pipe. Connect the steam and return pipes as shown in Fig. 1.

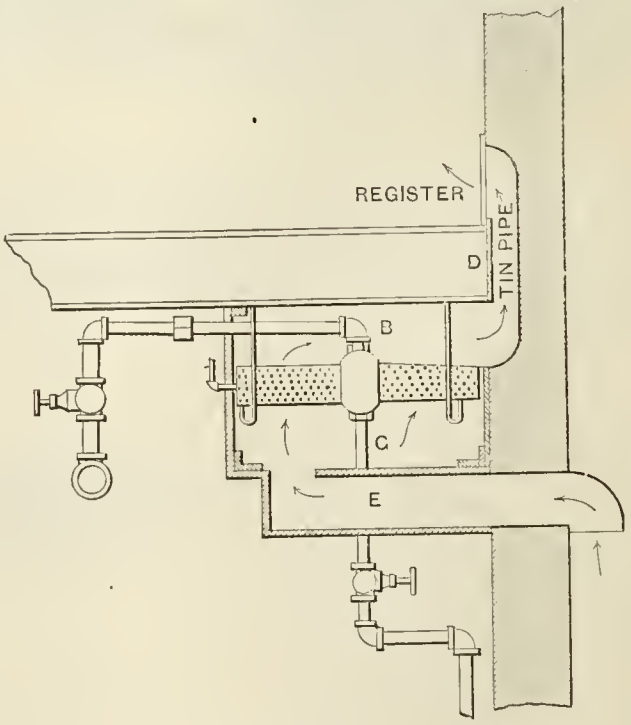


Fig. 2.—Indirect Radiator and Connections with Side Wall Register.

Fig. 2 shows a cross section of indirect radiation, same as illustrated in Fig. 1, with the hot air register in the side wall. The hot air pipe D, Fig. 2,

can be made of tin or galvanized iron. Always have a round top register box, and if the hot air pipe has to go in an outside wall cover it with two thicknesses of asbestos paper $\frac{1}{16}$ inch thick. Do not place hot air pipes in outside wall if it is possible to place them in the inside partition walls.

The Gurney Steam Boiler.

The Gurney Hot Water Heater Company, Boston, Mass., show commendable enterprise this season in putting on the market a steam boiler, views of which are presented in the accompanying illustrations. The company have been earnest advocates of water as a heating medium, and explain that they now come out with a full line of steam heating goods because their competitors who were formerly makers of hot water heaters alone, through consolidation of interests, forced them to meet concerns controlling both steam and water apparatus. In the accompanying illustrations Fig. 1 is a general view of the boiler and Fig. 2 shows it separate, revealing the internal construction and the distribution of the water surface. The boilers are direct surface burning, special claims being made for the arrangement of surface, which is staggered so that the heat of the gases is thoroughly extracted. Special mention is also made of the quickness of the boiler. Attention has been given to securing a steady water line, and the company claim that the means used are ample to secure this desirable result. Ample provisions have also been made for removing ashes from the ash pit and surfaces. A valuable feature to which particular attention is directed and in which the trade will be interested is that it is shipped in only three pieces. The body of the boiler is in two pieces and there are no water or steam joints requiring packing, the joints being in every instance screw joints, or iron to iron. The form of the waterways and distribution of surface is so clearly indicated in Fig. 2 that no further description is necessary. Special claims are made for the simplicity of the boiler, and the company say that in setting it up it is desirable to cover it with asbestos or mineral wool. The boiler, we understand, has been thoroughly tested, the company having employed an expert to determine its standing. They secured the services of W. J. Baldwin, M.E., of New York, who is well known to the trade and who furnishes the following report of his test: "The performance of the boiler during the trial was admirable, being steady and reliable, so that the steam did not vary ½ pound in pressure at the times of firing." Mr. Baldwin further states: "I never tested a boiler that gave as high an efficiency of evaporation per square foot of boiler surface."

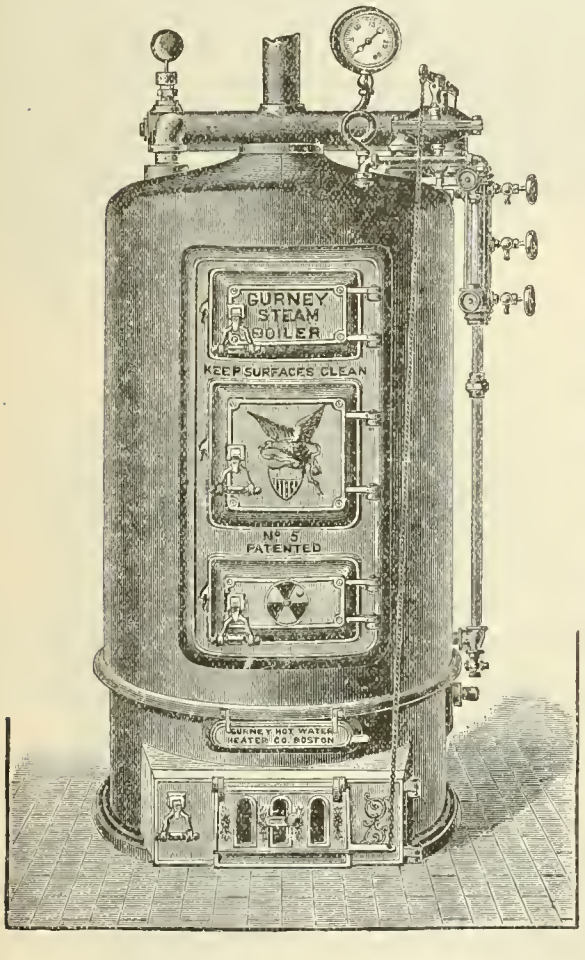

Fig. 1.—General View of Boiler.

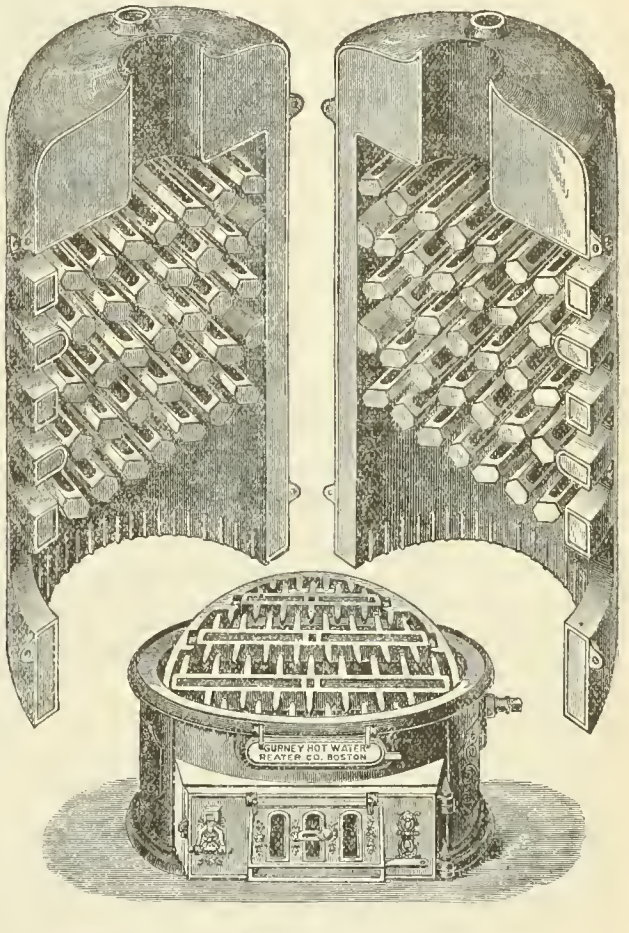

Fig. 2.—Boiler Separated Into Three Sections.

THE GURNEY STEAM BOILER.

HEATING NOTES.

The Greensburg and McKeesport business of the Pittsburgh Heating Supply Company has been purchased by H. Clymer Painter and S. J. Sloan. The new firm will be known as Painter & Sloan in Greensburg, Pa., and Sloan & Painter at McKeesport, Pa. They will do any kind of painting and tinning work during the coming year.

The calendar for the month of March sent out by M. Mahony, Troy, N. Y., is a very pretty reminder of the Mahony boilers. The calendar is a single card, with the days of the month in a panel at the bottom, while the chief feature of the decoration is the effect of the March wind on a young lady and her umbrella.

The latest postal traveler of the United States Heater Company, Detroit, Mich., calls the attention of the trade to the Mascot hot water heater, which is a small apparatus that has been put on the market by the United States Heater Company. It is intended for warming small residences, flats, conservatories, greenhouses, &c.; also for heating water for barber shops, baths, laundries, baptisteries, hotels, &c. The firm will soon have a steam heater out of the same general pattern.

The All Right and Volunteer boilers are the subject of a scarlet pamphlet issued by the manufacturers, the William H. Page Boiler Company, Norwich, Conn. These boilers are so well known that there is no need here of referring to their particular features. The All Right is a brick set boiler made in four sizes and the Volunteer a portable boiler made in seven sizes. In addition to the full description and illustrations of the boilers, themselves, other pictures are given

of some of the work done by the William H. Page Boiler Company. Two illustrations show the exterior appearance and interior of All Saints' Episcopal Church in Brooklyn, together with a diagram of the arrangement of surface. At the close are other cuts of residences, with a number of testimonial letters.

A HANDSOME red bound catalogue and price-list of Richmond heaters for steam and hot water is distributed by Albert A. Cryer & Co., 85 Center street, New York. The circular also calls attention to the Rex hot water heaters and hot water laundry stoves. The pamphlet of 23 pages contains numerous illustrations, full descriptions, tables of prices and sizes and some account of radiators.

THE SHERWOOD MFG. COMPANY, Buffalo, N. Y., issue a card directing attention to the Sherwood Injector, and also giving a list of a number of steam specialties that they manufacture.

THE MASON REGULATOR COMPANY, 10 Central street, Boston, Mass., are distributing an advertising novelty in the shape of a box of dominoes, with which the members of the trade can amuse themselves during leisure hours. The dominoes are made of hard wood, varnished on the side bearing the sunken spots, which, with the border and division mark, are in red. As the dominoes are issued primarily for advertising purposes, it is natural to find in connection with them some reference to the company and their specialties. Upon examining each domino there is found on its back a few lines indicating that the Mason regulators are adapted for steam, water and air, and also that the company make the Mason boiler feed pump. We understand that a set of these dominoes will be sent to any address on receipt of 12 cents to pay the cost of postage and packing.

RUBEL & Co., manufacturers of the Lily line of ranges, furnaces, steam and hot water heaters, 114-116 Lake street, Chicago, will move, May 1, to 75 77 Lake street.

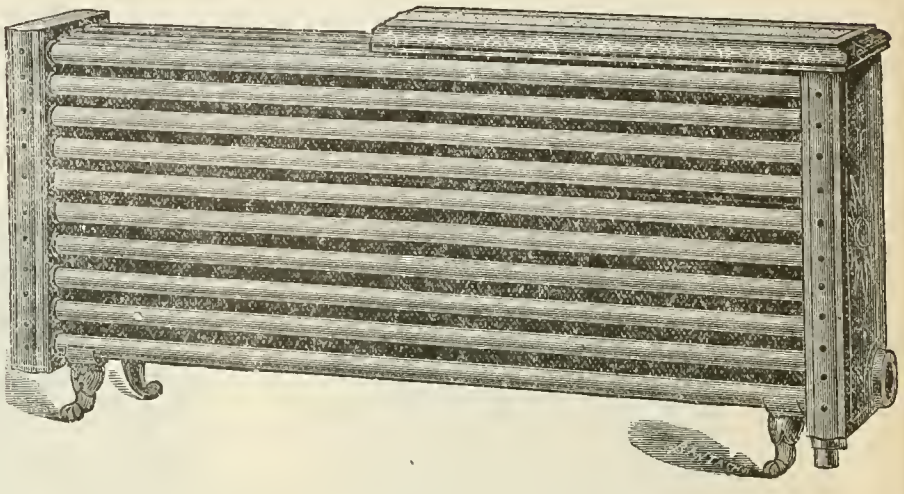
THE FULLER & WARREN COMPANY, Troy, N. Y., have closed a contract with F. O. Singer & Co., Baltimore, Md., for the exclusive agency of F. & W. Co.'s boilers, combination heaters, &c. F. O. Singer & Co. make a specialty of fine plumbing and hot water heating. They have been making some extensive improvements in their warerooms, having just fitted up two handsome offices in quartered oak and cut glass and repainted the interior to harmonize with the oak finish. The warerooms and offices will be heated with hot water from a F. & W. Co.'s boiler.

THE BABCOCK & WILCOX COMPANY are sending out a circular from their new office at 29 Cortlandt street, New York, directly opposite their old office, announcing their removal. It is a four-page sheet, containing half-tone engravings of their various offices in the different cities of the United States and at Havana, Cuba. It also has an engraving of a Babcock & Wilcox boiler with the statement that there are 1,500,000 in use and that they are manufactured in the United States, Scotland, Germany, Austria and France.

The lumber firms of Minneapolis have decided to consolidate, and, it is stated, have consummated a large deal of pine timber on the Upper Mississippi, comprising some 1,500,000,000 feet of timber.

The Windsor Hot Water Radiator.

We show in the accompanying illustrations elevation and sectional plan views of the Windsor hot water radiator made by the Windsor Heator Company, Galena, Ill. These radiators are made of ½-inch pipe, which subdivision of water, it is claimed, gives great efficiency to the radiator. They are also very light, and take up little space. Their appearance is described as ornate, and they are made in a variety of shapes to fit them for all uses. The radiators are made with pressed steel top, which is light and rigid; also ornamental wooden or marble tops can be furnished if desired. In Fig. 1 a general view of the radiator is presented with the top broken away showing the coils. The circulation in the radiator is indicated in the cuts Figs. 2 and 3.



The Windsor Hot Water Radiator.—Fig. 1.—General View of Radiator.

Fig. 2.—Section Showing Circulation of Water.

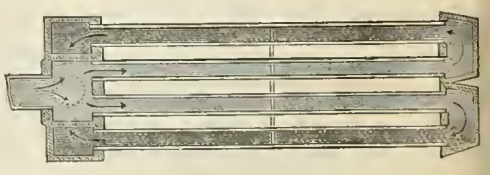


Fig. 3.—Section Showing Circulation of Water.

SCRAP.

N. & G. TAYLOR COMPANY, Philadelphia, send out a circular printed in red and black, showing in a negative way the advantages of the genuine Taylor Old Style Plate. The feature of the circular is a photographic reproduction of a piece of tin plate which they say was made by the same process as the imitations of the Genuine Taylor Old Style. The engraving, which is a half tone, has the appearance of an unsymmetrical sieve, due to the corrosion of the plate.

EXPORTS of tin plates from Great Britain to the United States during the month of February were 13,000 tons, as compared with 20,000 tons in the corresponding month of last year. The total exports to all countries for the month were 23,000 tons against 29,000 tons in February, 1893.

THE WORKS of the American Tin Plate Machine & Mfg. Company, at Linfield, Pa., are in full operation, making about 10 tons a day of finished plates. The specialty of the company is the production of continuous roofing plate, made by the Buckman process. The improved automatic continuous machinery at present in use is being duplicated, and the output will shortly be doubled. The company are said to have closed a contract for the entire output of the works for one year from February 1, 1894. The officers of the company are: P. B. Calvert, president; S. Y. Buckman, vice-president and general manager; and E. B. Smith, secretary and treasurer.

THE LEECHBURG FOUNDRY & MACHINE COMPANY of Pittsburgh, Pa., have secured an order from the Aetna-Standard Iron & Steel Company, Bridgeport, Ohio, for the changing of two of the steel mills of the latter concern into tin mills. This includes a new outfit of rolls, and also two 36-inch doubling shears with engine, two new cold rolling mills and one Mesta patent pickling machine, with vats, crates and everything complete. It is expected to have this work completed about May 1 next, at which time the Aetna-Standard Iron & Steel Company will be in position to furnish black sheets for tinning purposes. It is probable that within a short time after the above date the Aetna-Standard Iron & Steel Company will put in the necessary tinning machinery and will engage in the manufacture of tin and terne plate.

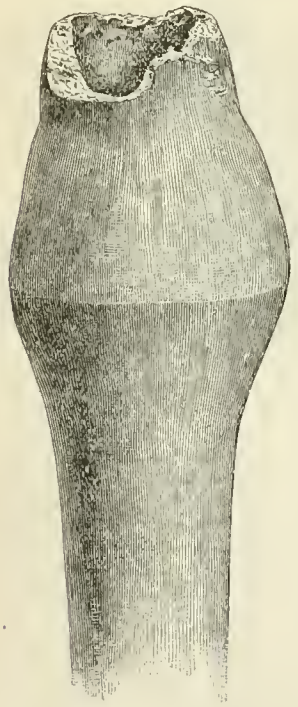
IT IS ANNOUNCED that a tin plate manufacturing firm in South Wales have recently secured several large orders from Russia for tin plates, to be used in canning beef. This is said to be an entirely new trade, and most acceptable to the Welsh makers, who are eagerly looking round for new markets for their product, to take the place of the waning American trade.

The Indian Government proposes to meet its revenue deficit by a general 5 per cent. duty on imports, including silver, and by doubling the present duty on petroleum.

PLUMBING and GAS FITTING.

Water Hammer in Boiler Connections.

The subject of the illustration was furnished by John Gormly, 1433 Columbia avenue, Philadelphia, and represents a piece of pipe which was taken from a job where he was called to make some repairs. The broken end shows the solder in a joint that was wiped on the side connection to a kitchen boiler, and which was swelled and broken, Mr. Gormly states, by water hammer. The enlargement is very uniform, there being no special swelling in one side as is usually the case, and it will be noticed that the solder has stretched quite as much as the pipe. The pipe is very heavy, ¾-inch pipe, which shows the power of the concussions which finally broke the joint, after a leak which occurred in the swelled part had been stopped by hammering metal into the



Water Hammer in Boiler Connection.

opening. To those who are not acquainted with water hammer it is explained as being due to steam that has formed in the water back passing to a point where it condenses, creating a vacuum which is filled by an inrush of water that strikes with a much greater force than is generally appreciated. When a water back is large and steam is generated freely this striking is frequent and the result is as shown. A larger opening or a water way of the full size of the pipe through the side connection would carry the steam into the boiler before it condensed.

THE PLUMBING FIRM of Blake & Burke, Rock Island, Ill., composed of J. D. Blake and T. F. Burke, was dissolved on March 5, Mr. Burke retiring from the firm. Mr. Blake will associate himself with D. T. Murphy to carry on the business under the firm name of Blake & Murphy. Mr. Burke, the retiring member of the old firm, will embark in the plumbing business on his own account.

TRAPS AND VENTS.

WM. BLAKE has opened a plumbing shop at Benwood, Ohio, a suburb of Wheeling, W. Va.

MANCHESTER, N. H., has passed a plumbing ordinance, to go into effect May 1.

J. WILLIAMS, Peru, Ill., is about to move his plumbing shop to the store next to Lang's jewelry store.

CHARLES DEDICKE, who has been employed in the factories of Alfred Dolge, at Dolgeville, N. Y., for something over 12 years as a plumber and steam fitter, has resigned his position and gone into business for himself. He has opened a store and workshop in the Spofford Block, under the Odd Fellows' Hall.

HENRY W. WERST, president of the Werst Plumbing Company, Louisville, Ky., died last week after a brief illness.

FAIR HAVEN MARBLE & MARBLEIZED SLATE COMPANY, Fair Haven, Vt., who make a specialty of reproductions of fine interior marbles, are wainscoting the church of St. Paul the Apostle, New York, using Lisbon, Alps, Green and Mexican Onyx, and are building a white marble altar for St. Patrick's Church, Pottsville, Pa. This concern also make a large line of plumbers' and builders' slate work.

P. FLEMING, Brattleboro, Vt., will add to his plumbing business a complete line of stoves and tinware.

THE DETROIT SANITARY SUPPLY COMPANY, Detroit, Mich., recently filed articles of incorporation. Capital stock, authorized, $100,000.

T. F. BURKE, Ernest Wagner and John Joers, Rock Island, Ill., have filed an application with the Secretary of State for permission to organize a company to do a general plumbing business. They have rented the two store rooms in the Buford Block, on East Seventeenth street, in the rear of Jonas Bear & Co.'s store. The company will carry a full line of heating and plumbing goods.

GEO. GOODSELL, the plumber who has been working for Williams Bros. for the past two years, has resigned his position. Mr. Goodsell and Dan Pickett will open a shop in Music Hall Block, at Crawfordaville, Ind.

THE NEWTONVILLE HEATING & PLUMBING COMPANY opened their place of business in Tremont Block, at Newtonville, Mass., last Monday.

C. A. HASTINGS will engage in the plumbing business as a member of the firm of Crosbere & Hastings, Claremont, Mass.

THE PHILADELPHIA BOARD OF CITY TRUSTS contemplates the establishment of a plumbing class at Girard College, in that city. One of the members of the board recently inspected the Master Builders' Mechanical Trade Schools at the Builders' Exchange, Philadelphia, to gather information in regard to the successful plumbing class which has been in operation there for some years.

NAPOLEON MYETTE AND ZENON ST. AUBIN, plumbers, of Montreal, Canada, have dissolved partnership.

THOMAS ASHE has sold out his plumbing business at Knoxville, Tenn.

THERE was recently incorporated at Indianapolis, Ind., the Aluminum Bath & Mfg. Company, to manufacture and deal in aluminum bathtubs and specialties. Capital stock, $9000. Directors, B. F. McFarland, A. C. Jenks and L. W. Forbes.

HARWOOD & GILDER, plumbers, will move into the Market street store room, Warren, Ohio, now occupied by Mikesell & Shaffer, April 1.

THE MAYOR OF BUFFALO, in addressing the master plumbers' convention, spoke of 150 miles of well cleaned asphalt streets, a fine system of sewers, and attributed the fine sanitary condition of the city to the aggressively progressive plumber.

SECRETARY CHAS. SCHLOESSER of the Master Plumbers' Association of New York City was elected secretary of the State association at the convention at Buffalo.

COULMAN & WESCOTT, Fair Haven, Vt., are furnishing the slate work for lavatories and closets for two new public schools at Holyoke, Mass.

PRESIDENT DANIEL G. FINNERTY of the National Association of Master Plumbers has forwarded to the relations of James G. Weldon, at Pittsburgh, who died a short time ago, a letter of condolence, expressing the great loss sustained by the National Association in Mr. Weldon's death.

THE BUSINESS formerly conducted by Worden & Brady, Bayonne, N. J., which was dissolved on January 1, is being conducted at the old stand, 667 Avenue D, by Walter Worden, who conducts a first-class plumbing business, besides keeping on hand a general line of hardware, house furnishing goods, stoves, ranges and heaters.

THE PHILADELPHIA COUNCILS HIGHWAY COMMITTEE on the 12th inst. met to consider the ordinance to regulate the issue of permits for opening streets and roads and the charges to be made therefor. A number of plumbers were present. The ordinance requires that each permit for an excavation in a public highway shall be taken out before the work is commenced; that it be kept at the place of excavation while the work is being done, and be exhibited whenever called for by the police or other persons having authority to examine the same. The ordinance also provides that a contractor taking out a permit shall make a deposit of $50 to cover any expense which the city would be put to in repaving the street.

The plumbers strongly opposed the ordinance as framed, claiming that considerable difficulty would arise in the way of making an estimate as to the cost, different prices for different paving being provided for in the ordinance. The bill was finally deferred until Monday next, when final action will be taken.

GEORGE W. LARSEN, formerly connected for many years with George C. Blessing & Co., has begun business for himself at 56 Beekman street, New York City, as manufacturers' agent for the sale of plumbing materials. He also makes a specialty of slab and marble work.

R. A. DODSON, late with C. L. Keck's plumbing department, has opened a store in the Myers Building, on Berwick street, Whitehaven, Pa.

THE WILKESBARRE, PA., firm of Stevens & McGrath, heating and ventilating engineers, sanitary plumbers and sheet metal workers, have been succeeded by Stevens, McGrath & Gilchrist. The new partner is Wm. B. Gilchrist. They will shortly remove from Lincoln street to 180 East Market, where they will have increased facilities.

SCOTT & AHEARN have broken ground for their new plumbing establishment, corner of South Washington avenue and Atwater street, Saginaw, Mich.

THE FIRMS of James H. Spence & Co. and E. T. Doyn have been consolidated under the firm name of Doyn & Spence. The new firm will continue business at the old stand of J. H. Spence & Co., 122 Grand avenue, Milwaukee, Wis.

THE FIRM of Sullivan & Macbeth, Mankato, Minn., dissolved partnership, and Mr. Macbeth will carry on the plumbing business at the old stand.

THE BRANDT SUBMERGED WATER HEATING COMPANY, 22 Drummond Block, Toledo, Ohio, are issuing circulars of their heater, which is adapted for bathtubs, baptistries, &c. The apparatus is weighted to set down in the water and uses either gas or gasoline to heat the water. It is stated that the water in a bathtub can be raised from 50° to 115° in temperature in from 15 to 25 minutes.

THROUGH the kindness of City Inspector of Plumbing Samuel A. Robinson, Washington, D. C., we receive a copy of the amendments to the plumbing regulations of the District of Columbia.

AN ODE to the sixth annual convention of master plumbers of the State of New York, composed by a plumbing bard, was set to the tune of "Auld Lang Syne" and sung by over 200 voices at the close of the convention.

THE L. WOLFF MFG. COMPANY, Chicago, are to establish a branch store for the sale of their plumbing goods at Minneapolis, Minn., from where orders can be filled. The store and basement at 11 Washington avenue, North, has been leased and will be placed in charge of F. J. McArdle.

J. A. FAIRBANKS & Co. have opened a new stove and tinware store and plumbing establishment in the Burr Block, on Main street, Brewer, Maine.

MICHAEL J. DUNNE has been appointed by the Board of Health Plumbing Inspector for Kingston, N. Y., with a salary of $750.

The Chicago Master Plumbers.

The Chicago master plumbers held a meeting at their rooms, 197 Madison street, Monday evening, March 12. The meeting might have been likened to a theater where the manager was obliged to post a notice "Standing Room Only," so great was the attendance. It was cheering to the heart of President Paul Redieske on his return to take up the duties of his office, blessed with renewed health and vigor, to see the large number present to welcome him home.

Quite a discussion ensued regarding the best means to employ for protecting plumbers from loss from irresponsible parties. Instructions were given to the Arbitration Committee as to the articles of agreement to be entered into with the journeymen plumbers. Resolutions of condolence to the family of Jas. G. Weldon, Pittsburgh, deceased, member of the National Executive Committee, were adopted by a rising vote. The secretary was ordered to have the following engrossed and mailed to Mr. Weldon's family:

We have learned with the deepest regret of the death of our friend and associate Mr. Jas. G. Weldon of Pittsburgh In view of the exalted character of our departed brother, and of his many acts of kindness and generosity which make his memory dear, it becomes our manifold duty to offer words of sympathy and condolence to the members of his bereaved family, and also the members of the Master Plumbers' Association of the city of Pittsburgh, of which he was a most noble and worthy representative.

Be it therefore resolved, That through the death of Jas. G. Weldon we have lost a dear friend and brother, and that the National Association of Master Plumbers has been deprived of one of its most faithful and devoted officers and most loyal adherents.

Resolved, That we cherish the memory of the dear departed, and be ever faithful to those principles of right, justice and truth for which he was so eminently favored, and for which he so earnestly labored during his brilliant career.

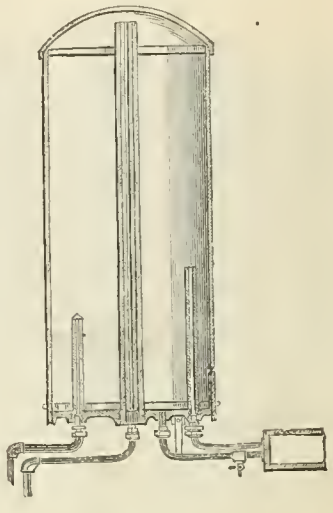
Resolved, That the Chicago Master Plumbers' Association in deepest sorrow extend its most sincere sympathy to the members of his afflicted family.

Resolved, That the Chicago Master Plumbers' Association prove that distance is no barrier to brotherhood, and that while their Pittsburgh associates are mourning for their honored member, we too would mingle our grief with theirs in bonds of unity and true fraternity.

Duncan's Patent Circulating Boiler.

The illustration herewith is of a circulating boiler placed on the market by W. E. Duncan of Forty-ninth street and Woodland avenue, Philadelphia. The cold water supply pipe enters the boiler through the bottom, and is carried upward 12 inches, making it non-siphonable; the top of the pipe has a deflector to throw the cold water to the bottom. The top circulating pipe is carried 18 inches up into the boiler and the bottom circulating pipe discharges direct from the bottom of the boiler into the water back. The hot water is taken from the top of the boiler by means of a tube within a tube, allowing of a circulation of air between them, with an opening at the bottom. This, it is claimed, enables the hot water to be discharged from the bottom of the boiler, without coming in contact with the cold water. The bottom shell of the boiler is made with three legs under it, to which connections are made, thus affording free access for a wrench.

The advantages claimed for the boiler are that outside piping is done away with; that there is a saving in the quantity of pipe necessary for connections, consequently a saving in the labor incident to making connections; it can be placed on any boiler stand, on brackets or on the floor; it may be placed on the floor of a bathroom, thus,



Duncan's Patent Circulating Boiler.

without loss of efficiency, answering the purpose of a hot water radiator and necessitating only an outlay sufficient for a few feet of circulating pipe, the supply and hot water pipes being connected at the bathtub.

The Fourth Annual Ball of the Cape Cod Commercial Travelers' Association was held at Odd Fellows' Hall, Boston, on Friday evening, March 9. Many well-known traveling men connected with the trades represented by *The Metal Worker* are members of this organization. Among those in attendance were: J. S. Crapon, with St. Louis Stamping Company, Boston, Mass.; Geo. E Hunt, with Henry N. Clark, Boston, Mass.; Andrew Hawes, with S. G. Davis & Co., Boston, Mass.; E. L. Richards, with Frye, Phipps & Co., Boston, Mass; J. F. Randall, with Baldwin, Robbins & Co., Boston, Mass.; F. E. Mayo, with Dame, Stoddard & Kendall, Boston, Mass.; W. B. Bangs, Provincetown, Mass.; E. F. Keeler, Hudson, Mass.; W. H French, West Newton, Mass. There was a concert from eight to nine followed by dancing until two. About 100 couples participated, and the entertainment was a complete success. J. S. Crapon and George E. Hunt, among others, were active as floor managers.

A widely circulated report that Philip D. Armour, the Chicago millionaire, had given $500,000 for the establishment of a trade school in San Francisco, is denied by Mr. Armour. He says he has no such intention.

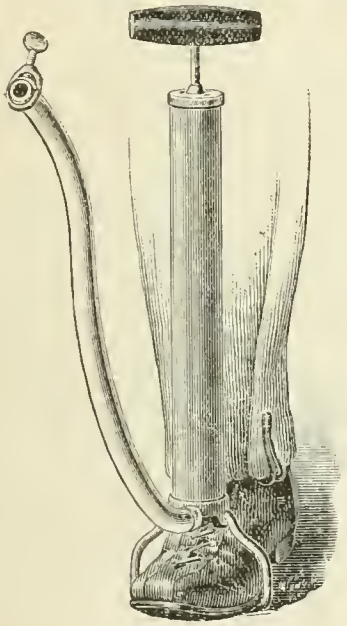
The authorities of Binghamton, N. Y., have declared the nickel in-the-slot machines to be gambling devices, as construed by the penal code.

Dr. Ernest Hart, of the *British Medical Journal*, expresses a belief that within the next 30 years cholera will become extinct before the march of sanitary science.

THE RETAIL STORE.

Heath's Ball Valve Pump.

The accompanying cut represents a bicycle pump, put on the market by S. F. Heath Cycle Company, Minneapolis, Minn. The barrel is 1¼ x 12 inches in size, and the pump is capable, it is stated, of raising a pressure of 100 pounds to the square inch. Attention is directed to the universal coupling on the end of the hose, by means of which, it is explained, connection can be easily and quickly made with any valve. The stirrup in which the foot is placed is



Heath's Ball Valve Pump.

hinged to allow the barrel to oscillate with the motion of the hand, and may be folded back against the barrel when carrying the pump. It is stated that the pump weighs about 2 pounds, and that it may be carried on a wheel if desired. The pump is nickel plated and guaranteed by the manufacturers not to break.

Solid Steel Seamless Kettle.

The Cleveland Stamping & Tool Company, Cleveland, Ohio, are offering solid steel seamless kettles, as shown

Solid Steel Seamless Kettle.

herewith. The kettles are referred to as being made seamless from cold rolled wrought steel. A feature of the kettle is the handle for tipping, when emptying its contents. A full line of these goods are made of flat and round bottom deep kettles, maslin kettles and stew pots, which are furnished either polished inside, tinned or enameled.

The Sanitary Garbage Pail.

The cuts here shown represent the sanitary garbage pail, offered by Sanitary Garbage Pail Company, 87-89 Shelby street, Detroit, Mich. The pail is made of galvanized iron, and is usually attached to an alley fence, or where it is easily accessible to the garbage collector. It requires a space of 12 x 24 inches, is filled from inside the premises and emptied from without. The pail can be removed from the fence for emptying into the collector's wagon, the collector being supplied with a master key to unlock the pail, which secures the exclusive use of the pail to the owner. When the pail is replaced in the trunnions and pushed back into

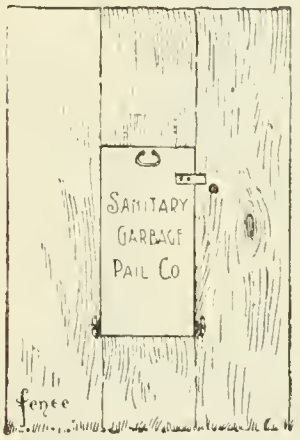


Fig. 1.—The Sanitary Garbage Pail.

position it is stated that it closes its cover and locks itself. It is remarked that it works perfectly in winter, it being 18 x 12 inches at the top with a 2-inch radius bottom, and when upturned the weight of the contents forces the matter to fall out. The point is made that this obviates the use and

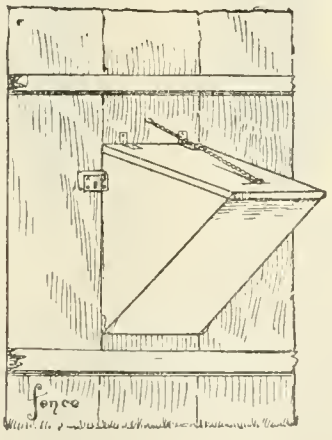

Fig. 2.—Pail Inside the Yard.

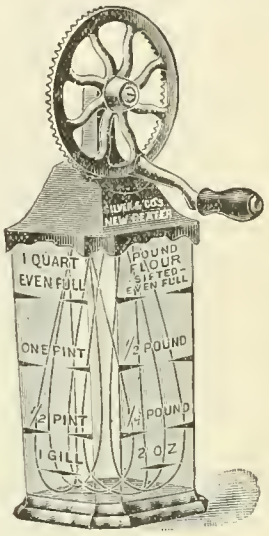
possible penetration of the receptacle by the insertion of a shovel or pick.

New Beater and Dessert Maker.

Silver & Co., 304-310 Hewes street, Brooklyn, and 20 Warren street, New York, are offering a beater and dessert



New Beater and Dessert Maker.

maker, as shown herewith. The receptacle is of glass graduated, and may be used separately for measuring and weighing liquids, sugar, flour, &c. The top is of tinned iron, with a wheel 4 inches in diameter. The wire beaters are rigid at the bottom, being bound together by wire. The device is a combination beater and measure for beating eggs, whipping cream and for making cakes, custards, &c.

Aluminum Products.

The Wohler Aluminum Company, 55 Jackson street, Chicago, issue a 28-page catalogue, giving full particulars of the great variety of aluminum manufactures now offered by the company, who are representatives of the Pittsburgh Reduction Company, Western agents and distributors for a great many producers of aluminum goods, and also manufacturers of the metal in some special lines. They offer Ingot Aluminum, Castings, Plates and Sheets; Seamless Tubing, Bars, Angles, Channels, Beams, Tees, Rods, Wire, Leaf, Foil and Bronze Powder. Tables of gauges, weights and dimensions are given whenever such particulars are desirable. A considerable part of the catalogue is devoted to aluminum cooking utensils, which resemble silver in appearance, are made of the solid metal, have no enamel, and are claimed to be practically indestructible. The line of these wares which are offered covers Saucepans, either bailed or handled, Fry Pans, Bake Pans, Wash Bowls, Dippers, Cups, Coffee Pots, Tea Pots, Hotel Stewpans, &c. The company are about to put on the market a full line of Spoons, which will closely resemble sterling silver, being composed of aluminum mixed with a sufficient quantity of silver and other high priced metals to make a combination of sufficient density or hardness to be suitable for table ware. The catalogue further contains a comprehensive list of novelties, fancy goods and specialties in aluminum, including jewelry

ROOFING AND CORNICE.

Fred F. Bischoff & Co.

One of the most complete factories in the country for the manufacture of ornamental sheet metal work has just been completed at Libertyville, Ill., by Fred F. Bischoff & Co. It comprises two buildings. The larger is 225 x 60 feet, one story high, and is divided into several compartments. In the center are the boiler and engine rooms. An engine of 100 horse-power, built by the Erie City Iron Works of Erie, Pa., furnishes the power. Adjoining the engine room is the stamping room, in which are ten presses, five of them being operated by power and the others by hand. The large presses are of the firm's own design. They are powerful presses, with very heavy bed plates and massive foundations. The largest of these has a bed 30 inches square, and is used for making imitation brick siding, rock faced siding, ceiling, Spanish tile, &c. It will turn out 6000 square feet a day, the sheets coming out perfectly straight, without a buckle. The other presses are used for making moldings, ornaments and special designs in pressed metal. The company manufacture all their own dies and make their own patterns in the pattern shop next to the stamping room. Here designers are constantly at work. Models are first made in clay, after which patterns are produced in plaster and subsequent copies are made in wax. Architects' sketches are thus worked out, often from mere suggestions. The patterns are then used for molding zinc dies in sand. Two pots melt the zinc for these castings. At the opposite end of the same building is the paint shop, in which 10,000 square feet of sheet metal can be painted in a day.

The other building is 180 x 60 feet, two stories high. The whole of the second story is thrown into one room, which is well lighted, has a high ceiling and forms an ideal workshop. It is used for making sheet metal bathtubs and for general tin work. The bathtubs are constructed of galvanized sheets, shaped on a very large brake built by Geo. C. Keene & Co. of Cincinnati. It is operated either by power or hand and will take an 8-foot sheet. The tubs are shaped like porcelain or cast iron tubs and are handsome in appearance, being enameled inside and outside, finished with a rim of polished hardwood and decorated with electroplated pressed zinc ornaments. They are very light, yet strong and durable, and in cost occupy a position intermediate between copper and cast iron tubs. When running full this department could turn out 50 tubs per day. This is the only establishment in the country making tubs of this character. The lower floor of the same building is used for offices, spinning and soldering and shipping. The spinning and soldering department is an important feature of the works. Here fine ornamental work is put together. A number of colossal sheet metal statues are now on the floor receiving their finishing touches. Two of these are statues of Justice, one represents Liberty and another Gambrinus. In this room is a large power punch press for heavy work. A novel departure in sheet metal work completed in this room is the manufacture of sheet steel dashboards for buggies. These are made of two pieces of sheet metal, which are separately pressed with stiffening ribs, then put together and lap seamed, after which they are japanned, and present an exact imitation of a leather dashboard. The shipping room is fitted with a large number of racks in which are stored pressed metal moldings, ornaments, &c., each rack being numbered to correspond with the numbers in the firm's catalogue, thus facilitating the work of the packers and shipping clerks. From this room a platform extends outside on a level with the floor of a freight car. A side track runs to the works from the Chicago, Milwaukee & St. Paul Railroad, giving the firm excellent receiving and shipping facilities.

The buildings are of frame but are very substantially built and are covered with the firm's steel rock faced siding, presenting an extremely pleasing appearance. The works are lit with gas manufactured on the premises. The firm's specialties are ornamental sheet steel ceiling, roofing and siding; steel, copper and tin Spanish roofing tile; sheet metal ornaments of every description; sheet metal bathtubs and statuary. Their main office and warerooms are 24 and 26 West Lake street, Chicago.

Conductor Reducers.

We show in the accompanying illustrations two forms of conductor reducers, manufactured by the Garry Iron & Steel Roofing Company, Cleveland, Ohio. Style A is shown in Fig. 1 and is made to take the pipe straight into the top, while style B, shown in Fig. 2, will take the pipe in at an angle, saving the use of elbows, before the pipes enter the reducer. The manufacturers, however, recommend the style A, as the water enters straight with the reducer and will flow through better.

Fig. 1.—Style A.

Fig. 2.—Style B.

Conductor Reducers.

FLASHINGS.

THE F. J LEWIS ROOFING & MFG. COMPANY, Omaha, Neb., are erecting on their grounds, at Eleventh and Nicholas streets, buildings for the manufacture of roofing paper, building paper, prepared paper, and for the distillation of cold tar pitch.

"THE LIFE OF AN IRON ROOF, or How Long will it Last," is the title of an instructive little book upon a most interesting subject which is distributed by the Cincinnati Corrugating Company of Piqua, Ohio.

THE WORKMEN of T. B. Dewees & Co., Phœnixville, Pa., are engaged in tinning and spouting a large building at the Bean sand crusher, at Valley Forge.

A NOVEL CIRCULAR is issued by Gara, McGinley & Co., 13 South Seventeenth street, Philadelphia, Pa. It is a reproduction of a series of advertisements that are now running in the Philadelphia street cars. They are cleverly worded and all of them are attractive. An example of these advertisements is: "Say a little but say it strong. We do one thing well. We mend roofs. Everywhere is convenient to us—telephone—street cars—walking. Roofers in tin, copper, slate and tile. Gara, McGinley & Co., 13 South Seventeenth street."

THE CONTRACT for the copper cornice work, slate and composition roofing, skylights, &c., for the City Hall, Milwaukee, Wis., has been taken by C. W. Rickert, 194 Clark street, Chicago.

THE COLUMBIA CORRUGATING MFG. COMPANY, Niles, Ohio, manufacturers of all kinds of iron and steel roofing, have a factory at Niles measuring 60 x 200 feet, and one at Chicago 100 x 100 feet in size. The firm expect to add other items to their present line of work as fast as they can be reached. Their present equipment consists of machinery for the manufacture of roofing, corrugating iron, galvanized sheets, metal lathing, &c. This concern will at once apply for a charter of incorporation.

THE WHEELING CORRUGATING COMPANY, Wheeling, W. Va., have recently added to their equipment machinery for the manufacture of galvanized steel and tin eaves trough, conductor pipes, hangers, &c. This machinery has been put in operation and is working very satisfactorily. This firm are now in position to fill all orders for this material promptly, and expect to become one of the largest producers of it. They have recently gotten out some new ceiling designs which are shown in their new catalogue. A branch office has recently been opened at 472 Laflin street, Chicago, at which location a stock of everything made by the concern is carried for the convenience of trade tributary to Chicago.

H. FITZBERGER & SONS of 213 Park avenue, Baltimore, Md., have recently completed a large contract for copper work on the Ohel Sholom Temple, a new Jewish synagogue in Baltimore. The work consists of a dome lantern 15 feet high and 8 feet diameter, with a

large circular Fitzberger patent skylight at the base, a dome base about 20 feet high, with star windows and mosaic ornamentation, and all the cornice work in the building.

An important deal in slate is reported from Bangor, Maine, as having just been consummated. The Monson Slate Company of that city have purchased the entire Merrill slate quarry property in Brownville at a cost of about $300,000, thus consolidating the most important quarries in Maine. It is thought that this action will result in better prices for all slate products and promote business in that district.

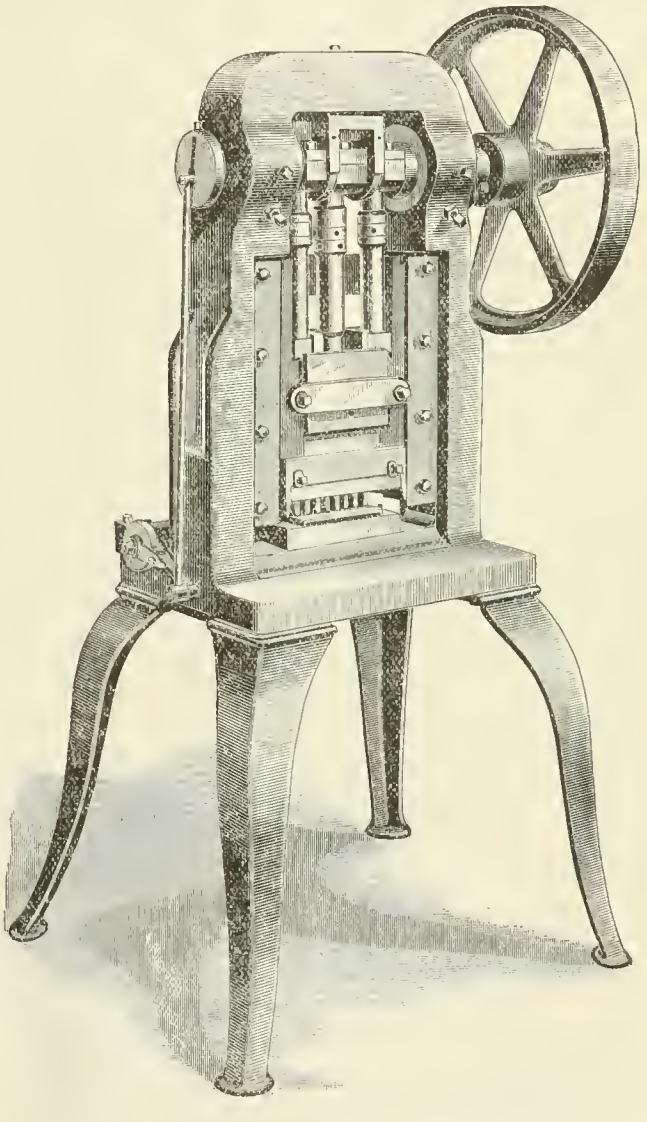
The catalogue lately issued by the Wheeling Corrugating Company of Wheeling, W. Va., is a handsome example of trade publication and is worthy of the fine work done by this concern. It is of pamphlet style, contains 30 pages and measures 12 x 9 inches. The binding is in brown cardboard, with a stamped design on the front cover printed in silver. The publication is devoted to continuous ceiling designs made by the Wheeling Corrugating Company, who also manufacture patent steel ceilings, roofings, corrugated iron, eaves trough and conductor. The text of the catalogue directs attention to the advantages of continuous steel ceiling, which does not limit user to a few fixed sizes of paneled plates. The remainder of the text is briefly descriptive of the ceilings and also includes directions for applying them, one of the illustrations being a sectional view through a ceiling and cornice, illustrating the application of the sheet metal. The chief feature of the book is the half-tone engravings of the designs themselves. A large variety of different designs are illustrated and it is needless to say that many of them are exceedingly attractive and all of them are reproduced with great beauty and accuracy in the photo-engraved illustrations. The engravings show designs, small sections and full ceilings, likewise interior views of apartments finished with these goods. At the end of the book, illustrations of embossed and corrugated sheets are given.

The Porter Iron Roofing & Corrugating Company, 101 and 103 West Front street, Cincinnati, Ohio, desire to deny most emphatically the report that they intend to remove their works from Cincinnati. This report found its way into our columns in the issue for the 3d inst., and was apparently based on good authority. The company, however, state that the report is absolutely false with regard to them. They have been established in Cincinnati for upward of 20 years and now claim to be the oldest established iron roofing concern in the United States. They have done business so successfully and satisfactorily at the old stand that they have no intention of abandoning it. The foundation for the report is the fact that one who was formerly connected with the company proposes to engage in business for himself in Indiana.

A striking illustration of the depreciation that has taken place in the value of industrial securities during the past year is reported from Lowell, Mass. A calculation of the present selling value of the stocks of the leading manufacturing companies in that city shows that they have lost in the aggregate fully $3,000,000, as compared with a year ago.

Double Action Gang Power Press.

This press has a roll feed attachment, which is stated by the makers—the Cross & Speirs Machine Company of Waterbury, Conn.—to be accurate in its movements. The shaft is of steel, with copper and tin boxes. The gate or slide is unusually long and is provided with large bearing surfaces; it runs in copper and tin ways, which may be set close without heating, thereby preventing the tools from shearing. The machine will cut and draw from 4 to 20 shells at every action of the slide, and it may be run at 230 revolutions per minute. Two sizes of this press are built, one weighing 1400 pounds and the other 2000 pounds.



DOUBLE ACTION GANG POWER PRESS.

The announcement of a new course in practical chemistry at the Brooklyn Polytechnic Institute is exciting much interest. The course includes thorough instruction in experimental chemistry and the various branches of chemical analysis, pure and applied chemistry, and other branches necessary to the analytical and technical chemist. Special attention is to be paid to instruction and laboratory work in organic chemistry, and also to the study and testing of technical products, wastes, processes, &c. The new laboratories are commodious and are provided with the apparatus and chemicals required in analytical, experimental and research work. The course will include physics, modern languages and drafting. The study of chemistry begins in the freshman year, and in each successive year will occupy more of the student's time. Facilities are also to be given for post-graduate work in both pure and applied chemistry and in chemical engineering. The new chemical course will be under the direction of Peter T. Austen, late professor of chemisty in the New Jersey State Scientific School and Rutgers College. He will be assisted by William M. Grosvenor, Gillett Wynkoop, H. M. Baker, Jr., and others.

So many fishing vessels have been lost this winter that the Gloucester, Mass., builders are crowded with orders for new craft. Their yards will be kept very busy for several months.

A plan has been submitted by the engineers of the Brooklyn elevated railroads for a superstructure to be built over the existing railroad on the Brooklyn Bridge, in order to allow the elevated trains to run directly into New York. Mr. Roebling, who was one of the builders of the bridge, declares emphatically, however, that the added structure would impair its safety and has reported unfavorably on the scheme to the bridge trustees.

Press Working of Sheet Metals.—III.

BY OBERLIN SMITH

Dies.

Having in the previous chapters attempted to define, briefly describe and to some extent classify presses of various kinds, it will now be well to define the tools complementary thereto which are known as dies, and at any rate in a practical if not in a strictly scientific manner. Such dies, as far as sheet metal work is concerned, may be defined in general as a pair of special tools so related to one another that when properly guided and approached toward each other, with sufficient pressure, they will produce a definite, uniform and permanent change upon each one of certain similar pieces of proper material placed between them.

Classification by Functions.

Like presses, they are somewhat difficult to classify, but not to so great a degree. In this treatise I will classify according to their functional character only, and will not attempt to do so by the material they are made of, by the kind of press they are fitted to, by their method of construction, or any other of a dozen systems that might be contrived. In each class, as, for instance, cutting dies, there will be necessarily a number of varieties, based somewhat upon the material to be worked and the condition in which it is to be put. No attempt will be made at a disquisition upon the art of die making, as this might well occupy a complete volume in itself. The chief purpose of these chapters is to describe the operations practiced by the sheet metal worker, as

he views them from his standpoint, or, rather, as he should view them. In carrying out this idea it has been necessary to refer to the different forms of presses without going into the details of their mechanical design. Dies will be herein treated the same way, only such details of their construction being given as are necessary to illustrate their action, both in theory and practice. In describing each general class some advice may be given as to certain good points in these tools which should be looked after by their users, but the methods of manufacturing them and their exact design, as far as concerns the best modes of putting together, &c., will be left to the unknown makers thereof.

While speaking of dies in a general way, and before entirely leaving the subject of variations in presses, it will be well to show by illustrations a few of the most common methods of fastening dies to the beds and rams respectively of the presses in which they are to be used. Some of these varying methods are equally good, but an important point with the user of such tools is to arrange for interchangeability to the greatest possible extent—not only that given dies may fit as many presses as possible as far as the kind and size thereof will permit, but especially that the hundreds of dies which he very probably has on his shelves (either actually or in prospect) may, as many as may be, fit in common a given press. Too much importance cannot be attached to the attainment of a strict system of uniformity in these fastenings so that certain dies can be quickly taken out of a press and others substituted, but also that there may be as few changes as possible in the adjustment of the press itself.

Bolsters.

In Fig. 47 is shown, in vertical axial cross section, a bolster, B, on which is fastened by tap bolts screwed into the same a lower die, L, it being understood that this bolster is, as usual, simply a flat plate bolted or otherwise secured to the bed of the press to which it belongs in the customary way—such bolsters being generally furnished by the press makers, either as a standard part thereof or especially to order. They often have a hole of some size and shape through them, as in Fig. 47, but are sometimes solid, as in Figs. 48 and 54. The general object of a bolster is to occupy some of the spare room up and down which is usually allowed in case extra high dies should be required for some special purpose, and also to partly cover up and bridge over the large hole which is usually made through a press bed, that work of a maximum size may sometimes be dropped through. Both of these objects are obviously to enable smaller and cheaper lower dies to be used for average work than would be the case were each die required to be thick enough and to have its flange or plate F, Fig. 47, spread out far enough to reach the bed bolts of the press which usually secure the bolster. In the same figure R is the lower part of a press ram, in which is inserted the upper die U, it being shown in this case with a tapering shank, S. This drives tightly into the socket of said ram and is prevented from slipping out by a set screw, which, for better security, is usually made with a point countersunk into the shank. To save complication, these dies are shown perfectly flat upon the faces which come together, and in this shape may be regarded as flattening dies, such as are frequently used for straightening and compressing small articles. Almost any variety of dies can obviously be secured by this and the other methods to be described.

Securing Dies.

Fig. 48 shows shank of die U cylindrical instead of conical. In this case the set screw does not need, necessarily, to be countersunk therein. The top end of shank at x is shown as having a bearing against top of ram hole, as well as the top surface of the die proper at y having its bearing upon the bottom of ram, it being better in all cases to have as much contact of solid metal as possible, to carry the heavy compressive stresses incident to all work of this kind. The bolster B is shown with a truss or boss, z, projecting below its bottom surface and extending downward into the bed of press. Such trussed bolsters are often useful for heavy work that happens to be concentrated near the center. In this case the lower die L is shown fastened by tail clamps C, C', the latter being of a crude form often used, where a piece of bar iron is simply bent at right angles and a bolt hole is thrown at it, so to speak, almost anywhere, instead of being put as close to the die as possible. Such a construction not only enables the clamp to bend down, but loses a good deal of the leverage that may be gained by arranging the proportions as in clamp C, where the bolt is put near the die. This clamp is of better design for withstanding bending strains, being thickened at the bolt hole. It is also rounded upon its lower surfaces at each end, and provided with a spherical headed screw (sunk below the surfaces out of the way of work catching against it), all of which allows it to accommodate itself to die plates of somewhat varying thicknesses.

In Fig. 49 is shown a bolster and ram into each of which the dies are screwed, being revolved by a straight wrench in holes h h', or by making the dies polygonal in shape or otherwise. Oftentimes with shanks of this kind the die U is made higher, as in Fig. 50, with a squared or hexagonal portion to the shank at s'. This construction is very common with round dies of small size, such as are used for can making, &c.

In Fig. 51 is shown a horizontal cross section, at a point just below x, of a ram like those in Figs. 47 and 48, the common form of dovetail slide bearings being embodied. This, however, is sometimes varied to some of the other forms shown in Figs. 15 to 20 inclusive. Incidentally a flange, f' f' (shown also in Fig. 54), is embodied in this ram, although it might be omitted as far as the other features described are concerned. In Fig. 52 is shown a similar section of a ram fitted with a separate clamp, as in Fig. 55, but with tap bolts to pinch it tightly upon die shank when inserted in the round hole, or punch socket, shown. In Fig. 53 is shown a modification of the latter form where the hole or socket is of rectangular form, set diagonally, the clamp being in this case mounted upon studs and tightened by nuts running thereon. This is perhaps, upon the whole, the best of all methods for holding shanks, especially when the socket is chambered out at the top, as at x, Fig. 55, so that if desired the shank can have a flange or projection entering into this chamber, and thus be held against any downward pull caused by stripping, &c. Such a socket will at the same time hold flangeless shanks just as well, and will accommodate those of round, round slightly flattened, octagonal or square sections. Furthermore the size of these shanks need not be accurate, as the clamp can be screwed up to various points in its path so as to grasp sizes of somewhat varying diameters.

Fig. 54 shows at L an extra large and heavy lower die, intended to be bolted directly to press bed without a bolster, also an upper die which is perfectly flat on the top and is secured to ram R by tap bolts through flanges f' f' (shown also in top view at Fig. 51) which are provided thereon. This is an excellent method for large cutting dies which might slightly shift in a rotary direction, on a vertical axis, if fastened with a shank only. Sometimes, however, they are secured with both shank and tap bolts.

In Fig. 55 is shown a bolster, B, to which is fastened a chuck, C', by means of countersunk tap bolts, although it might be fastened in various other ways, or might even be a part of the bolster itself, as in the next figure. In this chuck is secured a small cylindrical disk or ring shaped die, L, by means of a set screw. This is a common form, especially where there happens to be a large number of small dies which are of the same size outside, it evidently being much cheaper to mount them all in a common chuck in this way than to provide each one separately with a plate of its own. At C is shown an upper chuck, secured in the ram R by the method previously mentioned in discussing Fig. 53, although such a chuck may be mounted according to any of the systems above described. It is shown that upper die U is secured by a pointed set screw entering its shank, which latter, however, might be either tapering, as in Fig. 47, or screwed, as in Fig. 49. The same reasons in favor of the chuck system apply here as have just been mentioned for the lower die.

In Fig. 56 is shown another chuck system in common use, where the lower die L is dovetailed into the chuck B, which in this case is shown as made in one piece with the bolster, although it evidently might be separate, as in Fig. 55. The upper die U is shown as secured to the ram by the same dovetailed method, although when such dies are small they are sometimes dovetailed to an upper chuck, which is fastened to the ram by any of the methods shown. As here given, these dies are gripped by a wedge shaped gib, W, and also by set screws bearing thereupon. These set screws are, however, generally omitted, dependence being placed upon the wedge alone. In some cases the wedge is omitted, the set screws alone doing the work. In Fig. 57 is shown at B another form of bolster chuck, which is also represented in top view at Fig. 58. In this case the dies fit loosely inside of an upwardly projecting ring upon the chuck (or its substitute, four or three separate lugs) carrying the set screws shown. Such a die may be varied in position by running each set screw in or out to a more or less amount. It is one of the oldest methods for gripping dies, and is still used in many cases, but more especially upon drop presses where the die is solid and heavy and there is no other method provided for adjusting it laterally in place. It is, however, very objectionable for thin, ring shaped dies for accurate cutting or forming work, as the die itself is generally sprung more or less out of its normal shape by the pressure of the screws. In this case the upper chuck is shown as a shank, provided with an enlarged screw thread at its lower end, upon which a gland, g, is screwed. The

gland forces the upper die U upward by means of its conical head, and at the same time holds it rigidly in lateral direction. This form is much used for round punching work not exceeding 2 inches or 3 inches in diameter, and is very convenient and cheap, as the punches themselves, which have to be frequently renewed, are of the simplest possible form.

In Fig. 59 is shown a pair of shear blades, the lower one, L, fastened to a chuck, C', or in some cases to a bolster of similar shape, or in still other cases to the bed of the press itself, as made especially to receive it. At U is shown the upper blade, fastened directly to the ram, although in some cases an upper chuck is used. Two ordinary methods of fastening are shown, the upper one consisting of tap bolts

PRESS WORKING OF SHEET METALS.

tapped into the blade itself, and the lower one of countersunk screws through the blade. In some cases such screws are made longer and mounted with nuts, instead of screwing directly into the chuck.

At Fig. 60 is shown one of the common methods of fastening double action dies, for drawn work, to the ram of a double action press, R, which is usually provided with projecting flanges through which tap bolts run down into

In Fig. 61 is shown a die not guided by a tenon, but resting with its flat surface against ram R, being secured by sliding hook headed clamps. The inner die U' is screwed into the plunger, the same as in Fig. 49, and the outer die is supposed to find i's own position before being clamped to place. In Fig. 62 is shown the same arrangement as regards plunger, but with a threaded socket in ram, into which upper die is screwed. Sometimes a chuck, the upper part of which is fitted to ram in the same manner as is the die itself in Figs. 60 or 61, is used, thus getting the advantage of one chuck which will answer for several small dies. The lower dies are not shown in the last three figures mentioned, as they are fastened by some of the various methods shown for single action dies.

dies) capability of revolving the dies about their vertical axis to various desired positions in the ram or upper chuck and below, either directly upon the bolster or by revolving the bolster itself, or any lower chuck that may be used. 4. Interchangeability, as previously referred to. 5. Cheapness of design in one or both dies. There are in common use various methods besides those shown, which, however, will give a general idea of the most usual methods

PRESS WORKING OF SHEET METALS.

the flanged upper die U. As shown, this die is centered by a tenon projecting upward into the ram, the bolts being somewhat loose in their holes. The inner upper die (sometimes called a drawing punch) U' is shown as fitting and guided by the interior of the die U. Its shank at *s* is shown as fitting loosely in plunger P of press, so that if there are any inaccuracies due to wear or other causes, it may be rigidly kept in alignment by the die itself. A common method of holding U' from dropping out of plunger embodies a small bolt or other device not here shown, engaging in an annular groove running around *s* near its upper end.

The fastenings for upper and lower dies, as shown in the various pictures, do not necessarily go together respectively, as, for instance, the lower die in Fig. 47 might accompany the upper die in Fig. 48 or 49, &c.; and almost any of them could be freely changed about at will. Hereafter in this treatise the simple form of upper and lower dies shown in Fig. 48, each consisting of a small cylinder surmounting a large one, will be used, wherever suitable, as a conventional diagram representing a pair of dies.

Accuracy and Durability of Dies.

In making or purchasing dies, after considering what general mechanical

forms as above mentioned are best suited to his case, the die user should pay especial attention to getting the proper —not necessarily high—degree of accuracy and durability to suit his particular work. In some cases the accuracy must be very great, as, for instance, where certain pieces of work produced by various dies must assemble together and properly fit each other. In this case durability of certain working surfaces is very necessary in order that the sizes dependent thereon should be maintained as nearly uniform as possible. In other cases accuracy is not necessary, as, for instance, with various kinds of ornamental work, where mere appearance is the chief desideratum. Such dies may, perhaps, be required to have certain surfaces durable for the sake of maintaining the proper artistic effect or of avoiding wrinkles, &c. In other cases, however, there may not be any good reason for special durability, except avoidance of too frequent repairs or renewals. How frequent is a matter which depends wholly upon the required production. If, for example, only 1000 pieces of a certain soft brass ornament are wanted in a year, as is the case in some gas fixture manufactories, it would be foolish to make accurate hardened steel dies, because dies of the softest, cheapest material would run without any apparent wear for the hour or two required to make this quantity.

If, on the other hand, these dies were required to run every day and all day, making many millions of pieces each year, then the greater the first cost, with its consequent durability, the cheaper as a rule the dies would be in the long run.

In Figs. 63, 64 and 65 are shown perspective views of various lower chucks. In Figs. 66, 67, 68, 69, 70 and 71 certain forms of fruit can dies are pictured, this whole group, as well as the above mentioned chucks, being assembled at random from cuts in the catalogues of various die manufacturers. They are given here simply to show some of the designs in practical use—not necessarily as things of beauty and joys forever.

In Fig. 72 is shown in one group a complete set of dies for manufacturing such parts as could be made with dies of a certain design of lantern, used by one of our large railway companies. They are given merely as an illustration of the appearance such tools may assume in practice, and to give an idea to the uninitiated of the large quantity of dies required to produce a comparatively simple looking article. Such a group represents a great many hundreds of dollars for the actual cost of the dies included therein. Each pair of dies, nevertheless, will cheaply produce millions upon millions of pieces, all practically alike.

Materials.

Having analyzed to some extent the tools used in the art of sheet metal working, of which we are treating, it may now be well to glance at the general nature of the materials worked upon by these tools. Although my title speaks of sheet metals as the general name for these materials, I must qualify the term somewhat by including certain forms of bar metals. This is not really changing the subject, for it is difficult to make a logical distinction between a sheet and a bar; and, furthermore, as a practical matter, the same presses and dies are often called upon to work both of these forms. Neither will the remarks to follow in the various succeeding chapters always limit themselves entirely to metals, as in some cases other certain non-metallic articles in the forms of sheets and bars are treated by the presses and dies in question in an exactly similar manner to the metallic ones.

In Figs. 73 74, 75 and 76 are shown a few of the various forms of bar metal in common use, their cross sections being circular, semi-circular and rectangular respectively. In Fig. 77 is shown a sheet of tin plate and in Fig. 78 a roll of sheet brass. These latter, and in fact all sheet metals, are obviously but very thin, wide bars, and there is, therefore, no vital distinction between them and any other flat bar; like Fig. 76, the difference being only in degree and not in kind. As a practical matter we shall find that such bars as are here shown (and others) are frequently worked in the same machinery as are the sheets, which differ from them only by being thinner and wider in their general proportions.

The commercial names of these materials are too well known to need much comment here. In this country and in Great Britain the English inch, and the fractions thereof in common use, are, I believe, always used to designate bar iron, steel and copper, as well as the larger sizes of brass. Thus, for instance, bar iron is known as ¾-inch round, 1-inch square, 4 x ½ inch, &c. The wider bars, usually called plates, such as are used for boiler making, shipbuilding, &c., are also usually designated by their width and thickness in inches. When, however, round bars become so small as to be called wire, which is usually under ½ inch in dismeter and of a length sufficient to coil, and when sheets become too thin to be described by ordinary inch fractions, then trouble commences. This trouble arises from the innate foolishness of the human heart, which cleaves to that which is old, no matter how absurd, and hesitates long about adopting the new, however permeated with common sense.

Gauges.

These remarks refer to the vexed question of the so-called wire gauges, which might occupy the whole of my available space were I disposed to go into it. It is enough to say that the various dozen or two gauges in common use are all ridiculous and are founded upon no scientific system whatever. They are, moreover, extremely inconvenient and are somewhat confusing on account of the smaller numbers representing the thicker metals. I will not here attempt to designate the actual thicknesses represented by the numerous host of gauges, such as old English, Holtzapfel's, Lancashire, new English, imperial standard, Prentice, Trenton, Washburn, music wire, rivet, hoop iron, machine screw, and, worst of all, the last absurdity recently adopted by our American Congress wherein the lowest number, for the thickest metal, is written with seven ciphers in a row. How these are pronounced I do not know. Neither can I imagine who will ever take the trouble to count them. It will be sufficient here to give the value in thousandths of an inch of three gauges, which are in the vast majority of cases in actual practical use, viz.: 1. The Birmingham or Stubs' gauge which is almost always meant when sheet iron or steel, or galvanized sheet iron, or iron wire is referred to and sometimes also brass and copper wire. 2. The American or Brown & Sharpe gauge, which is usually meant when sheet brass or copper is spoken of and sometimes wire of these materials also. 3. The so-called zinc gauge, which may or may not be meant when that metal is referred to by number. These measurements will be found in the table below, but it must be remembered that there is no certainty, when anybody orders a certain number of metal, as to what gauge he means; and, furthermore, that the notches of the so-called wire gauges in common use are continually wearing and becoming all the time more inaccurate than they were at first; and also that people who sell metals usually work with such worn gauges.

Besides the two distinct names given in the table above for the Birmingham gauge, it is often spoken of as B. W. G., and also as the English gauge or the English standard wire gauge. These latter names are evidently misnomers, because there are several other English gauges. In Fig. 80 this gauge is shown, full size, as often made, its thickness being in the neighborhood of ⅛ inch. It will be noticed that its misleading name is stamped upon it. In Fig. 79 is shown the American gauge, whose accuracy, when new, can be depended upon if stamped with the maker's name, as shown in cut. No picture is here given of a zinc gauge, as it does not seem to be an article readily procurable in the market, and probably does not often have its portrait taken.

In addition to the "pure mongrel" methods of measuring just referred to there are other interesting systems in common use. One of these is that employed by makers and users of tin plate, where the thickness of the sheets is defined with a delightful uncertainty by the use of the word "taggets" to denote a thickness of anywhere from 0.004 inch to 0.008 inch, averaging, perhaps, 0.006 inch; of "IC" to denote from 0.010 inch to 0.014 inch, averaging about 0.012 inch; of "IX" to denote from 0.013 inch to 0.017, averaging about 0 015 inch; of "IXX" to denote from 0.015 inch to 0.019 inch, averaging about 0 017 inch, &c. There is no definite value that can be attached to any of these terms, and

such alleged values as they have overlap each other in a number of cases, as will be seen by the instances given above. Neither do the gauge makers supply us with any tools whereby sheets designated by these mysterious symbols may be measured. If they did the gauges would probably have to be made of india rubber.

Another yet more foolish method of defining the thickness of sheet metal is to specify the weight in pounds or ounces per some unit of surface area, as so many ounces per square foot, &c. The solving of such puzzles as are involved in measuring operations of this kind requires either long experience or a mathematical mind of a high order.

Under existing circumstances the only sensible method for measuring sheet metals and wire is by a micrometer caliper such as is easily obtained in open market in the form shown in Fig. 81, or in a yet more convenient form, as far as thin metals are concerned, as depicted in side view in Fig. 82, and top view in Fig. 83. This is a design contrived by the writer for a gauge to be carried in the vest pocket, and to be instantly read without the calculation required in Fig. 82. It is not patented, and it is to be hoped that some gauge maker will recognize its good points, if it has any, and put it upon the market.

The subject of establishing one gauge which shall be universally used, in all English speaking countries at any rate, is now exciting considerable attention in the various engineering societies, and is under consideration in a committee recently appointed for the purpose by the A. S. M. E. The writer has for some years past, in various publications, earnestly urged the adoption of a gauge which shall simply agree, as far as it goes, with the micrometers just mentioned. In brief, it would consist for each particular trade or business of a plate containing such notches as were most convenient for that trade, each one being known by that number representing the number of thousandths of an inch which measured it. Thus the notches in any given gauge could be of any size required, and as few in number as possible. The various gauges made would always agree where they happened to contain similar numbers, and yet the largest latitude could be used in accommodating them to their special purposes. The writer recommends that this gauge be of an elliptical shape, to distinguish it from the various round and octagonal shapes now on the market, and that some enterprising manufacturer shall aid in introducing so useful an engineering tool by the simple process of introducing it. There is no question but what it would take care of itself as far as staying introduced was concerned. It would be well to have all forms of this gauge contain some simple symbol, such, for instance, as M G, meaning thousandths gauge, by which name it might appropriately be known.

The last of the students' gatherings which have enlivened the course of training this year at the New York Trade School was held on Tuesday evening. Addresses were made by Walter Reid, ex-president of the Master Painters' Association, and by John Mitchell, vice-president of the National Association of Master Plumbers. A number of prominent tradesmen and a large attendance of the students formed an attentive audience.

There are two manual training schools in operation in Japan.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

Higgins & Co., 379 Lexington avenue, New York, installed one of the first of the new No. 377 Richmond sectional steam heaters in the large club house of the Bay Ridge Club, at Bay Ridge, L. I. The circuit system was employed and the plant has been successfully tested.

G. S. Blodgett Company, Burlington, Vt., have nearly completed the plumbing and heating of the barracks, guard house and hospital at Fort Ethan Allen, near Burlington. A Dunning steam boiler will be used in the barracks, and an American Boiler Company's Perfect hot water heater in the hospital.

Benjamin F. Shaw, Wilmington, Del., hss received the contract for the plumbing and steam fitting to be done at Gordon Heights by the Wilmington Steamboat Company.

Architect Eisenman of Cleveland, Ohio, has about completed plans and specifications for the steam heating, wiring, piping, plastering, &c., of the State Masonic Home at Springfield. These plans will be submitted to the trustees next week, and the contracts let by April 1.

E. Baggot, 169–171 Adams street, Chicago, is to furnish the plumbing, sewerage and gas fitting for the residence of F. F. Kinney, 779 Jackson Boulevard.

The Kelly & Jones Company, 48–52 North Clinton street, Chicago, have taken the contract for the steam heating plant in the Garfield Building, Cleveland, Ohio. This building is 11 stories in hight, has a frontage of 170 feet on Bond street and 71 feet on Euclid avenue.

The Smith & Anthony Stove Company, 217 Lake street, Chicago, are to furnish 400 "Fig. II" Sanitas brass traps for the Marquette Building, Adams and Dearborn streets.

Among the contracts recently taken for steam heating by Cook & Chick, 253 Kinzie street, Chicago, can be mentioned the following: The 16 flat building of Richard Curran, 4450 St. Lawrence avenue; store and flat building of T. M. Heaney, 256–258 Kinzie street; residence of H. F. Thoma, Champlain avenue and Fiftieth street, and residences of W. F. Olin and Mrs. Mary Brabon, Edgewater, Ill.

David Ahern & Son, Fond du Lac, Wis., are to furnish Gurney heaters and necessary radiation for hot water heating plants in the Saint Mary's Academy, Saint Mary's, Wis., and the Holy Angel's Church, West Bend, Wis.

John Trainor of Linden avenue and Mosher street, Baltimore, Md , is doing the plumbing in the new Builders' Exchange building in that city. He is using 25 Acme syphon jet closets with quartered oak tanks and seats, five Demorest porcelain lined closets with oak tanks, and 50 Boston lavatory wash basins in pink Tennessee marble slabs. All fixtures are locally vented to a heated stack, and countersunk Tennnessee marble floor slabs are used for all fixtures, safety wastes, &c.

The Baker & Smith Company, 193–197 Van Buren street, Chicago, are to install a hot water heating plant in the residence of E. Frankenthal, Michigan avenue and Thirty-third street.

E. Baggot, 169-171 Adams street, Chicago, is to supply additional plumbing in the Wollensak Building, Washington and Clinton streets.

Chas. H. Graves, 62 North Clark street, Chicago, has the contract for steam heating in the flat building of Adam Zaska, Troy street, near Twelfth. A Florida boiler will be used.

F. W. Lamb & Co., 258 Michigan street, Chicago, are placing a steam heating plant in the apartment building of A. E. Kent & Son, Calumet avenue and Forty-third street.

Peck Bros. & Co., 259 Wabash avenue, Chicago, have just furnished their Boyd lavatories, triple jet closets and porcelain baths for L. A. Norton's residence, Austin, Ill. Also the complete plumbing specialties in L. A. Mick's apartment building, Forty-fifth street and Wright avenue.

Calvin K. Austin will build a three-story apartment house at a cost of $15,000, at 1633 Roscoe street, Chicago, to be heated by hot water and supplied with gas ranges. The bathrooms will be laid in tile.

Hynes Bros. will erect a five-story apartment house, 50 x 80 feet, at 3641 State street, Chicago, at a cost of $30,000, to be heated by steam.

Peck Bros. & Co., 259 Wabash avenue, Chicago, are to furnish the plumbing goods used in the flat building 3034 Portland avenue, E. D. Connor, plumber; P. Ryan's building, 409 North Clark street, M. A. Mandable, plumber. Also in the residence of A. R. Grisevold, Princeton, Ill.

H. E. Fry & Bro. Jacksonville, Ill., have secured the contract for the hot water heating apparatus in the residence of R. F. Cassell. E. E. Butterfield, Winchester, Ill., has the contract for heating the residence of G. W. Owings by hot water. J. B. Kingsburry & Co., Osage, Iowa, received the contract for heating J. A. Smith's residence by hot water. Boilers of the American Boiler Company's manufacture will be used in filling the above contracts.

An Industrial Exhibition of Engineering and Mining Inventions and Manufactures is to be held in April and May in Birmingham, England.

An Ohio crank, Coxey by name, announces that he will lead an army of 10,000 unemployed Americans to Washington about May 1, to demand legislation for the relief of the people.

The question of the disposal of the schoolship St. Mary's, hitherto maintained by the City of New York, is again under consideration. The various chambers of Commerce and Boards of Trade throughout the State are in favor of transferring the training vessel to the State authorities, and resolutions to this effect have been largely adopted.

Edison has perfected his latest invention, the kinetoscope, an instrument by which a series of pictures can be rapidly taken of a person or object in motion, in what is practically a single picture. He has taken some perfect plates with this apparatus, which promises to mark a new era in photography.

STOVE TRADE NOTES.

The Philadelphia Stove Trade.

The stove trade in this section is extremely quiet, but the fact that it is between seasons accounts for a good deal of the prevailing dullness. While, of course, it is too early to expect any business in heating stoves, still at this season of the year cook stoves and ranges should be in moderate demand and a fair business done. It is not the case, however, this season, and orders are limited in size and small in quantity. Dealers are buying only to an extent sufficient to keep up a fairly representative stock, preferring to cover sales by small orders, and reasonably assuming that there will be no trouble in obtaining prompt shipments. Furnaces are in little better demand, but orders are mostly for future shipment and for buildings in course of construction. Orders from retailers are light and cover only immediate requirements.

There is a fair demand for summer goods, but the volume of business is not so large as might reasonably be expected for the time of year. Most of the large orders are yet to be placed and the season will necessarily be a little late, but a good business is looked for. Gas stoves and ranges will be in large demand presently, judging from the number of inquiries made in regard to them. This is mostly due to local conditions. The city of Philadelphia is now supplying gas at $1 per 1000 feet, therefore it is natural that the adaptability of gas for heating and cooking purposes should create a strong demand for gas goods.

There seems to be a difficulty experienced by nearly all manufacturers in the matter of making collections. It is freely stated that collections are now fully as hard to make as during the financial panic of last fall. It is fair to suppose that this condition in a measure explains the laxity on the part of retailers in placing orders for seasonable requirements. One of the largest houses in the trade here makes the statement that 25 per cent. of the paper accepted to cover last season's business was renewed in some form. A good deal of money is locked up in the building trade. Builders have not been able to turn over their work, and consequently manufacturers and dealers furnishing heaters have to wait for their money.

The prospects for future trade are good, stocks being low on every hand, excepting, perhaps, the stocks held by one or two manufacturers who ran their foundries last summer and fall, without curtailment of production. With the settlement of the tariff question and a resumption of business there is every probability of a good year's business being done.

Cupola Management.*—VII.

BY DR EDWARD KIRK.

Blast.

Before the blast is put on the tuyere doors are all tightly closed and luted to prevent the escape of any of the blast during the heat, and they should be examined from time to time to see that the luting has not blown out and the blast is escaping. The blower is speeded up to the full speed at once, and the full volume of blast given the cupola from the start. The old way of putting on the blast light and increasing or decreasing the blast at different stages of the heat has been abandoned by practical foundrymen, and the cupola is given the same blast from the beginning to the end of the heat. This is the only way good melting can be done in a cupola charged in the way before described. If the cupola does not work properly remedy the evil by changing the charges, but never vary the blast in different parts of a heat to improve the melting.

When the blast is first put on it is indicated by a rush of blast from the tap hole and at the charging door by a volume of dust passing up the stack. Then follows a bluish colored gas which bursts into a bluish flame as the stock settles, changing to a yellowish hot flame as the stock sinks still lower. If the stock is kept up level with the charging door in a cupola of good hight the gas does not ignite and it is the aim of the chargers to keep the stock up to this point until they are through charging. When the blast is shut off from a cupola for any cause or at the end of the heat before the bottom is dropped, one or more of the tuyere doors are at once opened to prevent gas from the cupola passing into the blast pipe, where it is liable to explode and destroy the pipe.

The full consideration of the blast for a cupola would take up more space than I care to give to the subject in this article and would lead my readers too far from the subject of working a cupola. I shall leave the subject for a more full consideration under another heading.

Melting.

Melting begins in a cupola soon after the blast is put on, and the exact length of time is indicated by the appearance of molten iron at the tap hole. When the iron is charged two or three hours before the blast goes on, and the bed is not too high, iron flows from the tap hole in from three to six minutes after the blast is on. When the iron is charged and the blast put on, as soon as the cupola is filled iron appears at the tap hole in from 15 to 20 minutes, if the bed is not too high. When the bed is too high iron melts when the surplus fuel is burned up and permits it to come down to the melting point, and it is very uncertain when melting will begin; and it is generally from half an hour to an hour before any molten iron appears at the tap hole. If iron does appear at the tap hole within 15 or 20 minutes after the blast is on, the bed is either too high or the fire has not been properly lit, and the bed is not doing its work properly.

Foundrymen differ as to the time for charging the iron before the blast is put on. Some claim fuel is wasted by lighting the fire early and charging the iron two or three hours before the blast is put on, while others claim fuel and power are only wasted by putting on the blast as soon as the iron is charged. I have melted iron in both ways, and I prefer to charge the iron from two to three hours before the blast is put on, except when the cupola has a very strong draft that cannot be shut off, as is sometimes the case when there is no slide in the blast pipe for shutting off the blast, and as air is supplied to the cupola through the pipe. When iron is charged and the cupola filled to the charging door with fuel and iron, and the draft shut off from the cupola, the combustion of fuel in the bed is very, light and the heat that rises from it is utilized in heating the first charge of iron. When the blast is put on, this charge of iron is ready to melt, and iron comes down in a few minutes. When the blast is put on as soon as the iron is charged the iron is cold, and time is required to heat it before it will melt, and the blower must be run 15 or 20 minutes before iron appears at the tap hole, and the first charge melts slower than when the iron has been heated before the blast is put on.

I think the best way is to put on the blast about two hours after the charging begins. When the blast goes on, the tap hole is open and is left open until the iron melts and runs hot and fluid from it. From 10 to 20 pounds are generally permitted to run from the spout to the floor to warm the spout and insure the iron being sufficiently hot to not chill in the tap hole after stopping in. The first iron melted is always chilled and hardened to some extent by the dampness of the sand bottom and spout, and when the work is light and poured with hand ladles, a small tap of a few ladles is made in a few minutes after stopping in and the iron used for warming the ladles and then poured into the pig bed or some chunks. In some foundries the cupola is not stopped in at all after the iron comes down. The first iron is used to warm the ladles, and as soon as the iron is hot enough for the work the molders begin pouring it. I recently ran off a heat of 31 tons in this way from a cupola for hand ladle work without using a single bod for stopping in.

When the iron is handled in large ladles a tap is not made until a sufficient quantity is melted to fill a ladle or there is a sufficient body of iron in the cupola to insure it not chilling in the bottom of a large ladle before another tap is made. When the blast blows out at the tap hole after a tap is made it indi-

* Copyrighted, 1894, by Dr. Edward Kirk.

cates that the melted iron is all out of the cupola or the tap hole is too large, and the cupola should be stopped in until iron collects in the bottom, or the size of the tap hole should be reduced to prevent the escape of the blast. The size of the tap hole is reduced when it gets too large to run a continuous stream without blowing out, by stopping in with a bod of stiff clay and sand that will not cut, and as soon as the bod is set cutting a new tap hole through the bod with the tap bar. Iron should be melted hot and fast, and iron should never be drawn from a cupola for any kind of foundry work that is not hot and fluid enough to run stove plate or other light castings. Iron is not burned in a cupola by melting it hot and fast, but it is burned and hardened by melting it too high in the cupola and melting it slow and dull.

Nothing is gained by holding molten iron in a cupola to keep it hot, for it can be kept as hot in a ladle as in a cupola, and iron should be drawn from a cupola as fast as melted or as fast as it can be handled in pouring the work. If I were running a foundry I should never stop in the cupola except to get enough iron to give a gang of men a hand ladle full all around, or to remove a large ladle from the spout. When the cupola is very small and melts slowly it is sometimes necessary to stop in and collect iron in the cupola, but it is not necessary to stop in a large cupola for this purpose. If the iron is all poured with hand ladles the men should be divided into gangs, with only enough men in each gang to take away the iron as fast as melted. If this is not done and there is a large number of men the ladles get so cold between catches that they chill the iron before it can be poured, and the melter is blamed for not making hot iron.

The flow of iron from the tap hole indicates how the cupola is melting If it has been properly charged the flow will be even in quantity and temperature through the heat, except in a very long heat, when the stream will get smaller and the cupola not melt so fast toward the end of the heat. When too much fuel is used the iron melts slow and grows dull as the heat progresses. When the charges of iron are too heavy the iron is not of an even temperature through the heat, but is dull at the latter end of every charge and hot at the first of the next charge. When the charges of fuel are too heavy the iron melts very slowly at the beginning of each charge and fast at the latter end, and if the charges of iron are also too heavy the iron is dull at the latter end of the charge. If the cupola melts unevenly it is not being properly worked, and the mode of charging should be changed until it does melt evenly from the beginning to the end of the heat.

The Jesse Orr Memorial.

The memorial of the late Jesse Orr ordered by the National Association of Stove Manufacturers has just been engrossed by J. Vreeland Haring, Room 289, Stewart Building, New York City, where it was the privilege during the past week of a representative of *The Metal Worker* to examine it. The memorial is mounted in a handsome gilt frame 33 x 40 inches in size. The wording of the memorial is in script, round hand and Old English, and is admirably and artistically executed. The heading, consisting of the name of the association of which Mr. Orr was president at the time of his death, is in block letters with three banks of shading, and ornamented with scroll work in white. Directly below this is the likeness of Mr. Orr, done with pen and brush, and inclosed in a wreath of laurel. Underneath the picture, in Chinese white on a dark panel, appear the words "Jesse Orr," and at the right and left of the picture in script letters are portions of the memorial, presented at the meeting of the National Association held in Chicago last June. The matter is artistically displayed and is embellished with rococco ornamentation. The memorial is signed by the committee, consisting of W. H. Pfahler, Grange Sard and C. T. Prizer.

Acorn Stoves.

Rathbone, Sard & Co. of Albany and Chicago have just issued some circulars referring to their new goods. One is entitled "Acorn Ranges." It illustrates and describes the National Acorn six-hole range for soft coal and for hard coal, special patterns being made for each, in four sizes and all styles; the Magnet Acorn six hole range for soft or hard coal or wood, in four sizes, with square top or reservoir; the Duplex Acorn four-hole range for soft or hard coal or wood, in four sizes and square top or with reservoir; the Citizen, low priced range, for any fuel, in three sizes for five hole and two sizes for six hole; the Eureka, low priced four-hole range, for any fuel, in two sizes; the King Acorn, six hole wood range, in four sizes, with reservoir or square top; the Pacific Acorn, medium priced six-hole wood range, in three sizes, square top or with reservoir, and the Prince Acorn, four-hole wood range, in four sizes, with square top or reservoir.

A second circular is devoted to new cooking stoves, showing four patterns for coal and four for wood only, all being separate and distinct, and so graded in price and style that they form a complete line. They comprise the new Iron Acorn, for soft coal, in four sizes; the Standard Acorn, for soft coal, in four sizes; the Live Acorn, for coal or wood, in seven sizes; the Economist, for coal or wood, in four sizes; the Regal Acorn, for wood only, in four sizes; the Beech Acorn, for wood only, in six sizes; the New Loyal Cook, for wood only, in six sizes, and the Columbia, low priced cook, for wood only, in six sizes. Of these, the Standard Acorn stove is true to its name in the matter of its decorations, acorns standing out as a prominent feature, being shown not only in nickel panels, but also in the molded work.

The third circular relates solely to vapor stoves, giving particulars regarding the company's line for 1894. They offer a larger and more complete assortment than ever before, including the Tropic new process, the Tropic hot generating, the Tropic junior low and the Tropic junior high stoves. The new process stove has a sheet steel frame, handsomely japanned and decorated nickel plated mantel shelf, nickel panels and name plate, and is provided with an oven step. The tank is made in two sections to equalize the flow of gasolene and avoid uneven pressure as the tank becomes partly emptied. The needle points are of German silver and are non corrosive. Cylinder drums are of brass, with cast iron bottoms, which will not corrode or rust through. These stoves are made with either two or three burners and step. The hot generating vapor stove is the company's standard stove, of which many thousands are now in use. It is the only vapor stove with a removable cartridge in the stand pipe, covered by the company's patent and enabling the stove to be easily cleaned. It is made with a steel frame, folding oven shelf, lay down tank, hot blast tubular burner caps, handsomely decorated table and large nickel dial plate, and either two or three burners on top. The junior low stoves are made with one, two or three burners, and the junior high stoves with two or three burners.

ODD PLATES.

Stove manufacturers are looking forward with much interest to July and August of this year. Trade was so completely flattened during these months last year by the panic then prevailing that they naturally expect their records will show wonderful gains in the volume of business. Indications point to a good demand for stoves by that time, so that they are not likely to be disappointed. Panics do not occur two years in succession.

The March Brownback Stove Company, at Pottstown, Pa., resumed operations in their extensive foundry on Tuesday, March 6. The mounting department has been in continuous operation for some time past, and now the molding, finishing and other departments will be started up and run partly, if not full capacity.

Bergstrom Brothers & Co., proprietors of the Neenah Stove Works, Neenah, Wis., resumed operations on Monday, March 5, after being shut down since Christmas.

The Eclipse Stove Works of Mansfield, Ohio, have been putting in a new upright boiler, which is said to be the second one of its kind in use in that city. It is the patent of John Cahall of the Aultman-Taylor Company.

The Somerset Stove Foundry Company of Somerset, Mass., resumed operations last week after a shut down of over two months.

Cole & Cole of Omaha, Neb., expect, before the season is very far advanced, to be giving employment to a number of hands in the manufacture of their new air tight wood heater.

The Union Stove Works of 70 Beekman street, New York City, are the assignees of a patent granted February 20 to Reuben R. Finch and Thomas J. Hodgkins of Peekskill, N. Y., for a combined cooking range and gas stove. The range is provided with a boiler hole top, above which is a warming shelf supported by side brackets. The gas stove consists of two burners adapted to rest on the top of the range and is connected with the side brackets by means of links pinned to each of the ends of the gas stove. The arrangement is such that the latter may be swung up beneath the top shelf for the purpose of heating vessels placed thereon, or the burners may be used on top of the range for ordinary cooking operations. By this arrangement the gas stove is adapted for use in connection with the cooking functions of the range, or independent of it, as may be desired.

Superintendent Reilly of the Lebanon Stove Works of Lebanon, Pa., has resigned his position to accept a place with the Raymond & Campbell Mfg. Company of Middletown, Pa.

J. S. Patrick of the G. S. Blodgett Company, Burlington, Vt., has been calling on the Boston trade during the

past week in the interest of the Blodgett oven, and has placed a number of orders for a variety of goods used by his concern.

The John Torrey Mfg. Company, Portsmouth, N. H., manufacturers of Stovene, are represented in Boston by Mrs. E. T. Shaw, who is probably the first woman drummer to call on the stove trade in New England, although she is not without experience, having traveled in the West for another stove polish manufacturing concern last year. The trade accepts the innovation gracefully, and Mrs. Shaw seems to be making a favorable impression.

Josiah M. Read, 61 Blackstone street, Boston, the veteran manufacturer of the Read Regulating Check Damper, is at business again after quite a long period of sickness. Mr. Read will soon celebrate his 85th birthday, and is one of the oldest men connected with the trade in New England.

The Thomas, Roberts, Stevenson Company, Philadelphia, are inclosing in all of their envelopes used in correspondence a half tone engraving of their No. 68 Active Fortune range and testimonial letters on the merits of their Gauge Door ranges from Mrs. S. T. Rover of the Philadelphia Cooking School and L. A. Willis of the Baltimore Cooking School.

Custer & Richards of Bridgeton, N. J., have shipped a Valley Novelty range to a Belgian glassblower who returned from Bridgeton to his native country.

George M. Clark & Co., with office and factory at 149–161 Superior street, Chicago, Ill., send us a copy of their thirteenth annual greeting in the shape of an attractive catalogue of Jewel gas stoves. The line of these goods, we understand, is larger and better for 1894 than ever before, additions having been made to the No. 390 series of two large ranges, similar to Nos. 353 and 352; also three baking plates with broilers below. The manufacturers also state that the list price of Nos. 353, 352, 351 and 350 has been lowered. The goods embrace an extensive variety, all of which are illustrated and described in a manner to interest the dealer. The Jewel ranges are shown with and without waterback and with three or four burners in the top surface of the stove. Attention is given to Jewel step stoves, laundry stoves, table stoves, baking plates, tailors' iron heaters, wall ovens, the Jewel circulating water heater and connections of various kinds. An interesting feature of the work is an index giving also weights, size of connection pipe and telegraphic code words and prices.

The semi-annual meeting of the Vapor Stove Manufacturers was held early in the month at the Hollenden, in Cleveland, Ohio. The leading manufacturers of vapor goods were in attendance. The sessions were devoted to routine business.

Practically all of the Southeastern Massachusetts stove foundries have been idle for some weeks. Ordinarily at this season they have run on stock, but owing to the uncertainty of the outlook it was not thought advisable to pile up goods for future business. At Taunton, White, Warner & Co. started up on the 14th with a full complement of hands and some orders on their books, and the Taunton Iron Works Company resumed on the 13th. It is reported that the Weir Stove Company and O. G. Thomas will resume operations about April 1. An unusually large number of new styles in both ranges and parlor stoves are to be put on the market from this section for the fall trade.

The representatives of the Howard Furnace Company were summoned to the home office at Syracuse on Thursday and Friday of the past week for the second annual conference. After full consultation with the officers of the company they were entertained with a sumptuous banquet at the Yates House, which was opened by a brief address from the president, and terminated with a toast to the health and prosperity of the company. Those present were E. M. Moore, president; J. H Norton, vice-president; F. H. Moore, treasurer, and Lyman Norton, secretary; the resident officers at the home office, Messrs. Beers, Van Keuren and Ford of Syracuse, Mr. Tyler of Grand Rapids, Messrs. Healy and Stevens of the Boston office, and Mr. Wilkinson of the New York office. The occasion was one of great pleasure, and all returned to their respective duties with the determination to place the Howard furnace in the lead.

J. W. Van Cleave, manager of Buck's Stove & Range Company, St. Louis, was the recipient of a very handsome buck a few days since, which was presented to him by the traveling representatives of this house. The buck was shot in the forests of Newfoundland, and was exhibited in the World's Columbian Exposition, where it received much well merited praise. The head, with massive antlers, occupies a prominent position over the mantel in Mr. Van Cleave's office, while the hide does service as an office rug. The presentation came in the nature of a surprise to Mr. Van Cleave, and is highly appreciated by him. It is peculiarly appropriate, as all our readers are aware that the buck's head rising out of a body of water is the principal feature of the trade mark of the company.

The Peninsular Stove Company of Detriot, Mich., have brought out a new four-hole range, which is known as the Home Peninsular. It is intended for hard coal, coke, wood or natural gas, and is offered in four sizes. It has large square oven, which is not cut under the fire box, and the ventilation is referred to as being highly satisfactory. The range is made with large sheet flue, oval fire box, and fitted with duplex, draw center or flat grate, as may be ordered. The ornamentation is of an attractive character, a striking feature being the embellishment of the oven door. The company are booking sample orders, and from present indications the Home Peninsular is likely to prove very popular with the trade.

The Bussey McLeod Stove Company of Detroit, Mich., resumed operations on Thursday, March 15, with a force of nearly 250 hands; also the Chicago Stove Works, which is the company's Western plant, resumed at the same time, giving employment to a force of about 350 men.

The Durand Mfg. Company of Nedina, Ohio, have issued an interesting pamphlet of pocket size, in which attention is invited to what they designate as their Improved Kerosene Oil Queen, for which many claims are made. The company state that "combustion is effected with the aid of a round wick, but instead of the white flame from the wick, the burner is so constructed that the oil is vaporized at the edge of the wick and air supplied in proper places and quantities to make a clear blue flame of intense heat." The stove is made with two and three burners. The little pamphlet also illustrates and describes the company's Franklin heater, in which is an enlarged burner, making it powerful in operation. The device is light and mounted on casters, so that it may be readily moved from one room to another, making it especially desirable for the sick room.

The Standard Range Company of Evansville, Ind., have brought out a new line of high grade steel ranges, which are offered the trade under the name "Standard." The features incorporated are covered by letters patent, five in number. The Standard is fitted with oval fire pot, ventilated oven and draw center shaking grate, which may be removed or replaced without disturbing a bolt, screw or any part of the fire pot and without the use of a tool. The oven is ventilated, the air being thoroughly heated before entering the oven, after which it goes out through a gauze side and thence to the flue. The oven door kicker is of such a nature that the door may be opened or closed by a slight pressure of the foot downward or upward without taking the heel from the floor. The company state that they make all sizes of ranges from the smallest adapted for family use to the largest intended for hotels, restaurants, &c. The company have in contemplation a catalogue which will fully illustrate and describe their specialties, and which it is expected will soon be issued to the trade.

Southard, Robertson & Co., Water street and Peck slip, New York City, are distributing to their friends blotting pads carrying advertising matter relative to the Waldorf ranges. These stoves, made both portable form and for brick work, have right or left hand fire box for horizontal or upright boilers, skeleton or full warming closet and sifting grate. The manufacturers refer to the ranges as satisfactory bakers, easily managed, always reliable and economical in the use of fuel.

We have received an assortment of advertising matter from the Michigan Stove Company, as specimens of the material they are now supplying to their customers. One of these is a lithographed letter head, suitable for a merchant handling hardware and stoves. The lithographic design is highly artistic, and the company furnish such stationery to their agents at very low prices. Next is a recipe from "Dr. Experience," who prescribes as a cure for that "tired feeling," induced by too hard work to sell goods, that "Garlands" should be taken up as a line, with brains and push, "to be well taken and tested before shaking." Then comes a pamphlet which is a veritable hard times piece of work. It is printed on coarse wrapping paper and tied with a tow thread. There are eight pages, and they are by no means covered with reading matter. The sentences are pointed, however, and cannot fail to enlist the attention of the reader. No reference to Garland stoves and ranges is made until the fifth page is reached, when points made earlier begin to be driven home. It is a unique pamphlet, of the kind not thrown into the waste basket before careful examination.

Crinnen, Sexton & Co. are now erecting a large addition to their stove plant on Erie street, Chicago. It is a

brick atructure consisting of six stories and a basement. The offices and sample room will be located on the first floor, while the remainder of the building will be used for storage. On the completion of the building the firm will transfer to it their offices, which are now located on Lake street. It is expected that the consolidation of offices and salesrooms with the manufacturing department will enable the firm to transact their business with much greater satisfaction to themselves and their customers. The business of this house has shown steady and sometimes rapid growth, and while they have in common with other manufacturers felt the effects of the depression in business, they are putting themselves in shape to handle a much larger trade whenever the times improve and stoves begin to move as they should.

The Detroit Stove Works have nearly completed their new warehouse at 2921 to 2929 Twenty-ninth street, Chicago. They are already beginning to remove from their present quarters at 269 and 271 South Canal street, and expect to be comfortably installed in the new location by April 15. The offices will be handsomely fitted up and every convenience will be introduced for the rapid dispatch of business. Their facilities will be greatly increased. The company have put on the market within the past month a new steel range, cabinet style, which is proving very popular, although it has been but a short time before the trade. It is well designed, ornamented profusely with nickel, provided with all the latest improvements, and is sold at a moderate price. They are making a new departure this year in taking up gas goods. Their first venture in this line will be a gas range, which will be ready shortly. It will no doubt be a fine piece of work to sustain the reputation of the company in the regular stove line. B. W. Dodson, vice president and Western manager, is now in California, enjoying a brief respite from business cares, to be gone for perhaps a month.

Rathbone, Sard & Co.'s stove foundry at Aurora, Ill., is running full time and has not been shut down during the past 12 months at any time except for a brief period when inventorying. Conditions have been such for the past year that the company have found it advantageous to concentrate their work at Aurora, instead of dividing it between the Aurora and Albany works. Thus the Aurora plant has been enabled to run full time, making Aurora one of the best towns for stove workmen in the country.

The Excelsior Steel Furnace Company, 36 Monroe street, Chicago, report an improved demand for furnace fittings and furnacemen's supplies. Their ready made stacks, elbows, boots and heat pipes are working their way into the favor of the trade, and will this year be used by many more furnacemen than ever before.

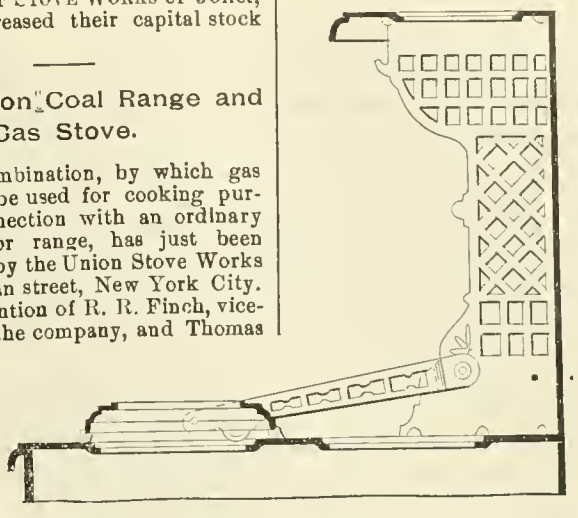
The Midland Steel Company of Muncie, Ind., for whom James W. Ross, 647 The Rookery, Chicago, is sales agent, are now making smooth sheet steel for stove bodies. These sheets are pickled and cold rolled, and are finished with a beautiful surface of an even color.

At a recent meeting of the stockholders of the Co-operative Stove Company of Blooomington, Ill., it was voted to increase the capital stock to $50,000. During the past year the company have enjoyed a good business and the stockholders are said to be well pleased with the condition of affairs as shown by the report presented. A new range has just been brought out, for which a popular demand is expected to develop.

The Joliet Stove Works of Joliet, Ill., have increased their capital stock to $100,000.

Combination Coal Range and Gas Stove.

A novel combination, by which gas burners may be used for cooking purposes in connection with an ordinary coal stove or range, has just been brought out by the Union Stove Works of 70 Beekman street, New York City. It is the invention of R. R. Finch, vice-president of the company, and Thomas H. Hodgkins, their pattern maker. It is designated as a combined cooking range and gas stove, and is so constructed that the gas burners may be used independently for ordinary cooking purposes, or they may be swung up under the high shelf of the range to keep dishes hot, while the top surface of the range is being used for the discharge of its usual functions. The illustrations which we present herewith convey a good idea of the manner in which the burners or gas stove, as it is called by the makers, are arranged. Fig. 1 represents a section through a burner as it appears resting on the top surface of the range, and also through the high shelf supported by brackets used in connection therewith. Fig. 2 shows the burners swung up immediately beneath the high shelf, and clearly indicates the manner in which they can be utilized for heating vessels placed thereon. The burners are two in number, and when in position on top of the range or stove are over the front boiler holes. They are firmly connected by an intermediate web of metal, while at the outer side of each of the burners is pivoted a link bar, having its opposite end pivoted to one of the side brackets of the stove, as shown in Fig. 1. In the front edge of each of the side brackets is a recess, while on each end of the gas stove or burners is a pin which enters the said recess, and in connection with the link bars holds the burners in place when they are swung up from the top of the range under the high shelf. In the latter are two pot holes or openings into which fit kettle rests that are upcast so as to project slightly above the top surface of the warming shelf. This keeps the vessels placed thereon far enough away from the top and the gas jets to allow of free combustion of the gas. When it is desired to use the combined functions of the range and gas stove, the latter, by means of its link connections with the side brackets,



Combination Coal Range and Gas Stove.—Fig. 1.—Sectional View, Showing Gas Burners Resting on Top of Range.

is raised so as to rest beneath the high shelf, with the gas burners beneath the pot holes into which are fitted the kettle rests referred to. The appearance of the device is then as represented in Fig. 2. When it is desired to use the gas stove alone it is swung down so as to rest on the boiler hole top of the range, with the parts appearing as in Fig. 1. When a large amount of cooking is to be done the combination arrangement can be employed,

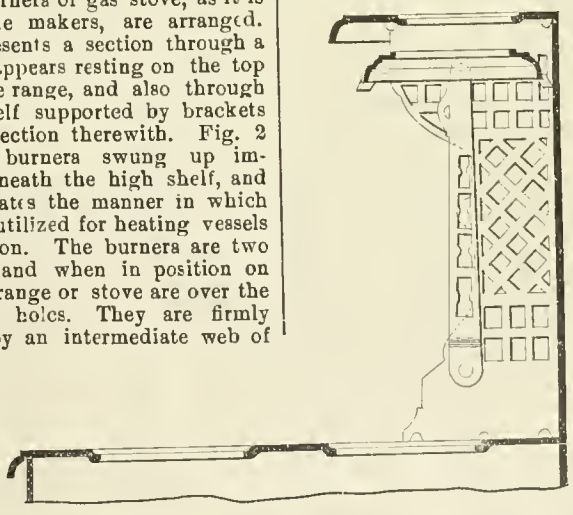


Fig. 2.—Appearance of Gas Burners when Swung Up Beneath the Pot Holes in High Shelf.

while in the summer months of the year it will be found convenient to use the gas burners independent of the range.

The Johnston Steamship Company of Liverpool have completed arrangements for the establishment of a line of whaleback steamers, to run between Baltimore and Tampico, Mexico, in connection with the Baltimore & Ohio Railroad. The service, which is to commence on April 18, will prove of great importance to Chicago, Pittsburgh, Cincinnati, Columbus, and the coal and coke regions of Pennsylvania, Maryland and West Virginia.

TRADE REPORT.

The Iron Market.

The market shows no decided change, and although the trade hope for the best there is but little chance of improvement until the tariff is settled. The bright springlike weather is having a good effect, and while nothing heavy is looked for, it is hoped that there will be at least the usual increase in the volume of business which is looked for during the spring and summer months.

Pig Iron.—Business in the New York market is light and no sales of consequence are reported. As showing how keen competition is, the fact is instanced that an order for 1000 tons No. 2, delivery Hoosick Falls, N. Y., was captured by a Virginia furnace. No contracts of any magnitude for Cast Iron Pipe have been placed lately. A very large order is, however, soon to come into the market. We quote standard brands $13 @ $13.50 for No. 1; $12 @ $12.50 for No. 2, at tidewater. Southern Iron, same delivery, $12.75 @ $13.25 for No. 1; $11.25 @ $11.75 for No. 2; $11 @ $11.25 for No. 3; $11.25 @ $11.75 for No. 2 Soft, and $11.75 @ $12 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10 50 @ $11.

Philadelphia advices intimate that sellers in that district claim to be finding a somewhat better demand, and notwithstanding the increased production, say they are placing all their output without making any sacrifice in prices. This may possibly be the case, temporarily; but so far as reports from consumers go, it is difficult to find anything to confirm the statement that business is actually larger than it has been at any time since the beginning of the year. Nevertheless, there is a general testimony from sellers that they can move more material at full prices and with less pressure. The trade feel very much encouraged, and it is hoped that before the end of the month the results will show that their ideas are well founded. Meanwhile sales are chiefly at figures quoted below for Philadelphia and near by points, but with a marked tendency to get away from the inside figures:

No. 1 Foundry	$13.00 @ $13.50
No. 2 Foundry	12.25 @ 12.75

Local Irons have been in moderate demand in the Chicago market, with no heavy transactions. Dealers state that under existing conditions it is perhaps better not to make long time contracts, because they simply lead to dissatisfaction as long as prices continue to decline. Sellers of Southern Irons generally report a very quiet trade; sales still confined to Soft Iron. Lake Superior Charcoal is moving in carload lots only. Prospects in a general way are looking up for an increased volume of business. The local foundries are doing more from week to week, although their orders are of a small character, seldom calling for more than a few columns and for small store fronts, &c. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @ $15.25
Local Coke Foundry, No. 1	12.00 @ 12.50
Local Coke Foundry, No. 2	11.50 @ 12.00
Local Coke Foundry, No. 3	11.00 @ 11.50
Local Scotch	13.00 @ 13.50
Ohio Strong Softeners No. 1	13.50 @ 14.50
Southern Silvery, No. 1	..... @ 12.50
Southern Silvery, No. 2	..... @ 11.75
Southern Coke, No. 2	11.25 @ 11.50
Southern Coke, No. 3	10.75 @ 11.00
Southern, No. 1, Soft	11.25 @ 11.50
Southern, No. 2, Soft	10.75 @ 11.00
Tennessee Charcoal, No. 1	15.50 @ 16.00
Tennessee Charcoal, No. 2	15 00 @ 15.25
Alabama Car Wheel	18.50 @ 18.65
Jackson County Silvery	15.00 @ 16.00
Other Ohio Silvery	13 00 @ 13.50

Makers of Pig Iron in the Pittsburgh district appear to have renewed confidence in the future of the market, judging by the way idle stacks have been going in during the present month. This means a very large increase in production, but it is believed that demand will soon show substantial increase. The product of Pig Iron in Allegheny County is now very close to capacity. Foundry Iron is moving only in small lots and prices are weak. We quote as follows:

No. 1 Foundry	$11.50 @ $11.75 cash
No. 2 Foundry	10.50 @ 10.75 "

In Southern markets there has been some increase in the demand for nearly all grades of Pig Iron during the week. Not that there were any round lots wanted, for either spot or forward delivery, but there was an increased number of small orders running from one to ten carloads, which in the aggregate make a larger volume of business than has been experienced for some weeks. The demand was largely for No. 3 Foundry and No. 2 Soft. No. 1 Foundry and No. 1 Soft was offered in excess of the demand, and some deliveries of No. 1 Soft were made on contracts for No. 2 Soft. There were sales of Charcoal Car Wheel Iron to a moderate extent and there are ample offerings at somewhat lower prices. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$11.00 @ $11.25
Southern Coke, No. 2	10.00 @ 10.25
Southern Coke, No. 3	9.50 @ 9.75
Ohio Soft Stone Coal, No. 1	14 50 @ 15.50
Ohio Soft Stone Coal, No. 2	14 25 @ 14 50
Lake Superior Coke, No. 1	13.00 @ 13.50
Lake Superior Coke, No. 2	12.00 @ 12.25
Hanging Rock Charcoal, No. 1	17.00 @ 17.50
Hanging Rock Charcoal, No. 2	16.50 @ 17.00
Tennessee Charcoal, No. 1	13.50 @ 14.00
Tennessee Charcoal, No. 2	12.50 @ 13.00
Standard Southern Car Wheel	16.75 @ 17.75
Lake Superior Car Wheel and Malleable	16.50 @ 17.00

Metal Market.

Pig Tin.—From the extremely low price touched last week there has been a reaction of nearly 1¢ per pound. During the period covered by the report in our last issue, as low as 18.25¢ was quoted. During the past few days bids of 19.15¢, net cash, for 5-ton lots, prompt or near future delivery, have been made and rumor has it that a few sales were quietly made at 19.20¢ @ 19 25¢. Despite this sharp movement in prices, speculation has not enlivened in the slightest degree; at least not on the Exchange. For that matter, the leading operators there have acted as though they were content with making official quotations and dealing out Tin in a jobbing way at corresponding prices. Purely speculative sentiment, however, would seem to have recovered from the shock given by tariff uncertainties and the depression in silver, but despite this circumstance and the advance that has taken place of about £3 per ton in London quotations the tendency to venture has been remarkably tame. This encourages the idea that the market is being manipulated, chiefly for the purpose of facilitating the distribution of Tin that has arrived since the duty of 4¢ per pound went into effect. How near the various theories may be to facts is problematical, but not a few distributors stated that their sales have increased to an encouraging extent since prices turned for the better. Consumers are said to be buying a little more freely, and inquiries have increased to some extent. Jobbers' prices for small lots are inclined to greater firmness at outside quotations.

Copper.—Purchases by home consumers have been on a somewhat more liberal scale; that is to say, the volume of business shows improvement as compared with the average of the preceding two or three weeks. No large individual transactions have taken place, however, and it is the general report that the deliveries called for have not exceeded 30 days. In fact, the bulk of the business has been for practically prompt delivery. Prices have undergone no radical change, but are still somewhat irregular. Lake Superior Ingot went at 9⅝¢ in lots of 25,000 to 50,000 lb, and any higher rate seems quite exceptional at the moment. Electrolytic is held at 9⅜¢, and casting brands at 9¼¢, but business has been effected very recently at concessions of ⅛¢ or more. The consumptive demand is said to be rather more active; that is to say, small orders are more frequently repeated

than has been the case for some weeks, and there is a moderate increase in inquiries. Jobbers' prices remain unchanged at former quotations for both Ingot and Manufactured Copper.

Pig Lead.—The market has developed a fairly strong tone and the improvement in that particular has been accompanied by a larger volume of business, with a little speculative interest besides. Of round lots there were sales aggregating 750 tons or more at 3.30¢ @ 3.35¢, and a number of single carload lots went at from 3.32½¢ up to 3.40¢ on the spot. The higher figures prevailed at the end of the week, with offerings moderate of stock for delivery before May, and spot supplies lighter than usual at this season of the year. In retail business no appreciable activity has yet developed. Purchases by consumers are still confined to absolute needs. Prices for small lots have not been advanced over last week's quotations despite the advance in wholesale price of the metal. The continued dullness in the building trades still serves to repress the demand for Manufactured Lead.

Spelter.—There has been hardly any business here except in single carload lots and not a great deal of that. The demand has continued very tame also, and, as far as New York is concerned, no improvement can be noted over the conditions that prevailed a week ago. Ordinary Western brands are still quoted at 3.85¢ @ 3.90¢ here, in carload lots, and the better sorts command little if anything more than the usual premium. Small lots from store command the usual premium of ½¢ @ ¾¢.

Tin Plates.—There has been little or no change for the better in the Tin Plate market during the week. Business in both spot goods and future deliveries continues disappointing and considerably below the average for the season of the year. Large consumers seem to be working on deliveries making on back orders, and they are contracting for future shipments in a very indifferent manner. Jobbers, too, are not inclined to anticipate future wants, and are limiting their orders for imported goods to the narrowest scale. The demand for spot goods from retailers and consumers shows but little improvement. In some quarters, however, a tendency is noted to the more frequent duplication of orders, and to this extent there has been improvement; although the individual orders are usually of small proportions. The whole trade is overshadowed by the tariff bill now under manipulation at Washington. No man will take more material than is absolutely necessary while the present condition of uncertainty continues. Consequently the jobbers look for little beyond a hand to mouth trade while this matter is in abeyance. Probably the most active business doing just now is in domestic Roofing Plates, for which there is a constant current demand. In the Western States the home product is said to be monopolizing the market, and the prediction is freely made that imported Ternes will not command a market in that section of the country in a few months. Prices are, if anything, slightly lower nearly all along the line, and concessions of 2¢ @ 5¢ ℔ box on desirable orders are not hard to secure.

Sheet Iron.—Black Sheets are in somewhat better demand, but the supply is ample and competition keen, resulting in the quoting of very low prices by manufacturers and dealers. Galvanized Iron is in much the same condition as Black. New concerns are making special inducements to secure trade, and are offering material at rates which must be very close to the cost of manufacture.

Chicago Report.

Scrap.—Business is extremely dull. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	...
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	...
No. 2, such as Shovels, Hoes, &c	3.00	...
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5 ¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5⅛¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—Trade is dull and prices are weak. Carload lots of 12 net tons or over are nominally quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.50

The National Tube Works, McKeesport, Pa., are reported to have booked more orders last week than in any other week in the history of the company.

CONDITION OF THE

Hardware Trade.

MARCH BUSINESS continues in fair, but moderate volume, trade being somewhat uneven in different parts of the country and for different lines of goods. In general terms business in the East and in the Southwest is probably better than in the West or Northwest, or on the Pacific Coast. The jobbing trade are not buying freely at the present time, having sufficient stock for their immediate requirements. Current orders are received principally from the smaller buyers who are getting their assortments in shape for spring business, a matter which many of them deferred until a later day than usual. It is also noticeable that orders are increasing in frequency and are for smaller quantities than the houses have been in the habit of buying. Manufacturers, also, are receiving a good many inquiries from parties who have heretofore bought chiefly from the jobbing trade, and there is a disposition in some staple lines to give the retail merchants relatively closer prices than has been the case. This comes from the solicitude of manufacturers to secure whatever orders are going. Advices from different parts of the country indicate that there is a tendency toward cutting of prices by the jobbers; and this fact, with the concessions which are being made by some manufacturers, tends to give some irregularity to current quotations. The tone of the market is thus not entirely satisfactory and far from strong. There are, however, comparatively few quotable changes. The trade at large are pursuing a very conservative course in the matter of purchases, and it will be the part of wisdom for manufacturers to refrain from forcing their goods on the market at unremunerative prices. With the opening of spring a quickening in the demand is anticipated, and there is at the present time a fair activity in seasonable goods. The financial conditions on the whole are quite satisfactory, and collections, though sluggish, give comparatively little reason for complaint.

Advices from Chicago.—Shelf Hardware maintains its appearance of activity and further gains are reported in the volume of business. Despite the improvement, however, it is not expected that the trade of this spring will rival the record of past seasons. The gap is too large to be overcome. Staple goods are quiet and straight Hardware is not moving sufficiently well to compensate for the lack of business during the early months of the year. Tinware and House Furnishing Goods are in considerably better demand, but the country merchants continue to buy broken packages which entail very much work in making up shipments. A somewhat improved demand is noted in Roofing Plates. American brands are taking the

lead in this direction, and the prediction is quite freely made that imported plates will not control any considerable part of this territory in three or four months. The heavy Hardware trade shows decided improvement. The demaud comes from all classes of manufacturing consumers, except the carriage builders, although some contracts are now being made for future delivery to a few establishments. Collections are improving.

Notes on Prices.

Wire Nails.—The Wire Nail market continues in the improved condition which has characterized it for the past few weeks. Prices are well maintained on a basis of $1.10 for carload lots, f.o.b. mill, and it is only in very exceptional cases where the orders are particularly large and attractive that this figure is shaded, and a slightly higher price is in many cases asked by some of the manufacturers. The mills are fully occupied with orders, and the current demand is sufficient to absorb their production, thus preventing an accumulation of stock.

Advices from Chicago.—The Local Wire Nail trade is affected to some extent by the reduced freight rates from Eastern factories. An equivalent concession is being made on factory lots, which brings the prices here to about $1.15. The price at factory is maintained, as the makers are still crowded with business and it will take some time for them to work off their orders. The demand continues fair from factory, but jobbers report some falling off in the demand from the retail trade. Small lots from stock are held at $1.25.

Cut Nails.—The demand for Cut Nails is fair, but not heavy, and the market is in substantially the same condition as last week, being characterized by not quite so strong a tone as for the past month or two. The following quotations are for carload lots delivered at the points named: New York, $1.05; Albany, $1.05; Buffalo, $1.02; Harrisburg, $1; Philadelphia, $1; Boston, $1.05, and Savannah, $1.05. It is understood, however, that slight concessions are in special cases made from these figures. The price from store in New York is $1.15.

Advices from Chicago.—Manufacturers of Cut Steel Nails report this month the best for a long time. Orders are larger and specifications are being freely made, so that shipments correspond well with order books. An encouraging feature of this trade is the continued demand from localities and dealers who have not for some time been taking Cut Nails, but whose trade has been given almost entirely to Wire Nails. One of the leading manufacturers now asserts that Cut Nails have seen their worst day. Prices are unchanged at $1.05, Chicago, for factory lots, 60 cents average. Small lots from stock are selling at $1.15.

Barb Wire.—Manufacturers of Barb Wire report an excellent demand, somewhat in excess of their expectations, and the mills generally are fully occupied on orders. The market is also in a very satisfactory condition as regards prices, which are steadily maintained on the following basis: Carload lots of Galvanized Four-Point, Pittsburgh, $2.15; Cleveland, $2 20; Cincinnati or Allentown, $2.25 ; Chicago or New York, $2.35, with an advance of 5 cents per 100 pounds in less than carload lots.

Advices from Chicago.—The Barb Wire trade steadily improves. Manufacturers are in receipt of continued orders from jobbers in various localities, and jobbers also report a fair demand from their customers. There is, however, less apprehension of an advance in prices, but values will probably remain at about their present level. Car load lots of Galvanized Barb Wire are selling at $2.30, and small lots from stock at $2.40.

Roller Staple.—The I X L Wire Fence Roller Staple, manufactured by O. P. Schriver & Co., Cincinnati, Ohio, is sold at $1.50 per hundred.

Glass.—The local Glass market shows no improvement either in demand or prices over that reported in our last week's issue. Reports from Pittsburgh indicate somewhat of an encouraged feeling among manufacturers, with slightly higher quotations for small quantities. It is not believed that the new tariff measure will become a law in time to affect the price of Glass made during the present blast, and this leads some to hope for an increase in price of Glass in the near future. It is understood that the Senate bill increases the duty on Glass about 12 per cent. above that proposed in the bill reported by the House. The American Window Glass market is represented in New York by quotations of 85 and 5 per cent. discount for single, and 85 and 10 per cent. discount for double. Pittsburgh quotations are reported as 85 and 10 and 5 per cent. discount for single and 85 and 20 per cent. for double strength Glass. An increase in capacity equivalent to 32 pots is noted during the past week. While no advance in the price of Plate Glass is reported, additional factories are making preparations to resume in the near future.

Old Metals.—Dealings in Old Metals are fair; but individual transactions are generally of but small proportions. Business is, in fact, still far below the average, and buyers evince only a languid interest in these materials. Scrap Iron has reached a point at which it is hardly worth handling, and lower prices than those now ruling seem to be out of the question. Dealers' purchasing prices for Old Metals, New York delivery, are about as follow:

Heavy Copper	℔ lb	7¢
Light and Tinned Copper	℔ lb	6¢
Heavy Brass	℔ lb	5¢
Light Brass	℔ lb	4¢
Lead	℔ lb	3¢
Tea Lead	℔ lb	2½¢
Zinc	℔ lb	2¼¢
No. 1 Pewter	℔ lb	13¢
No. 2 Pewter	℔ lb	6¢
Wrought Scrap Iron, ℔ gross ton	$7.00 @	$8.00
Heavy Cast Scrap, ℔ gross ton	7.00 @	8.00
Stove Plate Scrap, ℔ gross ton	4.00 @	5.00
Burnt Iron, ℔ gross ton	3.50 @	4.00

Old Rags, Paper, &c.—Business is merely of a commonplace character, and prices are practically unchanged. Improvement is, however, hoped for from day to day, meanwhile quotations are given as follows:

No. 1 White Rags	℔ lb	3¼ @ 3½¢
No. 2 White Rags	℔ lb	2¼ @ 2½¢
Mixed Rags	℔ lb	2¼¢
Blues and 3ds	℔ lb	1 @ 1¼¢
Hard Sized White Shavings	℔ lb	2¼ @ 2½¢
No. 1 White Book Shavings	℔ lb	2 @ 2⅛¢
No. 2 White Book Shavings	℔ lb	1 @ 1⅛¢
Light Book Shavings	℔ lb	¾¢
No. 1 Mixed Shavings	℔ lb	¾ @ 1 ¢
No. 2 Mixed Shavings	℔ lb	½ @ ¾¢
No. 1 Printed Books	℔ lb	1 @ 1¼¢
Ordinary Mixed Books	℔ lb	½ @ ¾¢
Newspapers	℔ lb	2-5 @ ½¢
No. 1 Manila Paper	℔ lb	1 @ 1⅛¢
No. 2 Manila Paper	℔ lb	⅞ @ ¾¢
Bogus Paper	℔ lb	½¢
Common Paper	℔ lb	⅝¢
Straw Chips	℔ lb	½¢
Binders' Clippings	℔ lb	½ @ ⅝¢
Jute Butts	℔ lb	1⅞ @ 2 ¢
No. 1 Jute Bagging	℔ lb	1 @ 1¼¢
Mixed Bagging	℔ lb	¾ @ 1 ¢
No. 2 Bagging	℔ lb	½ @ ⅝¢
Hemp Twine	℔ lb	2 @ 2¼¢
Manila Rope	℔ lb	2¼ @ 2⅝¢
Jute Rope	℔ lb	1½ @ 1¾¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Old Rubber.—There is very little doing in Old Rubber, and prices remain at the low level they have held for some time past. The following quotations represent about the rates paid in New York.

Car Springs, ton lots, ℔ lb.	.... @	$0.03¼
Rubber Shoes, carloads, delivered at factory, ℔ lb.	.... @	.03
Rubber shoes, less than carloads, ℔ lb.	0.02¼ @	.03⅛
Large Hose, ℔ ton	.... @	9.00
White Wringer Rolls, ℔ lb.	.... @	.04¼
White Syringes, ℔ lb.	.... @	.05

Trade Notes.

The Oil Well Supply Company of Pittsburgh, Pa., and 32 Cortlandt street, New York, are just issuing a new catalogue of 375 pages in a brown cloth cover. The first 30 pages are devoted to engravings of their different manufacturing plants and to showing some of the apparatus in use. The balance of the book is devoted to derricks for drilling and driving pipes and the different machinery connected with oil wells and a number of gas fittings and cocks. Several pages are given to a varied line of gas burners for natural gas adapted for use in cooking and heating stoves.

Merry & Clark, 535-547 West Fifteenth street, New York, have in stock and are receiving daily a large supply of Merry's Old Method Stamped Roofing Plates, which are meeting with an excellent demand. Merry's Lion American Terne and imported Monarch Old Style Ternes are also popular Plates and are selling freely. The notice in our advertising columns gives the particulars of their agency for Clark, Quien & Morse, Peoria, Ill., makers of Conductors, Eave Troughs, Gutters, Elbows, &c.

I. W. NUMAN, Canton, Ohio, distributes circulars illustrating and describing a variety of Pumps that he manufactures. These include Lawn Pumps, Sprayers and Fire Extinguishers. The advantages of the different devices are referred to in the circular.

C. R. DUNDORE has withdrawn from the firm of A. P. Swoyer & Co., dealers in Brass and Copper, 17 North Seventh street, Philadelphia. The business is continued by the other partners, A. P. Swoyer and J. W. Gaskill, under the old firm name.

HOWE SCALE COMPANY, Rutland, Vt., have arranged to make a complete line of Belknap Motor Company's Cyclone Coffee Mills which will be put on the market as the Howe Cyclone Mills. This concern has recently completed a plant for icing refrigerator cars for the Armour Fresh Beef Company, Kansas City, and are building an unloading plant for the Shore Sand Company, Millwaukee, Wis., which will take sand or coal from boats and deliver to the yards at the rate of from 60 to 90 cubic yards per hour. This plant consists of a trestle 18 to 20 feet wide, 20 to 22 feet high, extending the entire length of wharf.

THE OMAHA TINWARE MFG. COMPANY, Omaha, Neb., have been reorganized under the name of the Standard Tinware Mfg. Company.

ARTICLES OF INCORPORATION were recently filed by the Michigan Brass & Iron Works, Detroit, Mich.

A. ST. J. NEWBERRY, assignee of the Lorain Mfg. Company, issues a notice from Cleveland, Ohio, under date of March 9, to the effect that the report that the Lorain Mfg. Company had been reorganized, officers elected and arrangements made to start the works was entirely premature. The plan is under consideration, but it has not yet been finally agreed upon. The notice adds that the creditors will be advised as soon as definite statements can be made.

THE WHITAKER IRON COMPANY, Wheeling, W. Va., manufacturers of Black and Galvanized Sheet Iron, have placed a contract for the erection of their new steel rolling mill building, to replace the one destroyed by fire on November 12 of last year, with the Shiffler Bridge Company of Pittsburgh. The contract calls for the completion of this building within 90 days from February 28, but it is somewhat doubtful whether the plant will be ready for operation before summer. This building will be of steel, its dimensions being 135 x 515 feet. The statement that the contract price was about $100,000 is untrue, the cost being very considerably less than this amount.

THE LAMP DEPARTMENT of Holmes, Booth & Haydens, Waterbury, Conn., is now running eight hours a day, five days a week. Until recently it has run only four days. In the main mill the employees are working six days, eight hours a day.

THE FERRACUTE MACHINE COMPANY of Bridgeton, N. J., manufacturers of Presses and Dies, report that there are many more inquiries recently, and that their orders have gradually increased during the month of February, more orders having been received last week than in any previous week since last May. They have during the past year kept their pattern makers and designers at work, and have ready for the market a large number of new designs for Presses and other sheet metal machinery. All of their older Presses have been redesigned.

AVERY STAMPING COMPANY, Cleveland, Ohio, announce that their works are now in full operation. They state that they are prepared to name prices upon Steel Hollow Ware, Pressed Steel Seats, Washers and all kinds of light and heavy metal stamping and shearing of Steel Plates to pattern, such as Circles, &c.

SCOVILL MFG. COMPANY, 423 Broome street, New York, who for some time have been manufacturing a large line of Aluminum Novelties, Art Goods, &c., have perfected a number of additions to the assortment, among which may be mentioned Hair Brushes, Soap Boxes, Framed Mirrors, Shaving Mugs and Brushes, Perfume Bottles and Atomizers, Salt and Pepper Boxes, Drinking Cups and Mugs, Lemonade Shakers and Soda Glass Holders, Hair Pins, as well as some new patterns of Cabinet Picture Frames.

PEERLESS FREEZER COMPANY, Cincinnati, Ohio, advise us that this year they are making a 2-quart Peerless Freezer in addition to those mentioned in our issue of March 1, 1894. Their line of Freezers includes the Peerless, Giant and Zero, in sizes from 2-quart to 10-gallon.

The steady growth of the anthracite coal tonnage of Pennsylvania is shown by the *Coal Trade Journal* for the past seven years as follows:

1887	34,641,017	1891	40,448,336
1888	38,145,718	1892	41,893,320
1889	35,407,710	1893	43,089,536
1890	35,865,174		

The same authority places the total production of coal in the United States during the last year at 166,133,062 tons, a gain of more than 12,000,000 tons over the previous year. Of this amount only about 3,600,000 tons was exported, mainly to Canada and Mexico.

The Michigan Labor Bureau has made a thorough canvass of the present condition of labor in that State as compared with one year ago. During the period between September 1 and February 1, a total of 2066 factories and mills in all parts of the State were inspected. Of these, 377, comprising some of the most important, were entirely idle. Of those reported in operation, 1117 were running full time and 572 on short time, the latter showing a loss to labor of 82,627 hours per week. The number of workers laid off is 48,725, or about 43 per cent. of the whole. There has been an average reduction of wages in factories visited of 9.5 per cent.

The House Committee on Judiciary have reported favorably on a bill introduced by Representative Turner of Georgia providing that a receiver or manager of any property, appointed by any court of the United States, may be sued in respect of any transaction of his in carrying on the business, without previous leave of the court, exactly in the same manner as process would be served on the corporation if it were not in the hands of a receiver.

February's fire loss in the United States keeps up the large average of recent months, being $11,300,000, as compared with $10,000,000 for February, 1893. These continued heavy fire losses are beginning to bear hardly on the insurance companies. The *Journal of Commerce* says that 1894 threatens to be remarkable for its fire insurance failures.

That the Hardware firm of Coon & Ellingson, Edgerton, Wis., have been dissolved by mutual consent. Mr Ellingson will continue the business.

Price-Lists, Circulars, &c.

ACME BELL & DEVICE COMPANY, 11 Gold street, New York, and Lancaster, Pa.: Bells, &c. An illustrated price-list shows the Acme Door Bell, Challenge Door Bell, Hotel Call Bells, Family Call Bells, Bicycle Bells, Bicycle Locks, &c.

THE SANDWICH ENTERPRISE COMPANY, Sandwich, Ill.: Descriptive circular of an Aërating Pump. This Pump is so constructed that the valves can be reversed, when the Pump forces air downward instead of lifting water up. In this way cisterns are aërated much more rapidly and effectively than when pressure is not applied to the downward current of air. The valves are reversed by a small lever at the front side of the base. This Pump was exhibited in operation at the World's Fair, and many orders were there taken from persons who have since sent in testimonials of excellent results obtained.

CAVERHILL, LEARMONT & Co., Montreal: Price current of seasonable goods. The book is devoted to illustrations and descriptions of Screen Doors, Window Screens, Wire Cloth, Screen Door Hinges and Catches and Lawn Mowers. The goods shown are largely of American manufacture.

By a thoroughly reliable man, expert in pump, wind mill and water supply business; well up in all kinds of machinery; have ability to manage factory or branch house. "Reliable," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 17

By a TINSMITH. Alex. Lottis, 112 Madison street, New York City. Mar. 17

As STOVE MOUNTER; 14 years' experience; have worked at all kinds of Work Chas. Diemer, 2209 East Thompson street, Philadelphia, Pa. Mar. 17

By a young man, as PLUMBER; some knowledge of tin work; steady, sober; city or country. "Plumber," 160 Walnut street, Bloomfield, N. J. Mar. 17

By a cornice and skylight maker, as FOREMAN of a small cornice shop, or assistant cutter in a large shop; nine years' experience; 27 years of age; understands English and German. L. D. Retman, 111 Delancey street, New York City. Mar. 17

As CORNICE MAKER and CUTTER, middle aged man, German; first-class hand on steam curving, mold machine or hand work. "A. C," care of G. Waker, 223 East Eighty-ninth street, New York City. Mar. 17

By a first-class DESIGNER and MODELER; long experienced; able to do lead in fancy trimmings and general ornamentations; original and fast. "Designer," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 17

By a MECHANICAL DRAFTSMAN who thoroughly understands heating and ventilating in all its branches; strictly temperate and reliable. J. P. Lisk, 636 Monroe street, Brooklyn, N. Y. Mar. 17

By a first-class CORNICE CUTTER and FOUNDER; 12 years' experience; not afraid of work; references. "F. F.," care of Broadbeck, 568 Ninth avenue, New York City. Mar. 17

As FOREMAN for a tin, sheet iron and cornice shop; 18 years' experience; or would like to hear of some good town to start business in. "J. B. B.," 12 Indiana place, Boston, Mass. Mar. 17

By a PRACTICAL COPPERSMITH, 20 years' experience; city or country. H. Schneiderman, 88 Essex street, New York City. Mar. 17

By a young PRACTICAL LEAD BURNER, with a good knowledge of plumbing, with some good plumber who could employ him to advantage; wages reasonable; references furnished. "W. H. S.," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 17

By a young man, as a PLUMBER'S ASSISTANT; some experience at tinoing; Newark preferred. Wm. Bolz, 412 Washington street, Newark, N. J. Mar. 17

By a TINNER; understands all kinds of job work and plumbing; sober and industrious; married. C. F. Richards, Box 752, Gouverneur, N. Y. Mar. 17

By a PLUMBER; city or country. Arthur Wickers, 1406 Third avenue, New York City. Mar. 17

By a PLUMBER; city or country Wm. Clark 418 East Sixteenth street, New York City. Mar. 17

Steady work desired by a first-class SLATE ROOFER; some knowledge of tin work. Wm. P. Kennedy, General Delivery, St. Louis, Mo. Mar. 17

BOOKKEEPER and SALESMAN; young man, 24, a practical and thorough accountant and experienced in the hardware and stove trade; A1 references as to character and ability. "C. F. P.," 142 North Twentieth street, Philadelphia, Pa. Mar. 17

By an experienced TINSMITH, willing to work; city or country. Max Cohn, 148 Delancey street, New York City. Mar. 17

By a first-class PLUMBER, STEAM, HOT WATER and GAS FITTER; some knowledge of tin and sheet iron work; married; sober; good references; steady position desired. Edw. E. Silvey, 163 Locust street, Dover, N. H. Mar. 17

By a first-class PLUMBER, GAS, STEAM and HOT WATER FITTER; 14 years' experience; have worked in some of the best shops in New York City; references if required. Wm. Ashworth, Haledon P. O., N. J. Mar. 17

As BOOKKEEPER and CORRESPONDENT; understands the oil stove business thoroughly; well acquainted with the New England trade in that line; large experience; competent to take charge of an office; A 1 references. "B. and C.," office of *The Metal Worker*, 96-102 Reade street, New York City. Mar. 17

By a TINSMITH; five years' experience; also understands plumbing; New York State preferred. Robt. C. Clifford, Potsdam, N. Y. Mar. 17

Steady work, by a young man used to all kinds of tin, sheet iron and furnace work; some knowledge of lead and iron pipe work; sober and good workman. L. H. Atkinson, Virginia P. O., Ontario, Canada. Mar. 17

BRASS WORKER wants a situation as bench hand, soldering, brazing or any other work. "Brass Worker," office of *The Metal Worker*, 59 Dearborn street, near Randolph, Chicago. Mar. 17

By a young man, 28 years of age, with 13 years' experience at tin and sheet iron work, roofing, cornice, stove, range, heater and furnace work; understands English and German. John Finck, 604 East Ninth street, New York City. Mar. 17

Unmeaning Trade Terms.

There will be found in another department of this paper a letter from H. M. Sanders of Washington, under the title of "Cutter," in which he discusses a question that must often have arisen in the minds of those concerned with sheet metal work. Every one will agree with the reasonableness of his argument, which is that the term "cutter" is used in an entirely incorrect way. In the present day pattern cutting really means pattern drawing, and the work of actual cutting is in no way whatever related to the work of laying out a pattern. Our correspondent, however, is, we think, unduly exercised about this misnomer, or, rather, there are so many other absurdities in trade speech that if he undertook the task of reforming trade language he would have a labor that would occupy him through a Methuselah's lifetime. Especially about sheet metal do the absurdities seem to cluster. Any one at all familiar with tin plate nomenclature must call to mind a variety of descriptive terms whose original meaning has entirely disappeared. The coke and charcoal designations which formerly had a proper significance are now merely equivalent to any other adjectives expressing two grades of excellence.

Slow Reformation.

Reformation is coming about by very small degrees, but it is coming about nevertheless, and will ultimately prevail even, we believe, in that fortress of conservatism, the tin plate trade. The beginning of American manufacture has let in the entering wedge, and it is likely before many years that tin plates, both in their dimensions and qualities, will be classified in a more simple manner. We would not criticise exclusively the tin plate trade, for others are similarly open to attack. There is galvanized iron for instance, originally iron electroplated with zinc, which now, however, is made without any assistance from the galvanic current. The name has stuck after its significance has entirely disappeared. Or even the word "iron" itself in this connection might be cited as an example, since it is a well known fact that the material for practically all of the sheets is steel. Instances of a similar kind could be multiplied as long as space held out, but the few given are sufficient to indicate the work that is before whoever purposes to reform sheet metal nomenclature.

The Boland Trade Schools.

The handsome building on Madison avenue, between Fifty-first and Fifty-second streets, New York; known as the Boland Trade Schools, is now complete, and was opened with great ceremony by the Roman Catholic Archbishop in January last. The school, which has been erected for the benefit of the older boys of the Roman Catholic Orphan Asylum, is as yet only in operation so far as the theoretical classes are concerned. Practical trade instruction has not been begun, owing, it is understood, to lack of funds. The workshops occupy the whole of the ground floor of the building, and are spacious, light and well ventilated. The plumbing class room is, so far, the only one that has been equipped for work. It is possible that this department will start into operation in the course of a month or six weeks.

The World's Fair Buildings.

The South Park Commissioners, who now own the Chicago World's Fair buildings, were evidently greatly surprised at the bids they received for those structures on the 10th inst. From common report, contractors generally were expected to demand a bonus for the removal of the buildings, on the ground that it would cost more to remove them than the material could be sold for. But when the bids were opened, it was found that the buildings were considered of some value. Taking the highest bids on all the buildings, the commissioners would have received $36,596. This threw a new light on the subject. It was at once believed that if the buildings were worth so much they were worth a great deal more, and the bids were, therefore, incontinently rejected. Efforts will now be made to sell the several structures at private sale, in the hope to realize more. This is a case in which bidders injured their chances by bidding too high. They should have asked a bonus for removing each building. The Park Commissioners, it will be remembered, have been paid $200,000 by the World's Fair Commissioners to take the buildings off their hands, and the latter thought they had made a good bargain by getting out of the cost of removing the buildings, which they feared might exceed that amount.

The Tariff Bill.

Exasperation is steadily increasing among business men at the endless delays which are keeping the community in suspense concerning the future of the tariff. Week after week is spent in backing and filling, and predictions are growing more positive that the decision will not be reached until the summer heat drives our legislators from Washington. The fact seems to be forgotten by Congressmen that the interests in political questions which are paramount with them play a very subordinate role with the great mass of the people. With them lucrative employment of their labor or their capital is the consideration before which all others fade into insignificance. Americans are a long suffering people, but they will not indefinitely allow talkers to paralyze the men of action. To the workman who is out of employment or who is struggling along at cut wages and to the business man who is feeling himself drift hopelessly toward insolvency, high political interests have no meaning. They want immediate relief.

The regular monthly meeting of the Association of Iron and Steel Sheet Manufacturers was held in the *Times* Building, Pittsburgh, last week. Only routine business was transacted. The condition of the sheet trade at this time was reported to be very much depressed. None of the mills are working full time, while prices are very much lower than ever before in the history of the trade.

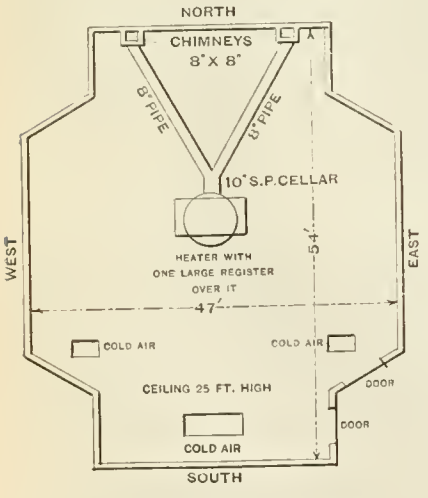
The British naval estimates for the year 1894–95, which were issued last week, show that the Government proposes to spend $83,355,000 on the navy in the next financial year. This is $15,000,000 more than the amount used in the past year; and it is described as being but a part of a complete programme which is to cover the operations of the British Admiralty for the next five years, the money for which will be voted in five annual installments. During the coming year seven new battle ships of the first class will be built, as well as six second class cruisers, two sloops and 36 torpedo destroyers of a new design. The *personnel* of the service is to be increased by 6700 men.

Liverpool's electric elevated railway, which has been in operation for a year, has proved entirely successful. A five-minute service of trains is maintained, and no mishaps of any kind have occurred. The road is 5 miles long, and cost, including equipment, $2,650,000.

THE LETTER BOX.

Wants Furnace Suggestions.

From A TINNER, *Montana.*—As a reader of *The Metal Worker*, I would like to ask a few questions on heating the church shown in the sketch. At each of the corners are halls and anterooms, but I do not include them in the plan, as they are not heated. The ceiling is not all of one hight, being 26 feet high in the center and 15 feet high at the sides, making a space of about 50,000 cubic feet to be heated by a furnace setting 18 feet from the chimney, which has a capacity to heat 70,000 cubic feet of space. It is connected with but one chimney now, which does not seem to have sufficient draft. Would it be better to connect it with both, as shown? There is one 27 x 38 inch register directly over the furnace, and cold air is supplied through ducts connecting with a 21 x 29 inch register at the front and two 13 x 21 inch registers, one at each side in the floor. The church is somewhat exposed to the winds by having a street on the east and south sides. It is moderately well built, and our coldest weather has been 16° below zero, which is a very rare occurrence. It is proposed to make some changes during the coming season, and I therefore ask



Wants Furnace Suggestions.

my fellow readers and *The Metal Worker* to make such suggestions as they think would aid in heating the church better than it is now heated. Would four smaller registers give better results? The furnace has a 10-inch smoke collar. Would it do better work if a Y was used to connect it to both chimneys, using an 8-inch pipe, or would it be better to build a round elbow in the bottom of the chimney and taper it to 10 inches in diameter and run a 10-inch pipe all the way from the furnace? Would two furnaces set to the right and left of the present heater with equal capacity to it heat better? They could not be set further to the front of the church conveniently. Is the hot air register large enough? Is there any rule for estimating or proportioning the capacity of the register to the furnace by which the proper size can be known? There is no ventilation in the church except by opening windows. The chimneys are straight from top to bottom and are well above surrounding buildings.

Note.—This call for assistance can best be satisfied by some of our experienced readers, and we hope they will respond freely. It is probable that more satisfactory criticism and suggestion could be made if the hight of the furnace cellar and the material, shape and dimensions of the cold air ducts were given. The chimney seems to be a troublesome feature in this case, and from the opinions expressed in *The Metal Worker* last December on connecting a boiler with two chimneys, the suggestion of building an elbow in the chimney and running the large pipe to it would seem the best. When a good draft is established and the furnace is under the full effect of a bright fire, it should do much better work, and improving the draft may prove a sufficient remedy. From the size of the smoke outlet in the furnace it would be naturally inferred that soft coal is burned, and to many the chimney would seem to lack capacity for the work even with the larger pipe. A rule used by a correspondent for computing furnace capacity was given in *The Metal Worker* January 20, which may be of some assistance. The register used seems amply large and the cold air registers are larger in proportion than are generally used, but the size of the ducts would have an important bearing on their efficiency.

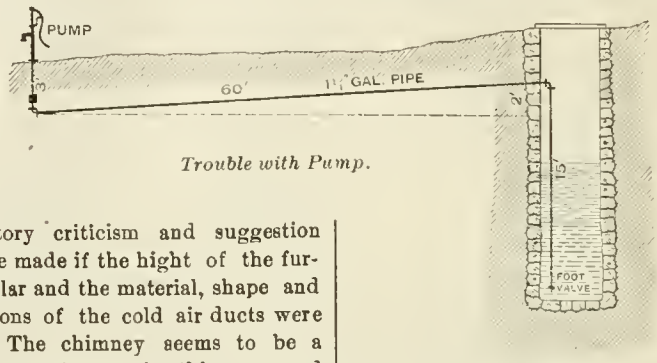
Pattern of Flaring Article—Oblong Bottom and Round Top.

From J. W. C., *Fillmore, N. Y.*—Please publish in *The Metal Worker* a method for obtaining the pattern of a flaring joint of pipe used on a sugar arch. The base of pipe to be oblong with semicircular ends, 10 x 32 inches, and the top to be round, 15 inches in diameter.

Note.—A method for obtaining the pattern of an article similar to the one desired by our correspondent was published in *The Metal Worker* of December 9, 1893.

Trouble With Pump.

From F. B. K., *Delaware, Ohio.*—I put in a pump as shown in the illustration and it does not work right. Perhaps some of the readers of *The Metal Worker* can tell me where the trouble is located. I put in another pump the same way, except that it was lower at the well than at the pump, and it worked without trouble. I think, therefore, the fall in the pipe may be the source of the difficulty in the present case and I would like the opinions of some of the readers on the subject.



Trouble with Pump.

Difficulty With Drive Well.

From E. B. S., *Mount Vernon, Ind.*—After reading the article of "W. M." of Little Falls, N. J., February 17, I infer that he attached a new pump to an old drive well. The presumption is that the old pump was worn out and a new one was put in its place. If such is the case, he will save time and money by drawing the pipe and putting on a new point with strainer fine enough to exclude the kind of sand in which the point gets its supply of water.

Roofing Queries.

From O. J. B., *Troy, Ind.*—In reply to "J. H. W.," in *The Metal Worker*, February 10, I employ the same method in putting tin together that he uses, but do not solder cross locks for standing seam roofing when the pitch is over 1 inch to the foot, and my roofs have always given satisfaction. In laying flat seam roofing a pair of ½-inch tongs is used to turn the edges on the strips. I never put a flat seam roof on in strips, if the strips run over 10 or 12 feet in length, but put it on one sheet at a time. I never nail my sheets or strips down by driving nails through them, but use cleats and nail them as close to the edge as possible and then mallet the seam down and use rosin for a flux in soldering. The rosin is applied by using an old soldering copper, heated hot enough to melt the rosin. The point of the soldering copper is placed on the seam and a lump of rosin is held on the heated copper which melts and runs down as the copper is drawn along the seam. In regard to painting roofing on both sides before it is put on, the idea is

good, but it interferes with the workmen if any soldering is to be done. I never let a roof remain unpainted any longer than a week if the weather permits me to paint it.

Tinner and Plumbers' License.

From R. Z., *Hoboken, N. J.*—Kindly inform me in *The Metal Worker* if it is necessary for a tinsmith to have a license to do plumbing and repairing inside of houses.

Answer.—In a great many cities plumbing work is subject to regulations made by the Board of Health, and in some places a plumber is required to take out a license. This is to provide that work that is important from a sanitary standpoint shall be done by competent men. Any man who is competent to do work can secure a license, and if it is required by the authorities no attempt should be made to work without one.

Objects to Exposed Piping.

From D. B. T., *Northville, N. Y.*—Replying to the inquiry of "L. W. F." in *The Metal Worker* March 10, I have a boiler from which the pipes go down to the cellar, then up through a partition to a bathroom. It has been in use two years, working all right, never making any trouble. The faucets for the sink are connected in the partition.

Who Makes It?

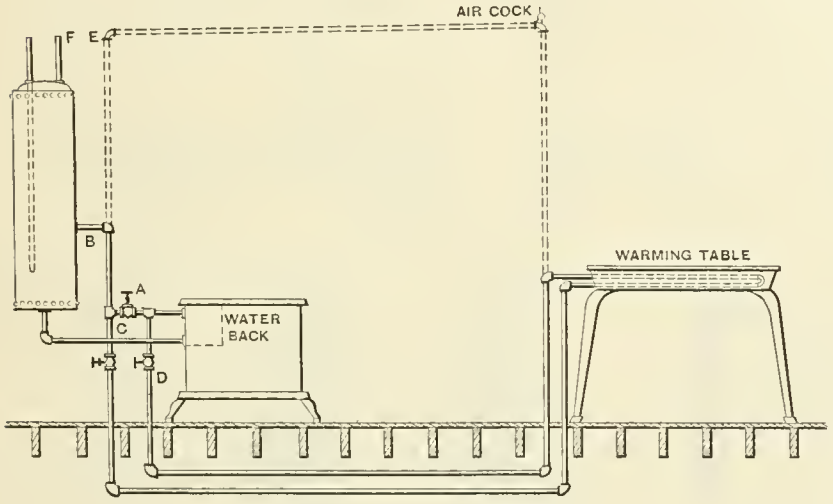
From C. F. C., *New York.*—Can some reader of *The Metal Worker* tell me who makes the Hyde Park hot water boiler?

Choked Flues.

From THOMAS HYDE, *Albany, N. Y.*—To enter into a theoretical explanation of the cause of the draft in the chimney of which "V. T." complains in *The Metal Worker*, March 10, would be too lengthy for me to take up at present. However, I will recommend that he takes a 7 or 8 inch pipe directly from the boiler to the chimney and up inside of it to a point a foot or more, as he chooses, above the top of the brick chimney, and stop up the opening at the point of entrance to the chimney, and also on the outside of the pipe at the top of the chimney. Then if the chimney is located as he says, so that the draft is not impaired by higher buildings nearby, and he does not find the draft increased 100 per cent., in fact, all that he can possibly need, I will agree to pay the cost of the experiment. A round flue is by all means the best. A properly proportioned square flue will work well enough.

Range Boiler and Warming Table.

From G. F. W., *Windsor, Conn.*—Please inform me in *The Metal Worker* if I will be able to get a circulation of hot water through the loop in the warming table without the aid of the stop at A in the illustration. I want to put in the warming table so I can shut it off from the range boiler when not in use and still use the range. Will the system work as I have it arranged, and will it give heat enough to keep dishes and food warm? The loop lies in a copper pan to be filled with water if necessary, and the table has covers to prevent loss of heat.



Range Boiler and Warming Table.

Answer.—In the system shown under heavy firing steam would form in the water back when the boiler was shut off, and the circulation that could be secured would not produce satisfactory results. To obtain proper circulation we would suggest piping it in the following manner: Use a T at the side connection of the boiler, with a stop cock between the T and the boiler at B. Run the pipe from the top of the T up to the ceiling and across to the warming table, as shown by the dotted lines, putting in an air cock, and then drop down and conect with the loop. Bring the return from the loop down and under the floor, as shown, and up and connect with the lower pipe from the water back at C, with a stop cock just below the connection, and take out the stop cock at A and all of the piping with the stop cock D on it between the warming table and where it connects with the water back pipe. This system of piping will permit a free circulation, and if any steam is made it can leave the water back. When hot water is to be used to heat the warming table the stop cock at C should always be opened first, then by closing the stop cock at B the hot water from the water back cannot enter the boiler, but must circulate through the coil. This system of piping will shut off the boiler, which may be objectionable, and if the water back has the capacity to heat water for both the boiler and warming table a connection from F to E will make the stop cock at B and the piping from the T at B up to E unnecessary. With this method of piping circulation through the table can always be cut off when desired by closing the stop cock at E. The amount of heat secured at the warming table will depend on the amount of surface exposed in the coil. If the coil is in water, it should have 1 square foot of surface for every 3 or 4 gallons of water, according to the temperature of the water in the coil and the amount of heat wanted at the warming table, and as it is improbable that the copper pan will hold more than half as much water as the boiler there should be no difficulty in securing satisfactory results if the coil is properly proportioned to the work.

Furnace Gas Burners.

From H. J. DAVIS, *Friendship, N. Y.*—I notice an inquiry in *The Metal Worker* of March 17 from "I. W.," asking for information in regard to apparatus for burning gas in a hot air furnace. Being a practical gas fitter, I submit the following for the benefit of "I. W.": If the gas main to which he intends to connect his furnace has a light or low pressure, he should put in a burner large enough to throw the blaze against the fire pot and sides of heater, in order to get good results. A considerable quantity of ordinary brick placed around the burner will help to hold the heat.

From MCCAHAN & CO., *Baltimore, Md.*—In answer to "I. W." in *The Metal Worker*, March 17, would say that we have a burner suitable for either furnace or cook stoves that is powerful and economical and requires but little space.

From SWIPED JOINT, *Charleston, W. Va.*—If "I. W.," who made inquiry about gas burners in *The Metal Worker*, will get the rules for setting the Economy furnace burner, made by J. E. McNamara, Columbus, Ohio, he will be able to decide as to its adaptability for his purpose.

Repairing Enameled Ware.

From J. L. S., *Baltimore, Md.*—Please tell me the best way to put tin or copper bottoms on enameled ware.

Note.—If our correspondent will consult *The Metal Worker* of October 7, 1893, he will find a letter with illustrations describing the work that he asks about.

Lake navigation for the 1894 season opens six weeks earlier than has been the case for years. Advices from Cleveland, Ohio, state that most of the fleet of boats have been fitted out. More than a dozen of the heaviest lake carriers left Cleveland port at the close of last week.

ROOFING AND CORNICE.

The Country Cornice Shop.

VIII.

BY CORNICE WORKER.

Leader Pipes.

Let Fig. 61 represent a section or profile of a round leader, the seam being shown at A. Fig. 62 is a rectangular or, as it is commonly called, a square leader, the seam being shown at B. The seam in Fig. 62 is supposed to lay against the wall of the building, but it is better to place it as shown at B′, so that in case the leader bursts the seam can be readily repaired without removing the leader. Fig. 64 represents a section of an octagon leader, the seam being shown, as indicated at E in Fig. 63. To draw the shape of the octagon leader, shown in Fig. 64, to full size, proceed as follows: Draw a square figure to the required size, as shown by A B C D, Fig. 63, and let F indicate the width of the corner which is to be broken. With C as center and F as radius, strike an arc, cutting the lines B C and C D; then again, with the same radius, and with D A and B as centers, strike the three arcs as shown. Draw lines through the intersections made upon the square, which will give the section of the octagon leader required, as shown in Fig. 64. Fig. 65 represents a section of a corrugated leader, which can only be made by those having special machinery for that purpose, but can be obtained in 8-foot lengths from dealers in tinners' supplies.

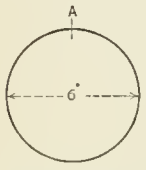


Fig. 61.—Section of Round Leader.

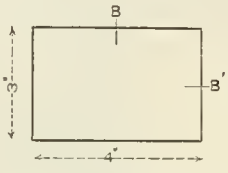

Fig. 62.—Section of Square Leader.

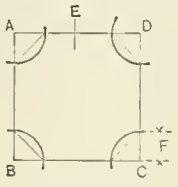

Fig. 63.—Obtaining Broken Corner for Octagon Leader.

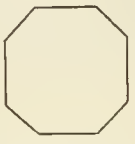

Fig. 64.—Section of Octagon Leader.

Fig. 65.—Section of Corrugated Leader.

Fig. 66.—Round Leader Riveted and Crimped.

Fig. 67.—Notching Flange on Square Pipe.

Fig. 68.—Square Riveted Leader with Flange Completed.

Fig. 69.—Octagon Leader Riveted.

Fig. 70.—Corrugated Leader.

Fig. 72.—Strip for Marking Rivet Holes.

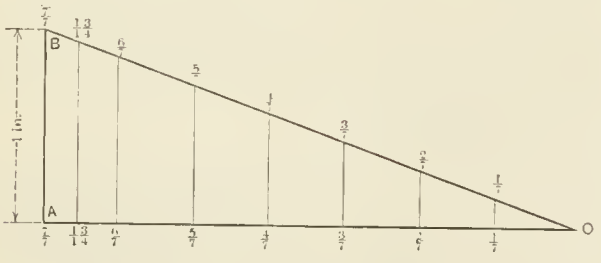

Fig. 71.—Diagram for Obtaining Fractional Parts of an Inch.

Fig. 73.—Rivet Punch.

THE COUNTRY CORNICE SHOP.

Fig. 66 is a perspective view of a round leader riveted and crimped at A. If the tinner has no crimping machine it is advisable to obtain one, as a great amount of time and labor is saved over the old method of drawing in the pipe on the mandrel stake. Fig. 67 is a perspective view of a square or rectangular leader, and shows the method of notching the flange joining into the next joint of pipe. Let us suppose that a 1 inch flange is required; then placing the width of the dividers to 1 inch, scribe a line round the top edge of the joint of leader, as shown by A B C D, Fig. 67, and measuring with the eye about ½ inch from the corner, cut a notch on each corner with the snips, as shown by the four dots over the lines A, B, C and D. It will be noticed that the flange is notched once on each side of the leader and the flanges bent slightly toward the inside of the leader, thus giving the appearance as shown in Fig. 68. Fig. 69 is an octagon leader, the flange for joining being notched in the same manner as described in Fig. 67, the only difference being that the square leader is notched on four sides, where the octagon leader would be notched on eight sides. Fig. 70 is a perspective view of a corrugated leader, the flange A being drawn in in manufacture.

Obtaining the Circumference.

Fig. 71 shows the method of drawing a full size diagram for obtaining

any fractional part of an inch, which is to be used when obtaining the circumference of any size of round pipe. Let us suppose that the diameter of the pipe shown in Fig. 61 is 6 inches; the rule for obtaining the circumference of any size round pipe is to multiply the diameter by 3.1416, which is a little more than $3\frac{1}{7}$: therefore the rule used in practice is to multiply the diameter by $3\frac{1}{7}$. To obtain the circumference of a pipe 6 inches in diameter, multiply 6 inches by $3\frac{1}{7}$, which equals $18\frac{6}{7}$ inches without lap ($\frac{3}{4}$-inch lap is usually given). To obtain the $\frac{6}{7}$ inch, construct the diagram as above referred to as follows: Draw any line, as A O, Fig. 71, to any

quired which was $4\frac{3}{4}$ inches in diameter, the same rule would be employed. Multiplying $4\frac{3}{4}$ inches by $3\frac{1}{7}$, the result would be $14\frac{13}{14}$ inches; as $\frac{6}{7}$ equals $\frac{12}{14}$, then bisect the space $\frac{6}{7}$ $\frac{7}{7}$ on the line A O, Fig. 71, as shown by the line $\frac{13}{14}$ $\frac{13}{14}$, which will be $\frac{13}{14}$ inch. By using the method shown in Fig. 71 any fractional part of a given hight can be obtained. If elbows were required for the round pipe it would not be necessary to figure out the circumference, as the stretchout of the pipe would be taken, on which to cut the miter pattern, and would at once give us the desired circumference. Suppose that a leader, the section of which is shown in Fig. 62, was to run

will be noticed that the first hole from the top is 1 inch from the end and the rest of the holes punched every 3 inches, leaving the last hole 2 inches from the end, as shown, and which will be the side where the leader will be crimped. The holes will be punched with a rivet punch, Fig. 73, the punch being a trifle larger than the rivets used, so as to allow the rivets to slip in easily. As leaders are usually cut from 2 foot wide iron, let us suppose that we have a pattern piece of iron before us which is 2 feet long by the circumference or stretchout of the pipe required; the lap used for riveting the leader being $\frac{3}{4}$ inch, set the dividers to one-half of

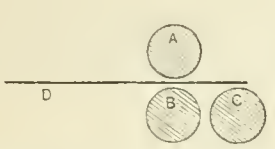

Fig. 74.—First Operation in Forming Round Leader

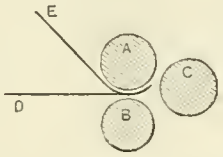

Fig. 75.—Second Operation.

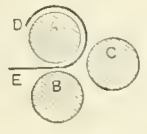

Fig. 76.—Third Operation.

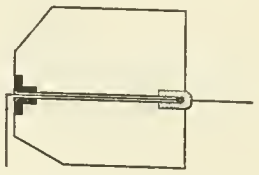

Fig. 77.—Forming Square Leader on Brake.—First Operation.

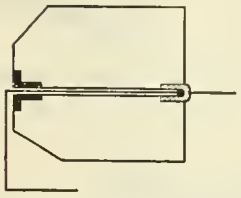

Fig. 78.—Second Operation.

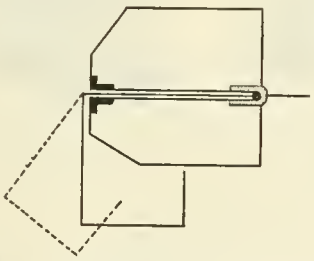

Fig. 79.—Third Operation.

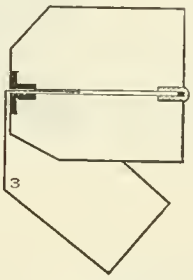

Fig. 80.—Fourth Operation.

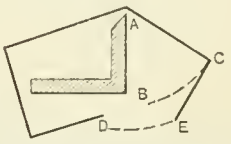

Fig. 82.—Bending Right Angle. First Operation.

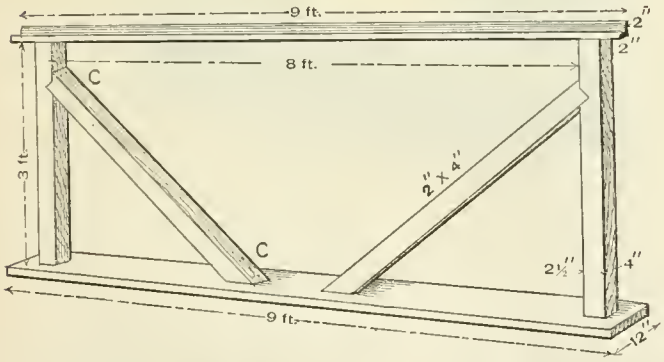

Fig. 81.—Home Made Hatchet Stake, 8 Feet Long.

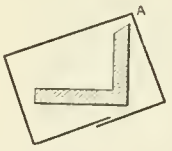

Fig. 83.—Second Operation.

Fig. 84.—Leader Strainer.

THE COUNTRY CORNICE SHOP.

desired length, upon which lay off seven equal spaces, and at right angles to A O draw the line A B, in length equal to 1 inch, as shown; draw a line from B to O, as shown. From the seven spaces obtained upon the line A O, as shown by $\frac{1}{7}$, $\frac{2}{7}$, $\frac{3}{7}$, $\frac{4}{7}$, &c., draw lines at right angles to A O, intersecting the line B O. Then will $\frac{1}{7}$ $\frac{1}{7}$ represent $\frac{1}{7}$ inch, $\frac{2}{7}$ $\frac{2}{7}$ represent $\frac{2}{7}$ inch, $\frac{3}{7}$ $\frac{3}{7}$ represent $\frac{3}{7}$ inch, and so on until the full inch is obtained. Then will $\frac{6}{7}$ $\frac{6}{7}$ in Fig. 71 represent $\frac{6}{7}$ inch, to be added to the 18 inches necessary for the circumference of a 6-inch pipe.

Suppose the circumference was desired of a pipe $5\frac{1}{2}$ inches in diameter, then multiply $5\frac{1}{2}$ inches by $3\frac{1}{7}$, and the result would be $17\frac{2}{7}$ inches; $\frac{2}{7}$ $\frac{2}{7}$, shown in the diagram in Fig. 71, would represent the $\frac{2}{7}$ inch desired. Then again if the circumference of a pipe was re-

down straight, no elbows being required; then knowing the size the leader is to be, no drawing would be required, the stretchout being figured thus: size of leader 3 x 4 inches; 3 + 4 + 3 + 4 + $\frac{3}{4}$ lap = $14\frac{3}{4}$ inches, including lap.

Punching the Leader.

Fig. 72 shows a strip which is used for marking off the rivet holes on the pattern when making leaders. In making strong, substantial pipe it is advisable to punch the holes before the leader is rolled up, and have the holes not less than 3 inches apart. To get the holes on one side of the pattern the same as on the other, so that they will meet when rolled or formed up, cut a strip of iron 2 inches wide by 2 feet long, or as long as the joint of pipe, and divide into spaces as shown in Fig. 72. It

$\frac{3}{4}$ inch, which is $\frac{3}{8}$ inch, and mark a line upon each side of the leader pattern where the holes are to be punched. Now take the strip shown in Fig. 72, and place it upon the pattern of the leader so that the center of the holes will come directly upon the two lines just marked, one at each side. Care should be taken not to reverse the strip when marking the holes upon the opposite sides of the pattern, otherwise they will not meet when rolled or formed to shape.

Rolling the Leader.

In Figs. 74, 75 and 76, A and B represent the sections of the front rolls of a stove pipe former and C, C and C in the same three figures the rear or back roll, which is raised or lowered to give the pipe the desired curve. If a sheet was run through the rolls as in Fig. 74 it

would run out straight at the other end, showing that the rear roll C is the roll which forms the pipe to the required circle. Let C in Fig. 75 represent the roll raised to its proper position to obtain the circle required.

When rolling the leader as in Fig. 75 place the sheet D in the position shown and turn the handle of the roll until the rolls grasp the sheet about ⅛ inch; now hold the handle steady with the right hand and raise the sheet with the left until it has the position shown at E, Fig. 75; this at once gives the small curve as shown and allows the sheet to pass up over the rear roll C. The handle is now turned until the leader has the required circle. If the tinner has the service of a stove pipe former, having what is called a slip roll, then the roll A, in Fig. 76, can be raised at one end and the pipe drawn off after it is formed; but if an old style roller is in use, then when the pipe has the position as shown at D, Fig. 76, the fingers or a piece of heavy metal bent V shape should be placed between the pipe and top roll, and turning the handle, draw out the iron at D, so as to prevent it from again entering between the rolls and until the side E has passed through. Should an old style roller be in use, it is well to raise the back roll C a little higher, thereby making a smaller circle, so as to compensate for the drawing out at D as before explained. After the leaders are all rolled they are riveted, using burrs if desired, and then crimped and soldered together in the usual 10-foot lengths.

Bending Square Leader.

In Figs. 77, 78, 79 and 80 are shown enlarged sections of a country cornice brake, previously described, which will be used to bend off the square leader, in which there are four operations required. Let us suppose that the leader has the shape shown in Fig. 62, and that the seam is to be at B. After the bends are dotted off on the sheet, place it in the brake and make the first bend as in Fig. 77; draw out the sheet to the next dot and make the second bend as in Fig. 78; then again draw out the sheet to the third dot, and make the third bend as shown in Fig. 79. When making the fourth bend, shown in Fig. 80, it will be noticed that the bottom of the leader strikes against the bottom of the brake; therefore after making the third bend, shown in Fig. 79, draw it back again as shown by the dotted line in the same figure. Draw out the sheet to the fourth dot, and make the fourth bend as in Fig. 80. A hatchet stake will now be required, upon which to make the bend 3, Fig. 80, square.

A Home Made Hatchet Stake.

Fig. 81 is a perspective view of a home made hatchet stake, 8 feet in length. The leader is but 2 feet in length, but the object in making the stake 8 feet long is so that it can be used for making the different bends in a molding 7 feet long, if so required. The construction of the stake shown in Fig. 81 is clearly shown. It will be noticed that the base board is 1 foot wide by 9 feet long by 1 inch thick, upon which the 2½ x 4 inch upright joists are placed, 3 feet in hight, braced with 2 x 4 inch split joists on the inside, and nailed or screwed, as shown at C C. Obtain a piece of angle iron ¼ x 2 x 2 inches, and 9 feet in length, made perfectly straight, and screw it upon the upright joists, as shown. The top edge of the angle iron should be filed off so that it will appear as shown at A, Fig. 82. When bending off the angle of the leader above referred to, place the leader in the position shown in Fig. 82, and press down the corner C, which will then make a sweep, as shown by the dotted lines C B and E D, Fig. 82, and will look when finished as shown in Fig. 83.

When making the bend A, Fig. 83, the corner will be rather round. To obtain a square corner use the wooden mallet. Do not use the hammer, as the edge A of the angle iron would be flattened. The method used for the square leader would be followed in forming the octagon leader, Fig. 64. Before riveting the square leader it should be first tacked and soldered, care being taken that the pipe is not lopsided. After the joints are soldered and riveted they are put together in the usual 10-foot lengths.

Fig. 84 is a galvanized wire strainer, which is placed over the inlets of leaders to prevent them from stuffing up. They can be obtained from 2 to 12 inches in diameter.

Cutter.

From H. M. Sanders, *Washington, D. C.*—While it is not always best, perhaps, to disturb traditions handed down to us, they may sometimes open up a fruitful source of inquiry as to whether some of our traditional phrases are not misnomers and out of place—or, perhaps, out of date. Take, for example, this simple but traditional word "cutter." We know—that is, the trade knows—what it means as applied to a department in the sheet metal industry. The craft generally recognize it as expressing an important position in the trade. A firm advertises for a cutter, but they want a man who is able to lay out and develop patterns. So a man who advertises to fill a position as cutter has the same end in view. As in neither case do they advertise for the purpose of filling a position in the cutting room of a cornice shop, so in neither case, as it seems to me, does the term or word cutter express fully what they want. As a fact, the term cutter simply expresses the idea of cutting out work from a pattern, and not the development of that pattern. The simple act of cutting a pattern is one thing and the laying out and developing of that pattern another thing. The former, in a certain sense, is a mechanical process, while the latter is a mental process to the extent of laying out and planning the work. In other words, one requires practical knowledge as distinct from the other, which requires theoretic knowledge. While a man may become a good cutter in its true sense when he has had the necessary hand and eye training, he may know nothing about laying out and developing patterns. On the other hand, a man may understand the theory and be able to lay out and develop patterns and yet be the poorest kind of a cutter. Both elements combined, theoretic and practical knowledge, are essential; not surely to make simply a good cutter, but an expert in the development of patterns and laying out work. What might do in former times when the cornice busi-

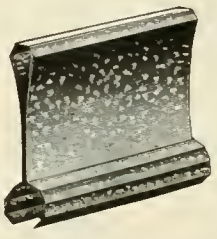

Fig. 2.—*Block No.* 2.

Fig. 3.—*Block No.* 3.

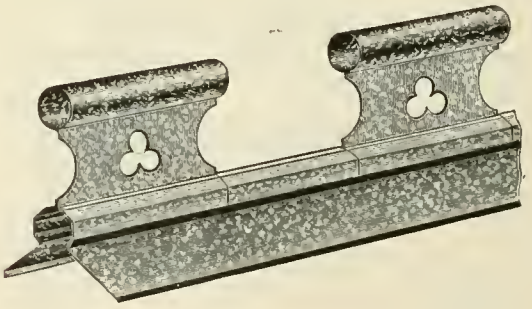

Fig. 4.—*Blocks in Place on Ridging.*

GARRY RIDGING BLOCKS.

The Garry Ridging Blocks.

We illustrate in the accompanying engravings new designs of the Garry ridging blocks manufactured by the Garry Iron & Steel Roofing Company, Cleveland, Ohio. These blocks can be made from either painted or galvanized steel, and can be adjusted on the ridging to any position by simply pressing the apron of the ridging together. This, it is pointed out, frees the block so it can be moved wherever desired, and as the aprons again spring back to place the block is held securely, no solder being required. Figs. 1, 2 and 3 illustrate the three designs of the blocks, while Fig. 4 shows block No. 3 in place on the ridging. The blocks are made to fit style B bridging of the Garry Iron & Steel Roofing Company, 2½-inch roll, although they can be made to fit the other sizes if desired. They also make blocks to fit a plain ridging.

ness was in its infancy, and a man made his own patterns and got out the work himself, seems meaningless and out of place now under later and newer conditions of trade, when business is brought down to system with its various departments and classified work.

There is the soldering room, machine room, stamping room, cutting room and drafting room. Usually when any help is required in any of these departments, outside of the drafting room, there goes out an advertisement for a corniceman. But when it comes to filling a vacancy in the drafting room, by common consent, or tradition, or whatever you may call it, a cutter seems to fill the bill; and yet, if there is any one of these departments more than another that needs a corniceman to meet fully its requirements, it is the drafting room. We would not think of advertising for a draftsman to fill a position in the cutting room, but it is less out of place than to advertise for a cutter to fill a position in the drafting room. One seems about as sensible as the other, and, laying aside the traditional aspect of the case, both seem out of place, if not absurd.

FLASHINGS.

E. C. Atwater & Co., Springfield, Mass., have been awarded the contract on the Y. M. C. A. Building in that city for the copper cornice and base, galvanized iron, tin and metal ceiling. The work will require 3500 pounds of 16-ounce copper.

Alfred Frommhold, 71 Wells street, Chicago, has removed his cornice works to more commodious quarters at No. 72 on the same street.

The Berger Mfg. Company, Canton, Ohio, issue to the trade their 1894 catalogue and price-list, which is the eighth annual publication of the sort. This firm are the well-known manufacturers of Berger's patent eaves trough hangers, corrugated and plain conductor pipe, ridging, capping, cornice, window caps, &c. They likewise make steel roofing, corrugated iron, steel brick, rock faced stone, metallic shingles, patent ceilings and shutters. In a preliminary announcement to the trade they mention that they have, since issuing their seventh catalogue, added to their already large factory the latest improved machinery for the manufacture of sheet metal goods. The first part of the volume is devoted to eaves troughs and eaves trough hangers, as well as conductor pipe, conductor hooks, &c.; then come miscellaneous goods such as cut offs and strainers. American roofing plates are noted, as well as ventilators of various sorts. Ridgings and crestings are given several pages with illustrations. Then come cornices, window caps and finials, of which many varieties are illustrated. The second part of the volume is devoted to the roofing section. After rules for measurement and directions for applying, together with a summary of the advantages of this class of roofing, attention is given to the various roofings that the Berger Mfg. Company make. Corrugated iron, metallic shingles, siding and ceiling, &c., follow, and at the end notice is made of fire proof doors and shutters and miscellaneous goods. An alphabetical index facilitates reference. The pamphlet is bound in red paper with the company's name stamped on the front cover.

An iron roofing factory is contemplated at Webster City, Iowa, by Charles Crary and other residents of that place. They propose to erect a one-story building, 200 x 60 feet, and manufacture corrugated iron, metal roofing, metal shingles, ceilings, cornices, steel brick, &c.

The skylights in Meurer Bros.' new tin plate works in Brooklyn are composed of wire glass. This material makes them impervious to the missiles of the small boys of the neighborhood, who have already tried their hand on the inviting expanse of glass without any damaging effect.

The following is an interesting experience on the connection of tin and copper in roofing that has come under the notice of Borkel & Debevoise, 42 and 44 East Houston street, New York, who were called upon to make repairs. The valleys on a large building were originally of copper and were found too narrow to render good service. The tiling of the roof was taken off in order to increase their width. This was done less than two years ago, when, owing to the cost of copper, a heavily coated tin plate was used. It is now necessary to do the work again, as the action of the copper not only destroyed the tin coating, but made the plate look like a piece of old lace. The copper is still in good order, so that there was no difficulty in opening the seam and soldering to the new copper, which is now being used to widen the valley.

The Kansas City Metal Roofing & Corrugating Company, Kansas City, Mo., distribute an illustrated circular of the goods they handle. At the beginning of the catalogue is a copy of the United States Standard Gauge adopted last year, which will be appreciated by the trade. The first goods noticed are corrugated iron, illustrations directing attention to the 2½-inch plain edge corrugated iron in sheets 5 to 10 feet long and 26 inches wide. Sectional views show the full size of the corrugations. An assortment of ridge caps are next noted. Then come other styles of corrugated iron, beaded iron, weather boarding, pressed brick, standing seam roofing, V-crimped roofing, &c. Among these notice is made of the curved corrugated iron used for arches and awnings, &c. Corrugated iron laths are also mentioned, being illustrated and described. Under metallic shingles are shown the Walters, Cooper's Queen Anne and the Hamaley. Eave troughs, conductor pipes, hooks and hangers are noted; a variety of roof crestings, likewise ornamental iron finials. These goods are followed by fencings, shutters, felt roofing, &c. At the end is a telegraphic cipher that will facilitate ordering goods by wire.

The Knisely & Yeldham Roofing Company, 68–74 West Monroe street, Chicago, have the contract for the copper cornice work, skylights and tin roofing for the Haymarket Theater, 161–179 West Madison street.

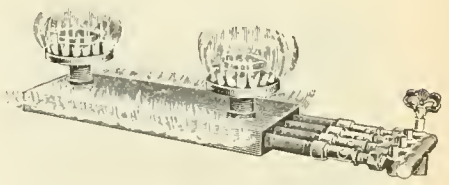
According to careful estimates, three hours of close study wear out the body more than a whole day of hard physical exertion.

Gas engines are growing in favor in Australia for factory purposes. The colony of Victoria alone possesses more than 300 of these engines.

Advices from the East state that Japanese coal is attaining some considerable success. A recent shipment to Bombay, India, was found very satisfactory, as its cost is nearly 50 per cent less than that of Welsh coal landed at that port, while the consumption is only 8.50 per cent. higher.

Cooking Burners.

The illustrations herewith show some gas burners made by the Hollands Mfg. Company, Erie, Pa., for use in the fire chambers of ordinary cooking stoves or ranges. They are specially made for the use of natural or fuel gas and are



Cooking Burners.—Fig. 1.—Sectional Burner with Four Supplies.

adjusted to a pressure of about 3 ounces in operation and are not adapted to the low pressures ordinarily found in city mains for illuminating gas. Fig. 1 shows a sectional four flame burner with controlling keys and air mixers at the right end, so arranged that a flame can be used under either or both cooking holes, and a flame lengthwise on either

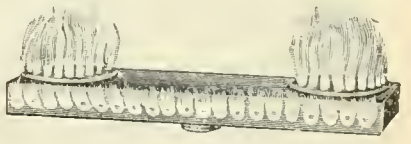


Fig. 2.—Burner with One Supply.

or both sides of the burner. Fig. 2 shows a burner with but one mixer and supply, and with flames along each side of the burner and under both of the cooking holes. Fig. 3 shows an air mixer such as is used in connection with many different styles of gas

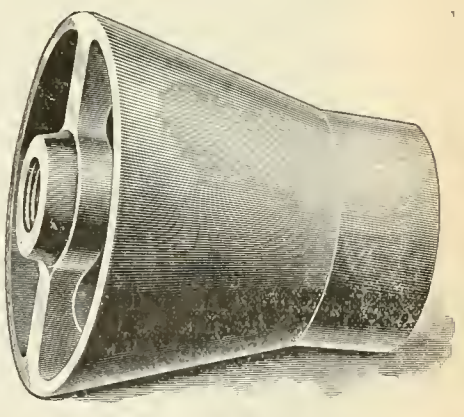

Fig. 3.—Air Mixer.

burners. These goods are made in various sizes to suit different requirements.

The Panama Canal is again becoming a topic of interest in the French capital. Although nothing definite has been settled it is believed that a new company has been formed for carrying on the work. M. Bartissol, a famous contractor, and M. Eiffel are said to be the moving spirits of the undertaking.

STEAM AND HOT WATER.

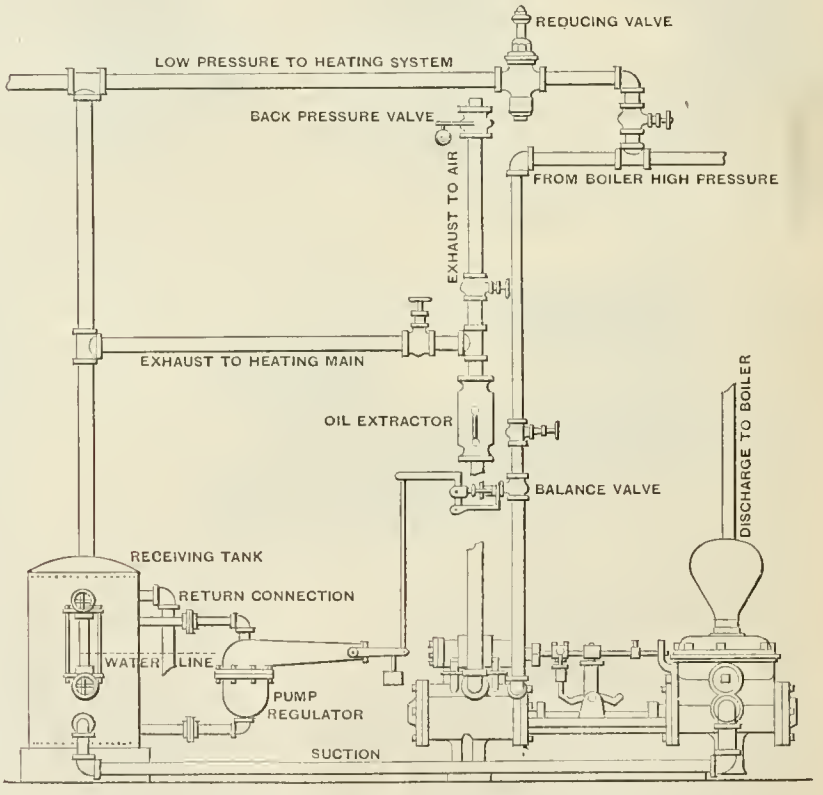
The Value of Exhaust Steam for Heating.

BY HELIOS.

It is not well known, yet it is a fact, that a building can be warmed by exhaust steam with a less cost for coal than it can be heated with a low pressure gravity return circulation apparatus, and the higher the pressure is carried on the boiler the less coal it will take to do the heating. The system of piping, however, should be so arranged that there will not be over one to two pounds back pressure on the engine or pumps, and this can be done in a heating plant for a building of any size. At the present time all large office buildings have steam pumps for the elevators and engines for electric lighting, and the exhaust steam from all pumps and engines should be used for the heating of the building, as the exhaust steam is too valuable to throw away. In placing heating apparatus for exhaust steam heating the piping must be of ample size to deliver the steam to the radiation without any back pressure on the engine or pumps, and this can be done by the size and arrangement of the main exhaust steam pipes.

In an exhaust steam heating apparatus, to receive the full benefit of all the coal consumed under the boiler, all the exhaust steam must be used and all condensation returned to the boiler without loss. The exhaust steam as it leaves the engine or pump must first pass through an oil extractor, as shown in the illustration, to remove all the cylinder oil from the steam. If the cylinder oil is allowed to enter the piping it will bake on the piping and radiation and decrease the amount of the radiation of heat, and if the oil is allowed to enter the boiler it is liable to cause the boiler to prime and the sheets to blister. Another serious fault is that it will cause a disagreeable odor to the steam or air that may blow into the building in removing the air from the radiation.

In connecting up the feed water heater it is very necessary that valves are placed in all connecting pipes, also that a by pass is made around the heater, so that at any time repairs have to be made to the heater the valves can be closed in the pipes to the heater, and the by pass opened, allowing the steam to pass around the heater and permitting repairs to be made without shutting down the plant. After the steam has passed through the feed water heater, take off two branch pipes, one to connect to the heating system and one to discharge the exhaust steam into the air. The main exhaust pipe should be 25 per cent. larger in area than the combined area of all exhaust pipes connecting to it. In the pipe that discharges the exhaust steam into the air place a back pressure valve, and into the pipe that connects to the heating system a gate valve. The back pressure valve should be set so that it will open when the pressure is above two pounds per square inch on the heating system. For furnishing steam to the radiation at such times as the engine or pumps are not in operation, and for supplying steam, if there is not enough exhaust steam to fill the radiation, connect a pipe direct from the boiler or from the high pressure steam main to the main exhaust pipe, and place in it an automatic reducing valve, this valve to close if there is one pound pressure on the heating system, and to open if below that pressure. If there is exhaust steam enough from the engine to fill the radiation and keep one pound pressure on the heating system, the automatic reducing valve will keep closed; if there is not enough exhaust steam, the automatic reducing valve will open and supply the necessary amount of steam to keep the pressure on the heating system at the pressure at which the reducing valve is set.



Exhaust and Direct Steam Connections, Receiving Tank and Pump.

If the engine is shut down the reducing valve will open and supply direct steam to the radiation; as soon as the engine is started and the exhaust steam increases the pressure the reducing valve will close. If the engine is running and there is not enough exhaust steam to fill the radiation and the reducing valve is supplying steam direct from the boiler, should there be an increase in the volume of exhaust steam the reducing valve will close, and if the increase of exhaust steam continues the back pressure valve will open, relieving the pressure and closing as soon as the pressure is below 2 pounds.

On the end of the exhaust pipe that discharges the exhaust steam into the air always place an exhaust condenser head. This is placed for a double purpose: first, to prevent the condensation being thrown out on the roof of the building; second, to save all the condensation and return it to the boiler. To have an economical power and heating plant great care must be taken not to allow any steam to be wasted, and the condensation from the feed water heater and radiation, condenser head, cylinder cocks and drips of every and all kinds must connect into the return tank, as every pound of hot water lost means so much more coal to operate the plant. Another great loss is allowing the main steam and exhaust pipes to be uncovered. It will cost $80 per year for each square foot of heating surface on a main steam pipe that is not covered in a plant that is in operation 24 hours per day. Connect all return pipes and all drip pipes to a receiving tank, connect the suction pipe of a direct acting steam pump to the receiving tank and place the pump so that the condensation will flow to the pump.

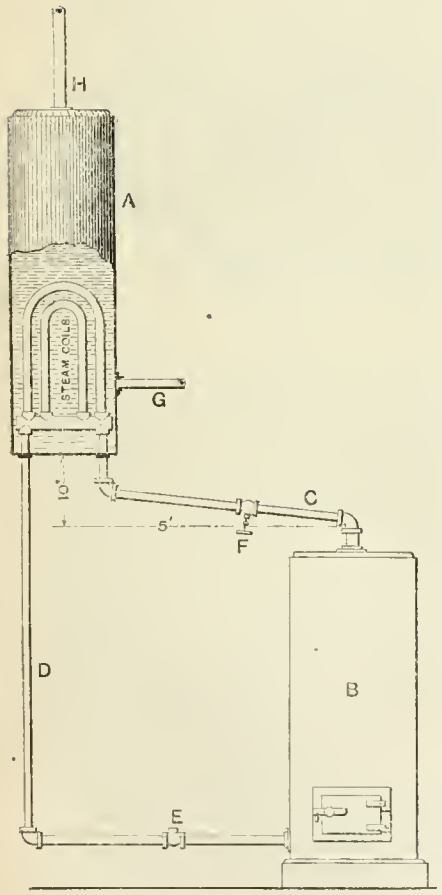
An automatic pump regulator is connected to the receiving tank and to a valve in the steam pipe to the pump. As the condensation returns to the receiving tank, the automatic regulator will open the valve in the steam pipe to the pump, starting the pump, drawing the condensation from the receiving tank and forcing it through the feed water heater and into the boiler. As soon as the pump lowers the water in the receiving tank to the water line the automatic regulator closes the valve in the steam pipe to the pump, stopping the pump. In ordinary weather the pump regulator will control the speed of the pump, so that it will run all the

time and keep the water at the water line in the tank. A plant connected up as has been explained above will work perfectly and economically.

In a building with an electric light plant, using the exhaust steam for heating, where all the exhaust steam can be used and none is wasted, the electric lighting will cost nothing, as it will cost less for coal to run the electric light plant than it would to heat the building by a low pressure gravity return circulation apparatus. The engine acts as a reducing valve, and the loss by condensation in the engine is very slight. It will not take any more coal to run the engine than it will take to allow the steam to pass into the heating system through a reducing valve.

Returning Condensation to Boiler.

From Y. J. W., *Raleigh, N. C.*—Will *The Metal Worker* kindly inform me if a steam boiler connected with a



Returning Condensation to Boiler.

100-gallon boiler, as shown in the illustration, will heat the water and operate successfully? The question is whether the condensed steam or water in the heating coil will return to the steam boiler, which carries a pressure of 80 pounds. In the illustration, A is a 100-gallon water boiler, B is a 15 horse-power steam boiler, C is the steam pipe, D is the return pipe, E is a check valve in the return pipe, F is a globe valve on the steam pipe, G is the cold water pipe to the hot water boiler and H is the hot water pipe leading from it. A high pressure boiler is to be used, and if the condensation will not return against an 80-pound pressure the system will not be satisfactory. If a steam heating job is constructed on the usual low pressure gravity system, how high can the pressure on the boiler be raised before the condensed steam in the return pipe will fail to return to the boiler? Why will not the condensation return to a boiler carrying a 60-pound pressure as well as to one carrying a 10 pound pressure? Is the pressure the same where the return pipe enters the boiler as it is at the dome? If not, what is the difference?

Answer.—The condensation in the system shown will return to the boiler without difficulty if it is properly piped, and the check valve will not be needed. The pipes should have a positive pitch and there should be no traps. The coil should expose 1 square foot of heating surface for every 5 gallons of water. In a correctly piped heating system where the return does dip below the boiler the condensation will not be prevented from returning to a boiler carrying any pressure that the system will stand. The pressure is the same practically at the flow and return, except that the weight of the water bears on the return.

Crane Company.

Crane Company, Chicago, Ill., have added another to the number of branch houses and supply depots already maintained by them in various parts of the United States, by leasing the premises at 122 to 130 Center street, corner of White street, New York. They have the street floor, floor above and basement, each 80 x 95 in size. The offices, occupying a part of the street floor on the Center street side, are trimmed in light hardwood. The balance of the floor is fitted up with appropriate bins and shelving for carrying a stock of brass and iron fittings, &c. The floor above is for much the same purpose, while pipe, pipe machinery and the heavier classes of goods are provided for in the cellar. The company, established in 1855 and incorporated 10 years later, manufacture extensively at their several factories in Chicago and Pittsburgh, wrought iron pipe, malleable and cast iron fittings for steam, water and gas; also brass and iron valves, cocks, gate valves and hydrants, steam and gas fitters' tools, engineers' and engine builders' supplies. Among their branch houses are those at Philadelphia, Pa.; Omaha, Neb; Kansas City, Mo.; Minneapolis, Minn.; Los Angeles and San Francisco, Cal.

Fusible Plugs.

From Boiler Maker, New York.—In answer to "Steam Fitter," in *The Metal Worker*, February 10, the melting point of fusible plugs should be at a temperature which corresponds with the temperature of the steam at a pressure which the boiler is limited to carry. They should not soften under the temperature of the ordinary steam pressure carried. Pure tin is considered most reliable, as alloys become less fusible in use and are more readily coated. Here are some alloys with the temperatures at which they soften and melt:

Two parts tin and two parts lead soften at 365° F. and melt at 372° F.

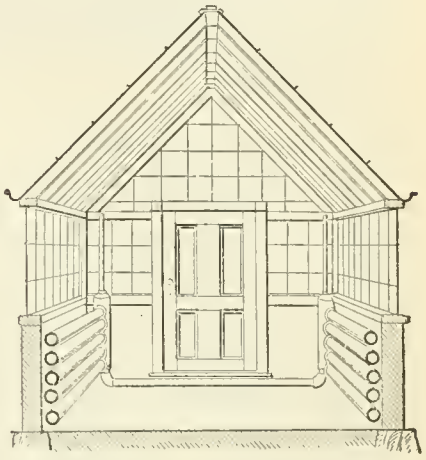
Two parts tin and six parts lead soften at 372° F. and melt at 383° F.

Two parts tin and seven parts lead soften at 377½° F. and melt at 388° F.

Two parts tin and eight parts lead soften at 395½° F. and melt at 408° F.

Heating Greenhouse With Hot Water.

From OLIVER TWIST.—Hot water heating, like every other business, has its difficulties, which can only be overcome by experiment and thought. The difficulty in the case which is described and illustrated was to continue the circula-



Heating Greenhouse with Hot Water.—Fig. 1.—Method of Passing Door.

tion of hot water past a doorway in a greenhouse which is heated by wall coils. An annex had been made to the greenhouse, and the hot water boiler then in use being thought too small to

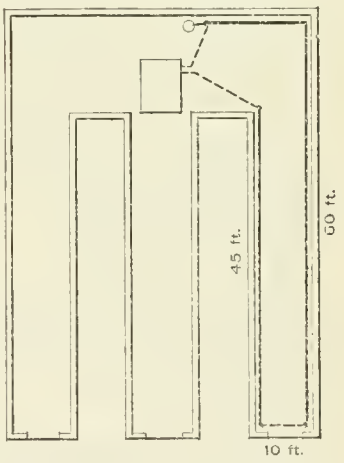


Fig. 2.—Plan of Greenhouse.

properly heat it, in addition to what it already had to do, it was decided to make a water back similar to that shown in Fig. 3, which shows an elevation and plan of it. It is made of five pieces of 1¼-inch pipe, connected with

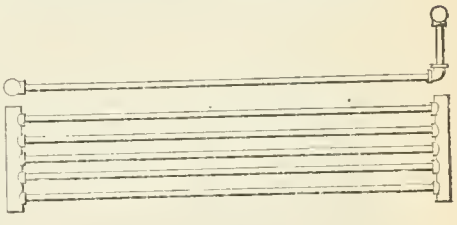

Fig. 3.—Plan and Elevation of Auxiliary Heater.

elbows and headers, as shown, being 5 feet long. This is placed in the furnace at an inclination of about ½ inch to the foot at or near the top of the fire box. This supplies about 600 feet of 1 inch pipe, arranged in wall coils five pipes high, as may be seen by reference to Figs. 1 and 2. Fig. 2 shows a plan of building in which can be seen the location of boiler. Fig. 1 shows the

method of getting past the doorway. A 1¼-inch pipe is taken from the bottom of the header and continued down to and across the floor, then up and into the bottom of the header on the opposite side of the door. From the top of each header is taken a ½-inch pipe, which runs up to a hight somewhat above the level of the expansion tank, to allow for expansion of the water without overflowing. This plan gives good satisfaction.

HEATING NOTES.

THE LATEST POSTAL TRAVELER sent out by the United States Heater Company, Detroit, Mich., carries on the back a broken view of the Hecla steam heater, showing clearly all its features of construction. On the front is presented a scene from Iceland, features of which are Mount Hecla, polar bears and walruses. The accompanying text tells of the tempering influence of Hecla in this arctic region, and is illustrative of the efficiency of the boiler of that name.

A HANDSOME CATALOGUE is issued in the interests of the Royal hot water heating apparatus manufactured by Hart & Crouse, Utica, N. Y. The volume, containing 20 pages, is bound in tinted cardboard with stamped title, and has for frontispiece a wash drawing showing in a conventional way the awarding of the wreath of victory to the Royal heaters. The pamphlet gives general observations on hot water heating with special reference to the advantages of the Royal system. Then come cuts showing general, broken and sectional views of the Royal heaters. After them are tables of sizes, capacities, prices, &c.; then directions for using and instructions for setting up Royal hot water heaters, the whole closing with a brief list of some of those who are using this apparatus.

J. D. & C. C. LINCOLN, 236 Water street, New York, are making preparations for an active campaign in the heating business with the line of steam, hot water, hot air and combination goods made by the Fuller & Warren Company, Troy, N. Y.

CARLETON W. NASON of the Nason Mfg. Company, 71 Beekman street, New York, manufacturers of ten to one Equator steam and Gulf Stream hot water boilers, is making a tour of the West Indies.

WARREN C. JOHNSON of Oskaloosa, Iowa, has leased his foundry and machine shop to George Greasby. Mr. Johnson will continue the manufacture of hot water heaters and coal drills.

THE FUEL GAS & MFG. COMPANY of Pittsburgh, Pa., send us a circular of the Whyssall patent boiler burners, designed for use in connection with steam boilers. This burner is only one of many which they make in addition to their line of heating and cooking apparatus.

THE LOVE MFG. COMPANY, Corry, Pa., send us a catalogue of their Vulcan fuel gas burners, which are said to work with a pressure as low as one ounce by enlarging the gas orifice in the mixer. They are made for heating stoves and cooking stoves. A special sectional burner is made for furnaces, steam and hot water apparatus, so that one or five sections can be operated as desired.

LAST TUESDAY John A. Scolly, 70 and 72 Myrtle avenue, Brooklyn, received from the foundry of John Davies, Second avenue and Eleventh street, 60 of his improved hot water boilers. His men are engaged in erecting the heating plants in a number of residences and greenhouses.

THE GRIFFITH HEATING AND VENTILATING COMPANY and Wicks & Hughes, two of the largest concerns in eastern Washington, have consolidated. The members of the new firm are J. H. Griffith, George H. Hughes and George E. Clark, and will be styled the Griffith Heating and Plumbing Company, located at 110 Howard street, Spokane.

THE NEW HAVEN HEATING & PLUMBING COMPANY, New Haven, Conn., issue a catalogue illustrating and describing the Shearlock hot water heater of their manufacture. The first illustration is a broken view of the boiler set in brickwork, and shows clearly its constructive features, indicating the shell water space and the drop tube arrangement of surface. The next is a sectional view through the middle of the apparatus. Together with the illustrations are given full descriptive particulars speaking of the general advantages of hot water heaters, and also of the particular merits of the Shearlock. A table of sizes and prices is given, together with testimonial letters from many of those who have used the apparatus.

H. P. BLAIR & Co., South Bend, Ind., will handle the United States Heater Company's Hecla steam and Capitol hot water heaters.

Specifications for Heating and Ventilation.

In the absence of previously prepared drawings and itemized specifications there is a great tendency in the drawing of proposals, descriptions or specifications for heating and ventilating work to make them in all things too general. While this is manifestly true in the case of ordinary steam heating, it is most noticeable in many instances where contracts are made for the installation of the blower system. This is doubtless due in a great extent to the lack of knowledge of and experience with this system, which is still further affected by the fact that there exists no uniformity in the manner of designating the sizes of fans, while heaters are frequently specified of given "capacity" and engines of "ample" size. In fans of the same general design there is but little difference in efficiency, but all similarity of size or capacity is covered under a system of consecutive numbering, or by such indefinite descriptive appellations as 5 x 7½, B10, 120 inches or 10 x 5. Under such a classification one would naturally expect the capacity of the fan to serve as an indication of its size, but here we find the same fan having different capacities like a steam engine according to the speed at which it is driven. Even when that is given we are told by the manufacturer, if we press him to it, that the tabulated capacity may be seriously affected by the unknown resistances that may exist in a system of ducts or pipes over whose construction or design he has had no control. And yet, as viewed by the manufacturers this is all proper and only a necessary inconvenience of the business. Air is not like water, in that it is non-compressible, and the comparison drawn between the action of a pump and that of a fan blower does not hold. The pump if it works at all must (like the so-called "positive" blower of the rotary pump type) always deliver a given volume of the fluid passing through it, but the fan blower is automatic; when resistance is interposed the volume delivered and the power required is reduced.

When a fan blower is to be described at all, its type, diameter of wheel, width of wheel and greatest diameter of inclosing shell should be given, together with the size of engine when such is to be provided. In blowers of even reasonably good construction, driven at the speed necessary for heating work, agreement in these points will be indicative of substantially equal capacity, for there is practical accord between different manufacturers in the matter of inlet and outlet sizes, width of fan wheels at their periphery and minor proportions. Heaters for hot blast work vary more radically in design and construction, and choice must be made upon judgment and experience. But the size should be given definitely in the actual number of running feet of given size pipe (almost universally 1 inch) exposed to the air as it passes through the heater. It should not include outside headers or connections or portions of pipes screwed into the faces.

Certainly nothing is better or more satisfactory for the purchaser than a guarantee—that is, where there is somebody of responsibility behind it. A specification or contract containing such a warrant may, of course, with reason, omit much of the detail of description. A fan, engine and heater of "ample" size may then be sufficiently explicit. But let the guarantee be likewise explicit. Let the contractor by all means avoid a legal promise to make the system "satisfactory." What satisfies one man may not another, and the most painstaking care may not be sufficient to secure the approval and the desired payment from a man who sets up "satisfactory to the owner" as a bulwark behind which to hide and avoid his honest debt. Properly, the condition of outside temperature at which a given inside temperature is to be maintained should be specified. But an explicit guarantee to heat to, say, 70° when the thermometer stands at 0° outside may often be a source of serious trouble to the contractor in the matter of securing his payments. With such warm winters as we have recently experienced zero days are rare, and a mutual test of the system under the specified conditions may be exceedingly difficult to secure during the short time that the desired outside temperature continues. There is no reason why the guarantee of any reputable house to heat to, say, 70° in zero weather should not be sufficient, and any owner can reasonably assure himself of the adequacy of the apparatus at outside temperatures above the minimum specified.

In factory heating by the blower system it becomes a matter of particular importance, in drawing a guarantee, to clearly specify or describe the buildings and rooms covered, and to state whether the result is to be accomplished by the use of live or exhaust steam (pressure to be specified) and whether air is to be taken from out of doors or returned from within the building. The blower system is still so novel to many that they are unqualified to judge of the relative efficiencies of different sized apparatus, but the time will soon come when a more general understanding on the part of the public, and greater uniformity in the character of the specifications drawn by experts, salesmen and manufacturers, will result in greater certainty and a clearer comprehension in the minds of all concerned.

PLUMBING and GAS FITTING.

Plumbing at the Baron de Hirsch Trade Schools.

The plumbing classes at the Baron de Hirsch Trade Schools, 225 East Ninth street, New York City, are reported to be in very successful operation. Since their inauguration on January 1, 1893, 40 young men have received certificates of proficiency. All these youths have, it is said, succeeded in obtaining remunerative employment in the trade and are now at work, earning a good livelihood. The plumbing classes are under the able direction of a New York Trade School graduate—Bernard Bedanes—who has organized the course of instruction closely on the lines of that institution. He teaches both the day and night classes, in which there are at present some 40 pupils. There is no fixed period for the course of instruction, but pupils are certificated as soon as in the judgment of the instructors they are sufficiently proficient to merit a diploma. The average time occupied by each pupil hitherto has been six months for the day class and nine months in the evening class. Those attending the evening class are generally employed as plumbers' helpers during the day or in some other business. Some of the graduates from the day plumbing class, however, who are employed in the neighborhood, return, in order to take the evening course, which is rather more advanced in character.

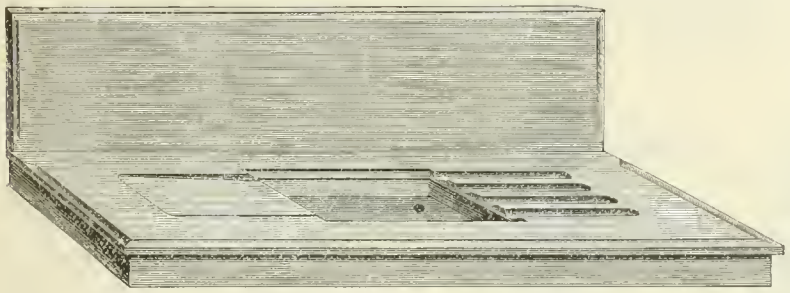
The only drawback in connection with these plumbing classes is the lack of space. This alone prevents their being extended very materially. At present numbers of applicants for instruction are refused on this ground, as there is accommodation for only about 20 pupils at one time. In order to overcome this difficulty it is in contemplation to build a couple of additional stories on to the present structure, giving each trade an entire floor for its operations.

The other trades taught in the schools are carpentry and wood turning, machinist's work and painting, all the classes for which are well attended. The institution is appreciated as a boon by the class for which it was established, namely, poor and friendless Jewish youths of Russian and Roumanian origin.

The Mechanics' Supply Company, 96 St. Peter street, Quebec, Canada, send out a batch of blotters on which is a variety of advertising matter relating to their business, which is in plumbers', gas and steam fitters', engineers' and machinists' supplies. Half of the blotters are printed in English and half in French.

Slate Butler's Sink.

Fair Haven Marble & Marbleized Slate Company, Fair Haven, Vt., are bringing out a new slate butler's sink. The fixture consists of a simple slab of slate, having in the middle a shallow sink of the same material, which drops below the slab. The ends of the slab are either countersunk or corrugated, as desired, allowing a rapid and perfect drainage.



Slate Butler's Sink.

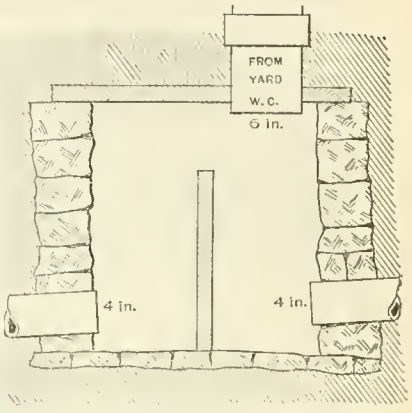
They are made in ten regular sizes' with wall or splash slabs, if desired.

Mayor Lane & Co.'s New Building.

Mayor Lane & Co , 119 Walker and 42–44 Mott streets, New York, dealers in plumbers' materials and gas and steam fitters' supplies, are now consolidating their entire business under one roof by moving into their handsome new building at 128, 130 and 132 White street, the rear of which adjoins their present quarters. In the erection of this building, which is now about completed, the steel skeleton system of construction was adopted. It has been their purpose to make the structure thoroughly modern and fire proof. The front is a combination of cream colored Anderson pressed brick, Warsaw blue-stone and iron, so arranged architecturally as to give a very handsome effect. There are nine stories and a basement, each measuring 60 feet front and 85 feet in depth. The building will be supplied with electric power and light and an electric elevator. Mayor Lane & Co. will occupy the street floor and floor above, together with the basement. The balance will be rented for light manufacturing or similar purposes. The street floor will be reserved for show-rooms and offices. They will have here at least two exhibition bathrooms, tiled and with every detail complete. The offices will be in the rear and finished in antique oak. The remainder of the space will be utilized for sampling their goods. The floor above this will contain their stock of brass goods, earthenware and kindred lines, while heavy goods, including iron pipe and fittings, sinks, cast iron materials, &c., will be kept in the basement. The whole building is admirably lighted both naturally and by artificial means.

Some Poor Plumbing.

In one of his lectures before the plumbing class at the New York Trade School, Chief Instructor John Delehanty used the following illustrations of some defective work which came under his notice. Mr. Delehanty is a practicing master plumber of the firm of Roach & Delehanty, 906 Columbus avenue and 679 Second avenue. Fig. 1 shows a mason work trap with an upright partition in it and having a 6 inch inlet in the top and a 4-inch inlet in the side and a 4-inch outlet. It was discovered



Some Poor Plumbing.—Fig. 1.—A Mason Work Trap.

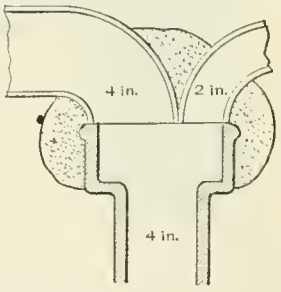


Fig. 2.—An Economical 1.

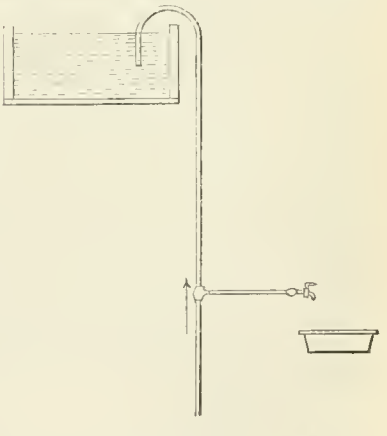

Fig. 3.—Drinking Faucet Syphons from School Sink.

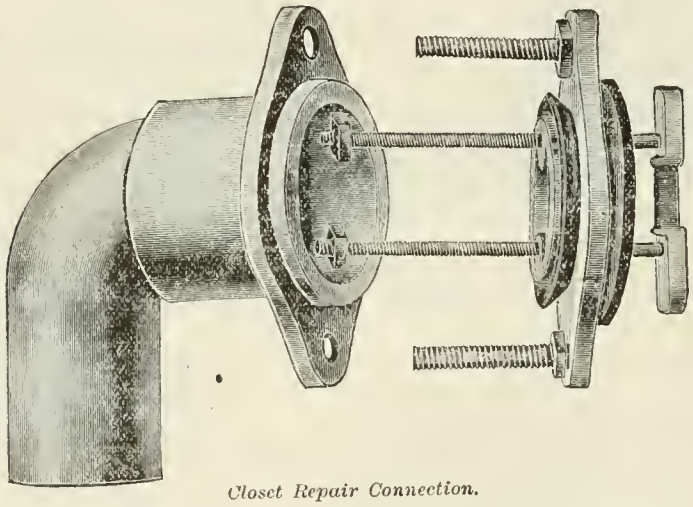
through the bottom inlet becoming stopped and the leakage creating a stench in the cellar. Fig. 2 shows a 3 and 4 inch pipe connecting with the hub of a 4-inch pipe, a "wiped" joint being made of Portland cement. A portion of each pipe extended beyond the hub and a considerable leak resulted from the cement becoming cracked. Fig. 3 shows a school sink on a floor above a faucet used to draw water for drinking. Owing to the water supply pressure failing at times to reach the faucet water was syphoned from the school sink. The supply pipes were so changed that such a result was impossible.

Closet Repair Connection.

The illustration herewith shows a device made by the Phillips Mfg. Company, 219 East Thirty-fourth street, New York, for repairing water closets on which the flush or vent horn is broken. In the past a new closet has been necessary in case of such an accident, and the expense has been no inconsiderable annoyance. The method of using the device given by the manufacturers is to file or chip with a sharp chisel the broken horn until a smooth, flat surface is obtained. Then the loose bolt is unscrewed from the crossbar, which is inserted in the horn and the bolt replaced, leaving the crossbar always in a vertical position. Next pass over the ends of the bolts the brass flange, which has a rubber washer made to cover both sides, and screw the nuts down on the bolts so that the flange bears evenly against the closet, making a tight joint which it is claimed will last for years without the use of lead or putty. These bolts can now be cut off if desired. The brass coupling, which is secured to the flush or vent pipe by a wiped joint, is now secured to the flange against the rubber washer by the flange bolts. A rubber coupling is also made for use with closets where the original connection has been made with rubber. It is claimed that by means of this device many expensive water closets that have been accidentally broken can be retained in use and give perfect satisfaction.



Closet Repair Connection.

We receive from the H. Mueller Mfg. Company of Decatur, Ill., a catalogue of their specialties in brass and lead for water and gas. In cities where a high water pressure is carried a hole larger than 1 inch is not allowed to be made in the pipe where a branch connection with several feeders taps the main and supplies a larger pipe. They furnish these branches with heavy lead pipe connected to them by a wiped joint and with a corporation stopcock on the other for water companies that do not employ a plumber.

Manhattan Mosaic Marble.

A material that is furnished in all of the various forms to which marble and granite are adapted is being made by the National Mosaic & Marble Company, 13 West Forty-second street, New York, and is known as Manhattan mosaic marble. It is made of marble chips and pure Portland cement subjected to a pressure of from 10 to 20 tons. Columns, vases, table tops, wainscoting, floor tiles and stairs and balustrades give an idea of its adaptability. Tiling and slabs are made with designs in different colors in addition to the mosaic effect of the ground work. It is made into slabs for all the purposes for which plumbers use marble, slabs for lavatories, water closets, urinal stalls, and is also made into bathtubs, sitz baths and lavatory bowls. A catalogue is now being prepared giving illustrations and descriptions of the marble and its uses. The floor in the New York Produce Exchange is laid with these tile. The window sills, steps and columns of the St. John's College of Brooklyn and the floors of the Carter Building in Boston, the Club House at Saratoga Springs and the Carnegie Library at Pittsburgh, are all tiled with the Manhattan mosaic marble. The company have showrooms at 159 La Salle street, Chicago, and works at Stamford, Conn. On May 1 the New York office will be moved to the Metropolitan Building, at Twenty-third street and Madison avenue, where a fine show of their goods will be made.

TRAPS AND VENTS.

The committee from the Plumbers', Gas and Steam Fitters' Union of Buffalo, N. Y., which waited upon the master plumbers when in convention in that city recently, reported to the union, and further effort will be made to arrive at some agreement with the master plumbers to govern the number of apprentices employed.

C. D. Rodgers and John P. Freeman have formed a copartnership in the plumbing business, under the firm name of Rodgers & Freeman, with headquarters in the Glandon Building, at Mexico, Mo.

"We are making all styles and sizes of aluminum pantry and kitchen sinks; our catalogue of them is not yet ready for distribution, but we will be pleased to quote prices on receipt of inquiry," is the announcement on a postal card that is being sent to the trade by Manager John Pearce of the New York office, at 43 Beekman street, of the W. S. Cooper Brass Works of Philadelphia.

M. J. Gorman is traveling in New York and R. McGuire in New England in the interest of the Henry McShane Mfg. Company, 625–627 Sixth avenue, New York. They talk the Lucania syphon closet and the Egyptian enameled baths, also an extensive line of standard goods. An invitation is given to visit their New York showroom, where some handsome goods are displayed and two bathrooms are fitted up with considerable elegance.

Harry M. Rendell, formerly connected with a plumbing establishment in Utica, N. Y., has accepted the position of estimating clerk with Leonard D. Hosford, 43 Beekman street, New York.

Peck Bros. & Co., the well known manufacturers of plumbers' supplies, are preparing at their factory, New Haven, Conn., what will be, perhaps, the most elaborate showroom in this line of business in the country. The room is 60 x 70, well lighted and finished in birch, which is permitted to retain its natural color. The apartment is now being fitted up with a full line of the goods manufactured by Peck Bros. & Co., and will include eight bathrooms complete in every detail. The brass goods will be attractively arranged in handsome showcases and the closets set up on raised circular platforms about the pillars supporting the upper floor. The room is now open to the inspection of visitors, and although the beauty of the woodwork may be appreciated, the full effect of the display when completed can only be guessed at. Additions are constantly being made, and the end will not be reached much before autumn, probably. The arrangement of the showroom is under the supervision of W. E. Hinsdale, who has made a reputation in this line of work The offices of Peck Bros. & Co. also have been remodeled and brought up to date in every feature. They are extremely handsome and convenient, and in many respects are models in their way.

A good use is made of *The Metal Worker* manual, "Practical Hints on Joint Wiping," in the Baron de Hirsch Trade Schools in New York City. Two copies of the work have been cut up and the two parts have been pasted on two large sheets. These, having been framed and glazed, are hung on the walls of the plumbing classroom for reference and perusal by the pupils. We are informed that this arrangement has been found very useful. Not only the text, but the illustrations, serve to impress the various points in connection with the joint wiping process on the minds of the learners. The pictures are found particularly valuable in this Jewish school, where many of the pupils have but a limited acquaintance with the English language.

James W. McCartney is opening a plumbing shop at Ellenville, N. Y.

Walter Calhoun, who has conducted a plumbing establishment at the corner of Market and Livingston streets, Amsterdam, N. Y., has purchased an interest of the business of Edward P.

Williams of 5 Spring street. The business will be continued under the firm name of Williams & Calhoun.

Levi Thurston, John Hale and Albert Hale have remodeled a store on Dock square, Rockport, Mass., and are about to start a plumbing and hardware business.

Hermenegilde Roy and Zenon St. Aubin have gone into partnership in the plumbing business in Montreal, Canada, under the firm name of Roy & St. Aubin.

Rock Island Heating & Plumbing Company were recently incorporated at Rock Island, Ill.; capital stock, $10,000; incorporators, Terry F. Burke, John Joers and Ernest Wagner.

Edward G. Allenbrand has bought the plumbing establishment of Alex. M. Mann on East Third street, Dunkirk, N. Y.

Solomon Gillespie is to occupy a new building that is being erected at Bound Brook, N. J., as a plumbing shop.

E. Armit has opened a plumber's shop in the north basement of the Miller & Huehn Block, at Hammond, Ind

Under date of March 14, notice is issued to the trade that the copartnership heretofore existing under the firm name of Curry & Hebblethwaite, Melrose, Mass., has been diasolved by the retirement of Joseph Hebblethwaite. Robert A. Curry will continue the business at the asme stand under his own name.

Secretary Ed. O'Donoghue informs *The Metal Worker* that the plumbers of Ogdensburg, N. Y., have organized and are enrolled as members of the New York State Association of Master Plumbers and have elected the following officers: President, P. H. Doyle; vice-president, Thomas H. Lavier; treasurer, Chas. Lavier; secretary, Ed. O'Donoghue; sergeant at-arms, O. W. Havens.

Kerregan & Ward is the name of a firm which have recently gone into business in Lewiston and Auburn, Maine.

R. & J. Robertson have opened on West street, Beverly Farms, Mass., a branch plumbing establishment.

Yarrington & McCabe, plumbers, have leased the store in Lewis' Block on Main street, Derby, Conn., and are fitting it up for use.

The Legislature of Ohio has under consideration a measure that is to require the examination and licensing of plumbers. The bill provides that in every town of 5000 or more inhabitants, and in every town having a system of water supply or sewerage, there shall be a board of examiners of plumbers of five members, three of whom shall be practical plumbers (one journeyman and two master), and of which the health officer and the inspector of buildings of the city shall be *ex-officio* members.

John Thompson and Wm. Allen have gone into the plumbing and tinsmith business at Washington, N. J.

The California State Labor Congress has adopted a platform, including "the collective ownership by the people of all means of production and distribution," and has agreed not to support any political party that does not agree with it.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

Caswell & Moore, Phœnixville, Pa., are engaged in roofing a house and several outbuildings belonging to Wm. Sounden, at Diamond Rock. They also have a contract for plumbing Moore Hall, the summer residence of Judge Pennypacker.

George E. Berehns of Ivoryton, Conn., has secured the contract for doing the plumbing work on N. G. Post's new building.

The sundry civil bill, now pending before Congress, includes an appropriation of $90,000 for remodeling the ventilation and plumbing systems in the Post Office building at Washington.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until April 11, for the steam heating and ventilating plant for the United States Court House and Post Office building at Danville, Ill. Drawings and specifications can be had from the Supervising Architect at Washington or from the superintendent, Danville, Ill.

The Hoffman-Russell Company, 82 Lake street, Chicago, are to furnish the steam heating plants for the flat building of H. F. Wachsmuth, 3811 Rose avenue, and for the flat building of C. Steinmetz, 38 Elmwood place.

Among the contracts recently taken for steam heating by Cook & Chick, 253-255 Kinzie street, Chicago, can be mentioned the following: Flat building of G. A. Webb, 1441 Monroe street; residence of Frank Grundies, Rockwell and Augusta streets, and the 18-flat building of M. M. Brown, Forty-eighth street and Calumet avenue.

The Wells & Newton Company, 274 Dearborn street, Chicago, are overhauling the plumbing in the Calumet Building, La Salle and Adams streets. The Cooper Nautilus closets will be used.

The Kewanee Boiler Company, 96 Lake street, Chicago, have just taken contracts for four 66 inches by 16 feet tubular boilers with fronts, smoke stacks and breechings, to be used on sections of the great Chicago drainage canal, the contracts for which were recently let. The company report that general business is improving, with indications of a good spring trade.

J. H. Moses, Croton Falls, N. Y., has purchased the tin and plumbing business lately carried on by A. B. Whitlock & Co. He recently visited New York, where he was the guest of George Butcher of Southard, Robertson & Co.

The City Council of Easton, Pa., passed an ordinance at a recent meeting granting to the Model Heating Company of Philadelphia the contract to erect a hot water heating plant in the Central station for $605; to erect a steam heating boiler with a Silaby automatic attachment at engine house No. 2, to the American Fire Eugine Company of Seneca Falls for $450; to the Easton Heating & Ventilating Company (Rohn & Ellicott) the contract to erect a hot water heating plant at engine house No. 3 for $412, and appropriating $1467 for the purposes named.

The Weymouth, Mass., authorities have appropriated $2500 for heating apparatus for the Hunt school.

J. R. Morris & Sons, Houston, Texas, have been awarded the contract for the plumbing and electric light wiring in a public building of that city, amounting to $4924.

James Cleland & Sons of Lynchburg, Va., have been awarded the contract for ventilating the new State Library building in Richmond, over bidders from New York, Philadelphia, Richmond and other big cities. T. B. Dornin & Son furnish the galvanized iron needed in fulfilling the contract. The amount received for the entire work will be nearly $10,000.

Bids will be received by the Board of Education of Detroit, Mich., up to April 3 for the heating and ventilating apparatus for three school houses to be erected in that city.

A. C. Hickey, 69 South Clinton street, Chicago, is doing the plumbing and gas fitting in the extension to the Hub Building, State and Jackson streets.

M. L. Mandable, 258 Clark street, Chicago, has the contract for the plumbing, sewerage and gas fitting in the flat building of P. Ryan, 491 North Clark street.

Lingenfelter & McClintock, Austin, Ill., have the contract for heating the flat building of Dr. Kearsley and Miss Isgrig, using the United States Heater Company's No. 306 Capitol hot water heater for the purpose.

The Kelly & Jones Company, 48-52 North Clinton street, Chicago, are to install a hot water heating plant in the residence of William H. Reed, Prairie avenue and Twentieth street.

NEW PUBLICATIONS.

American Plumbing. A complete compendium of practical plumbing from solder making to high class open work. By Alfred Revill. Size, 7½ x 5½ inches; 224 pages. Published by Excelsior Publishing House. Price, $2.

It is a well-known fact that the plumbing trade is more scantily supplied with literature than any other of the manual trades at the present day. The best books of the kind come from England, and as they treat of English practice they are of indifferent value in this country. It is, therefore, always welcome news to hear of the publication of a book relating to American practice. The present volume is not a particularly exhaustive treatise, but nevertheless it contains much information that will be useful to the young plumber who is anxious to advance himself in his chosen profession. Lead and Its Uses in Plumbing is noted in the beginning; then plumbers' tools are illustrated and described. Part V is given up to making joints and bends, the text being assisted by cuts. The next chapter, or part as it is called, is entitled Traps. Then come Soil Pipes, Sewer Connections, Vents, Water Closets, Sinks, Closet Cisterns, Bathtubs, Washtubs and Kitchen Boilers. A complete drainage job is described in Part XVI, which is followed by the plumbing regulations, taken from the publications of the Health Department of the City of New York. An alphabetical index at the end facilitates reference to the contents.

The United States Patent Office is now less in arrears with its work than has been the case for the past seven or eight years.

TIN PLATES.

Meurer Bros. Company's Tin Plate Works.

The new tin plate plant of Meurer Bros. Company, 575–577 Flushing avenue, Brooklyn, N. Y., to which allusion was made in these columns some weeks ago, is so far advanced that the first two tinning pots were put into operation on March 9. The initial product turned out—a roofing plate of Worcester grade—proved eminently satisfactory, and the works will run regularly from now on. The two machines already at work are of the Phillips pattern. Two others, of the Thomas & White pattern, will be installed in the course of a few days, and will be used for the production of bright plates. It is expected that at least six tinning machines will be in active operation day and night by the end of the present month, when the works will be fully equipped in all other respects. The full complement of tinning pots contemplated is ten, but the last four are not yet ready for installment. At present, while working one shift only, an output of 80 boxes of 20 x 28 roofing plates a day is made. This will be increased to 50 boxes per pot, as the men become more expert, and when they have the aid of the cleaning and dusting machinery now on its way. Eventually, it is hoped, with the aid of the full force of ten pots, to reach an output of 1000 boxes a day of 24 hours.

Messrs. Meurers' plant is excellently planned and equipped with the most modern and efficient labor saving devices. A steam pickling machine and steam squaring shears have been ordered, as well as a steam stamping machine for the manufacture of some of the tinned goods dealt in by the firm. Nothing but American black plates are used; and it is the intention of the firm to ultimately establish a rolling mill themselves for the production of this material. All the workmen are Americans, Messrs. Meurer being anxious to make the tin plates turned out by them unquestionable American products.

SCRAP.

According to a German official report from Bilbao, Spain, a tin plate works which was started in that city about seven years ago, and which for a long time had a hard fight for existence, is now in full swing. It is said to be seriously affecting the foreign trade with Spain in tin plates.

Although some of the largest tin plate works in Wales are entirely closed, and many of the smaller establishments are also idle, the output of tin plates is evidently in excess of the demand, while prices are unremunerative. The stock of plates in warehouses at Swansea, Wales, awaiting foreign shipment is about double the amount usually held at that port.

The Welsh tin plate makers have jointly taken up the 36-box question. At a meeting held recently a sub-committee was appointed to confer with the leaders of the workmen, with the object of increasing the make all round to 40 boxes per shift. Should this not be agreed to, it is intimated that a general reduction of wages will follow. Several more works have closed down on account of the adherence of the men to the 36-box rule.

British tin plate manufacturers are tiring of the delay and suspense in settling the tin plate tariff for the United States. The *Iron and Steel Trades Journal* of London believes that "if it were definitely announced that no reduction would be made in the duty on tin plates, the Welsh trade would at once revert to a state of comparative activity on account of American buying." There is no doubt that it is the uncertainty that is killing the trade at present.

Kahn Bros.' Tin Plate Works, at 525 East Nineteenth street, New York, were again put into operation on Thursday, March 22. The plant has been idle for a month owing to the inability of the firm to obtain enough American black plates, which they use exclusively. Messrs. Kahn are making roofing plates. Their brands are known as Mohawk, Juniata and First New York.

The Laufman Tin Plate Company, with works at Butler Junction, Freeport, Pa., send out circulars giving lists of the brands of plates they make, with tables of sizes, gauges, &c; also a few particulars regarding the quality of the plates. On the same sheet is printed a number of testimonial letters, recording the opinions of those who have used the plates. A second circular relates to Laufman's Apollo terne or leaded sheets, which are described as coated with a mixture of tin and desilverized lead, hand double dipped and oil finished, and are said to be adapted for car roofing, eave troughs, conductor pipes and cornice work.

From Gas City, Ind., comes the somewhat remarkable but, considering the times, very encouraging statement that skilled labor is scarce at the tin mills, the class of labor referred to being tin mill heaters. From the same source we learn that the Norwood tin plate plant is growing continually and the work of adding new mills is being pushed rapidly.

According to the statement of imports and exports of the United States for January, 1894, prepared by the Bureau of Statistics in Washington, the value of tin and terne plates and taggers' tin imported during the first seven months of the fiscal year 1893-94 was $6,874,896. The average of the five corresponding periods of seven months, from 1888-89, was $10,330,010, consequently the imports for 1893-94 as above exhibited show a falling off of $3,455,114 in value. As compared with those for the seven months ending January 31, 1893, the decrease this year was $2,286,594.

The Tariff bill, as amended by the majority of the Senate Finance Committee, has been finally laid before the Senate. Among the changes that have been made since it was reported from the House is the reduction of the duty on tin plates to 1 cent per pound instead of 1⅛ cents per pound as in the House bill. The reduction in the present reading of the bill is to take effect October 1, 1894.

"What is Tin Plate?" is the title of a dainty 16-page pamphlet issued by Hibbard, Spencer, Bartlett & Co. of Chicago. The publication, which is the work of H. B. Lyford, manager of the tin plate department, explains in very lucid style how tin plate is made, sets forth the differences in quality and on what such differences are based, and leads the reader up naturally to a contemplation of the merits of the H. S. B. Old Process and H. B. L Old Style ternes or roofing plates offered to the trade by Hibbard, Spencer, Bartlett & Co.

NEW PUBLICATIONS.

The Art of Coppersmithing. A Practical Treatise on Working Sheet Copper into all Forms. By John Fuller, Sr. Size, 10 x 6½ inches; 327 pages. Published by David Williams, 96-102 Reade street, New York. 1894. Price, $3.

Our readers will recognize from the above description a work prepared as a serial that appeared in *The Metal Worker*, the final chapters being published last year. The author is thoroughly conversant with his handicraft, as those who followed the series can testify. The work of coppersmithing, although filling so important a part among the trades, has never been described and this volume will be welcomed by the coppersmithing fraternity. The early part is the record of the apprenticeship of the author, and shows how he was advanced step by step from the simplest beginning to the more complicated operations. The body of the book, however, is given over to practical descriptions of the methods of making all sorts of articles from copper, and many of the articles described admit of slight variation to adapt them to any patterns that may be in fashion at different times or in different countries. A special feature of the work to which we would direct attention is the engravings, of which there are nearly 500, illustrating different devices, methods of working, patterns, various stages in the construction of the articles, tools, appliances, &c.; in fact, the whole subject is presented through these illustrations so comprehensively that the pictures would almost form an intelligible work by themselves. The book proper, that is, the text, is, however, in excellent keeping with the cuts. The style is simple, and what is all-important in a work of instruction, the author tells from his own experience in the plainest way, so that any apprentice or novice can follow out his instructions. It is not a book that was written by the author merely to sell, but it was worked out from the experience of one who had learned by hard labor every step in coppersmithing work, and who belongs to that body of conscientious writers who try to state things accurately.

THE RETAIL STORE.

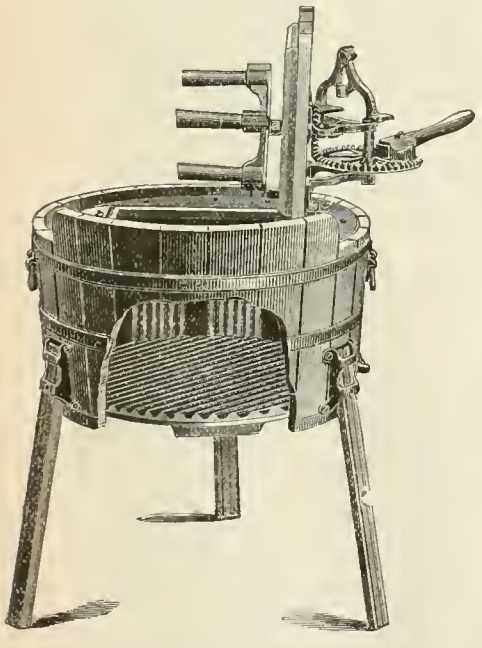
Marketing Goods Without Travelers.

From a well-known hardware house in the Southwest we have the following communication in which they refer to what they regard as one of the causes of irregularity in prices and other annoyances in connection with business: We have always contended that there is an overproduction of goods and that the drumming business is overdone, and is, to a great extent, the cause of demoralization and corrupt methods of doing bussness as practiced at the present time. We received to-day from a large manufacturer a circular which reads as follows: DEAR SIR: After carefully considering our mutual interests, we have decided to discontinue the expense of transacting our business through traveling solicitors, and give to our valued customers the advantage of the saving in expense by making a proportionate reduction in prices to our established trade. We recognize that the time has arrived when the most economical methods for conducting business must be adopted in order to furnish goods to dealers and consumers at the lowest possible price that will afford any margin of profit, and we feel confident that the trade will fully appreciate the advantages we are able to extend by dealing with them direct.

Our correspondents add that they predict this announcement to be the forerunner of many more.

The Bruner Washing Machine.

The accompanying cut represents a cedar washing machine put on the market by the Bruner Company,

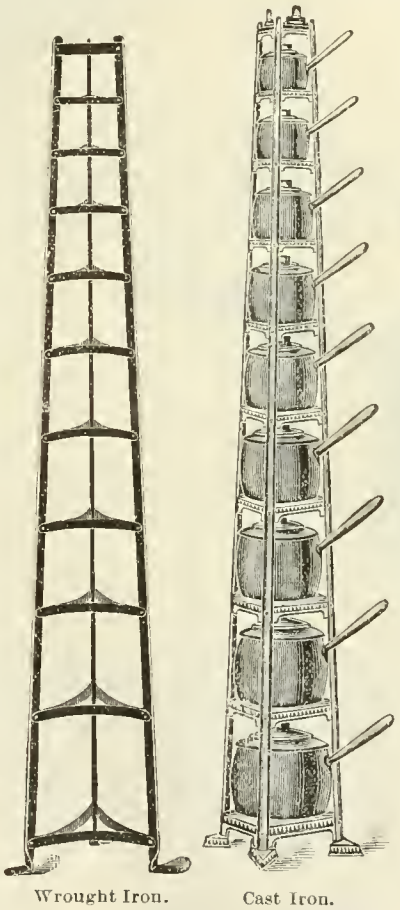


The Bruner Cedar Washing Machine.

Springfield, Ohio. The manufacturers state that the principle upon which the machine works is the expanding of the meshes of the goods washed, and that by the united action of condensed air, steam and suds the material is cleansed quicker than by other processes. The point is made that the corrugated bottom and corrugated breakers slush the water rapidly; and that after washing two hours in warm weather the hands cannot be held in the suds. The machine is made in styles A, B and C.

Saucepan Stands.

Silver & Co., 304-310 Hewes street, Brooklyn, and 20 Warren street, New York, are offering saucepan stands



Wrought Iron. Cast Iron.

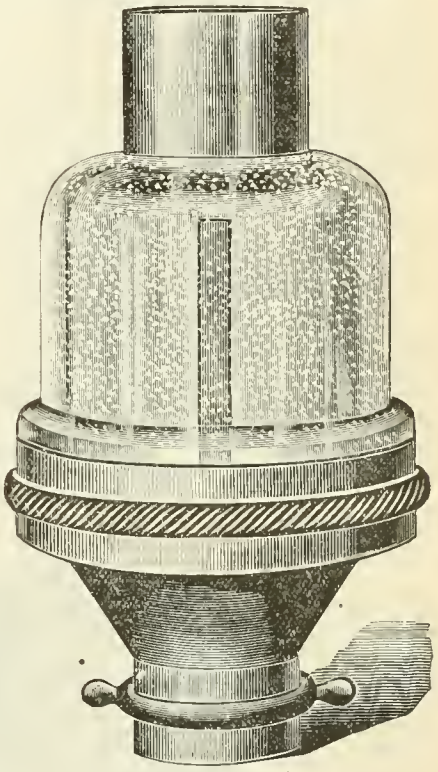
Saucepan Stands.

made of both wrought and cast iron, as illustrated herewith. They are referred to as strong, and handsomely japanned, and are designed for displaying saucepans as in Fig. 2; also deep and shallow pans and kettles. The point is made that the stands keep the utensils tidy and free from harm, and that an effective display is thus made of all sizes.

THE BUSINESS CARD of W. F. Adams, Toledo, Ohio, calls attention in a graphic way to the advantages of having stoves put up by an expert. It shows a worthy old couple struggling with an obstreperous stove pipe, which "Adams, the expert, could arrange for them in short order and thus save bad words, sleepless nights, family quarrels and perhaps a divorce suit."

The Clean Out Filter.

The Phillips Mfg. Company, 219 East Thirty fourth street, New York, are manufacturing the Clean Out filter, shown in the illustration. It con-



The Clean Out Filter.

sists of a cylinder of glass or nickel plated brass filled with fine quartz. The top section is made to fit either the New York or Pittsburgh standard hose bibb. The lower section has a rotating sleeve, to which are attached upright standards that reach nearly to the top of the cylinder, with a deflector plate at the top and having a strainer at the bottom. In use the water strikes the deflector and scatters instead of making a passage through the center. After the filter has been used for a time and become foul the rotating sleeve is operated, which thoroughly stirs the quartz; then by opening the faucet the quartz can be washed clean.

Embossed Mug.

The accompanying cut shows an embossed tin mug of handsome design,

Embossed Mug.

which Matthai, Ingram & Co. of Baltimore, Md., are putting on the market. It has a swell bottom, turned wire edge, square tin handle, and is very attractive in appearance. The mugs are sold at a low figure and are meeting with an excellent demand.

The Silver Cooking Crock.

The accompanying illustrations represent a cooking crock, offered by Silver & Co., 304-310 Hewes street, Brooklyn, and 20 Warren street, New York. As shown in Fig. 1, the crock

Fig. 1.—Cooking Crock.

is of porcelain, with a heavy tin cover, which when placed on the crock and given a turn will be securely locked in position, so that the crock may be carried by the cover handle. The crock is placed inside any covered vessel, such as an iron or tin saucepan or tin bucket, the outside vessel being partially filled with water and the crock containing the food to be cooked. Fig. 2 represents a vessel supplied by the company, or crocks may be purchased separately. The crock is designed for cooking cereal foods, milk, soups, vegetables, fruits, meats, &c. The manufacturers claim that with the use of the crock stirring is unnecessary, burning impossible, and that the crock preserves the nutritious juices and delicate flavors, making the food appetizing and satisfying. The crocks are made in 1, 2, 3 and 4 quart sizes.

Fig. 2.—Cooking Crock in Use.

Perfection Hammock Rope Adjuster.

Covert's Saddlery Works, Farmer, N. Y., are offering a hammock rope adjuster, as shown in Fig. 1. It consists of links, two of which are open, through which the hammock rope is passed, as in Fig. 2. The manufacturers claim that the device is safe and quickly adjusted, and that the construction is so simple that a child can operate it as well as a grown person.

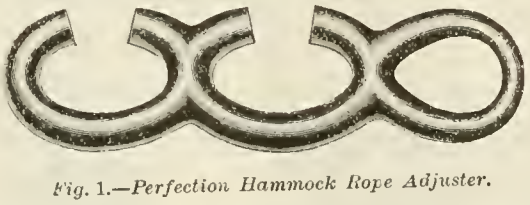


Fig. 1.—Perfection Hammock Rope Adjuster.

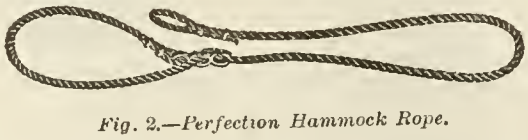

Fig. 2.—Perfection Hammock Rope.

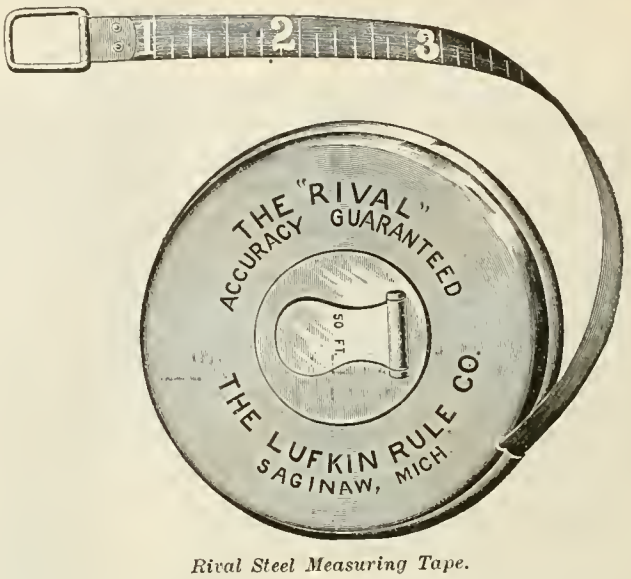
Rival Steel Measuring Tape.

The Lufkin Rule Company, Saginaw, Mich., are offering the steel measuring tape illustrated herewith. The tape is marked only on one side in feet, inches and eighths. The case is deacribed as being brass, nicely nickel plated and as compact and durable. The winding drum is of somewhat larger diameter than the company's Reliable tape, which gives a good long crank and winds easily, notwithstanding it has not the advantage of an extension handle, but the handle folds nearly flush with the case. The tape is put on the market to meet the demand from contractors, builders, masons and others who appreciate the value of a steel measuring tape and who do not feel inclined to invest in the higher priced article. The manufacturers state that while the tape is sold at a comparatively low price yet none of its practical features have been in any way sacrificed and that it is a first-class article, and is fully guaranteed by them.



Rival Steel Measuring Tape.

Billing Gasoline Stoves.

From F. B. K., *Delaware, Ohio.*—I would like to ask retail dealers handling gasoline stoves if the manufacturers all over the country are doing with them as they are with me, or rather as they are trying to do, as I have so far refused their requests. I order gasoline stoves without ovens and they make out the bill as follows:

A No. 22 stove	$20.00
Less 30 per cent	6.00
Total	$14.00
Deduction for oven	2.00
Total	$12.00

making the stove cost $12, where it ought to be $11.20. Then if you buy ovens, they are listed $4, less 30 per cent., making them cost $2.80. I do not understand what the manufacturers mean by such business. We can buy ovens of outside parties and if the manufacturers cannot sell ovens as cheaply as the outsiders they should confine their sales to stoves. They have no right to compel a man to buy what he does not want, nor have they any right to ask a man to pay for what he does not get. If the manufacturers' association is organized for such a purpose, the sooner it disbands the better, in my judgment, it will be. I am told that the above is the rule. If the retail dealers allow such a thing with gasoline stove manufacturers, how will it be with the manufacturers of other stoves? They might say, if you buy a cook stove of us you must buy the pipe and trimmings. If you don't, we will charge the profit on the pipe and trimmings any way, so we don't care whether you buy them or not.

E. M. ALLEN, 114 Franklin street, New York, is introducing among dealers in House Furnishing Goods Aluminum Cooking Utensils and other vessels made by the Illinois Pure Aluminum Company, Lemont, Ill. This material, which is continually being utilized for numberless purposes, is referred to in connection with culinary articles as free from poisons, unaffected by medicinal acids, durable, clean, light, and not liable to tarnish.

Architects and others who keep in advance of the times insist, says the Philadelphia *Record*, that stone will be more extensively used next season than ever before for residences, the craze for mottled and colored bricks being on the wane.

STOVE TRADE NOTES.

Cupola Management.*—VIII.

BY DR. EDWARD KIRK.

Poking the Tuyeres.

When the blast is first put on the fuel in front of each tuyere is bright and hot, but it is soon chilled and blackened by the large volume of cold blast passing in, and the tuyere presents the appearance of being closed up and admitting no air to the cupola. The blast when first put on does not remove the fuel and make a less opening in front of each tuyere to get into the cupola, but works its way between the pieces of fuel in front of the tuyeres, and these openings remain open for the passage of blast after the fuel becomes cold and black. The blast, therefore, passes into the cupola just the same as when the fuel was hot, and it is not necessary to poke the tuyere with a bar or break away the cold fuel in front of each tuyere to let the blast into the cupola.

Toward the end of a long heat slag and cinder settle and chill at the bottom of a cupola, and often not only close the blast off at the tuyeres but prevent it passing freely through the stock and out at the top. If the tuyeres are poked at this stage of the heat an opening may be made well into the stock. But in working the bar around in forming this opening most of the natural passages the blast has made for entering the stock are closed up. The new opening is only a hole bored into a tough slag or cinder from which there is no way for the blast to escape into the stock, and less blast enters a cupola after the tuyeres have been poked and opened up than entered before. The only time a tuyere should be poked with a bar is when cinder or slag has lodged or formed in front of it in such a way as to run a stream of molten iron into the tuyere. The tuyere door should then be opened and the slag or cinder broken away with a bar to prevent the iron running into the tuyere.

Fuel.

Ten pounds of iron are melted with 1 pound of anthracite coal and 15 pounds of iron are melted with a pound of Connellsville coke. But this melting is done in the foundry office or in the mind of the foreman, and it takes a little more fuel to melt iron in a cupola for foundry work. Six pounds of iron to 1 of anthracite coal and 8 pounds of iron to 1 of Connellsville coke is considered good melting by practical foundrymen. A little better than this can be done in a full heat for the size of the cupola and under favorable circumstances, but in the majority of foundries less pounds of iron are melted to 1 of fuel than the above amount.

It is sometimes necessary for the melter to put in a few extra shovels of fuel when the bed has been burned too much before charging, or to level up the charges when two or three men are shoveling in fuel at the same time and get it uneven. The melter is generally blamed if the iron comes dull from any cause, and he will generally put in a few extra shovels of fuel the next heat to make it hot, and if the iron does come hot the next heat the extra shovels are put in every heat, but are not put on the cupola report. In this way foundrymen are often misled by the cupola report and suppose they are melting more pounds of iron to the pound of fuel than they really are. The only way the foundryman can know exactly how many pounds of iron he is melting to the pound of fuel is to have an accurate account kept of the amount of iron melted and compare it with the amount of fuel bought and delivered for the cupola, after deducting from it any amount that may have been consumed in stoves or coke ovens.

I recently met a foundryman who thought he was melting 14 pounds of iron to the pound of fuel, but when he came to compare the iron melted with the fuel bought and delivered for the cupola he found he was only melting about 7 pounds of iron to the pound of fuel, and about the same results would be found in every foundry that is melting a very large per cent. of iron to fuel. There is nothing gained by saving a few cents' worth of fuel in the cupola and losing a dollar's worth of work on the floor by dull iron, and there is nothing gained by using too great a quantity of fuel, for too much fuel in a cupola makes dull iron as well as too little fuel.

Iron is not melted in a cupola for the fun of melting it or to learn how many pounds of iron can be melted with a pound of fuel, but is melted to make castings. What the foundryman wants from the cupola at the tap hole is an iron hot and fluid enough to make a sound casting regardless of the amount of fuel required to produce it. As before stated, iron cannot be melted hot and fast in a cupola with either too much or too little fuel, and foundrymen have only to melt their iron as hot and fast as iron can be melted in a cupola of the size they are using, to know that they are not using either too much or too little fuel in melting.

If the foundryman will ask his neighbor what is the size of his cupola, how many tons does he melt per hour, how long does it take him to run off a heat, he will get a better guide to run his cupola by than if he asks him how many pounds of iron he melts to the pound of fuel As soon as the founder undertakes to imitate his neighbor and do faster melting or get better results from his cupola, he will hear the old, old story from both melter and foreman: "We haven't enough blast." More cupolas have too much blast than too little, and the apparent deficiency of blast is due in the majority of cases to too much fuel in the cupola and the iron being melted only on the upper edge of the melting zone. It does not make any difference how much or how little blast a cupola has. If it is given an even volume of blast throughout the heat, the cupola will melt a stream of iron of an even size and temperature throughout the heat except toward the end of a long heat, when the stream may get smaller. If the melter cannot run this kind of a stream from his cupola with an even blast, then he is at fault, and neither the blast, nor too much fuel is the cause of the uneven melting.

I have watched the charging of cupolas in a great many stove and machinery foundries, and as a rule more fuel is consumed in making dull iron in a machine foundry than is consumed to make a hot iron in a stove foundry. This is simply because hot even iron cannot be produced with bad working of a cupola and too great a quantity of fuel, and the stove founder must have his cupola properly worked or he cannot use the iron to pour the work.

Tapping Bars.

The tapping bars are made of round iron of from ½ to 1 inch diameter and are from 3 to 10 feet long. The hand bars are made with an oval ring at one end to serve as a handle for rotating and withdrawing the bar when tapping. The other end is drawn down to a long sharp point for cutting away the bod and making the tap hole. The bars for sledging are made straight with a long sharp point at one end. This bar is only used in case the tap hole becomes so tightly closed it cannot be opened with the hand bar, and seldom more than one is provided for a cupola. From three to six hand bars are provided for each cupola, and when the ladles are all of the same size the tap bars are all made of the same size, except one or two small ones which are provided for clearing the hole of any slag or dirt that may be carried into it by the iron.

When the iron is melted for different sized work and large and small ladles are used, the bars are made of different sizes, so a large or small hole may be made to suit the tap to be made or ladle to be filled. The bars are all made straight except when the tapping is done from the side of a long spout. They are then slightly curved near the point, so the hole can be made in a line with the spout. The bars are dressed and pointed at the forge before each heat, and are given any shape of point the melter may fancy. A square point cuts away a bod very rapidly when rotated and leaves a nice, clean hole, but it is very difficult to keep a point square, for they generally become round after a few taps have been made and they come in contact with the molten iron a few times. For this reason they are generally made round at the forge.

Some melters have a short steel bar, with a sharp flat point, which they use for cutting away the bod before tapping, but never use it for opening the hole. This they do to remove the greater part of the bod from the spout before tapping, and prevent it getting into the ladles. A hammer and an anvil, or an iron block, should be placed near the cupola for straightening the points and breaking cinder or dross from the bars, and a rack should be provided within easy reach of the tap hole, in which to place the tap bars on end until wanted for use. There is nothing more slovenly and dangerous about a foundry than to have the tap bars lying around the floor when a heat is being run, and

*Copyrighted, 1894, by Dr. Edward Kirk.

it is just as bad to set them up against a post from which they are all the time falling down.

The Gasoline Stove Trade.

A correspondent writing from the West calls attention to certain practices in the gasoline stove trade that deserve the serious attention of the retailers. His letter is as follows:

Two questions are now agitating the manufacturers of gasoline stoves. The first is the smallness of the orders being received by them, and the other is the cancellation of orders for stoves already placed. Treating the first complaint from the manufacturers' standpoint, we find that many concerns who have heretofore ordered in large quantities, some even being carload buyers, are now taking one-half to one-third of the amount ordered last year, yet the difference in the total number sold by retailers this year is not likely to be very much, not more than say 10 per cent. Dealers, however, are sending in orders that are 25, 50 and even 60 per cent. less than last year. When the active demand sets in the retailer will find himself short of stock, and will send in his order requesting immediate shipment. Right here is the important point. He cannot secure immediate shipment, as gasoline stoves are not made in a day, and should the demand prove greater than last year there will be a great many disappointed retailers throughout the country. Gasoline stoves have now reached a point of practical perfection so that they can be carried over from one year to another without losing their value, and it is only justice that the dealer should bear his share of the burden.

Cancellation of orders is the second complaint made by manufacturers and is one of the most aggravating annoyances with which they have to contend. As early as October, or immediately after the use of gasoline stoves is discontinued for the season, the manufacturers send out their traveling men, who book orders for delivery say six to eight months ahead. After the first of the year the manufacturer looks over his order book and calculates how many stoves will be required to fill his customers' wants. On the basis of the orders thus received he places his orders for material to be used in the manufacture of his stoves, such as tin plate, sheet iron, brass, bar iron, screws, rivets and other materials too numerous to mention. After making all the necessary arrangements for turning out so many stoves, cancellations begin to arrive and continue throughout the season. It would be far better not to order a stove rather than order 100 and then cancel 75 of them, which is very often done. Dealers evidently do not stop to think of the vast amount of trouble and expense to which they put the manufacturers, else many of them would cancel fewer orders than they now do. The manufacturers keep a record of those who make a habit of canceling orders, and as gasoline stoves are now sold by nearly all manufacturers to only one dealer in each town, whenever an opportunity presents itself these dealers are dropped and other agents appointed. Thus the dealer not only injures the manufacturers' but his own business at the same time. This is a question on which it would be well for the dealers of the country to ponder, and the more they study it the more pronounced becomes the justice of the manufacturers' complaints as outlined above.

ODD PLATES.

The Lehigh Stove & Mfg. Company of Lehighton, Pa., send us circulars of the Gem-Lehigh five hole range, made in three sizes, and also of the Lehigh, another five-hole range offered in three sizes. The former construction is fitted with anti-clinker grate, top end shelf, broiling door, illuminated wood door and nickel trimmings. Accompanying the circulars is a folder entitled "Lo, the Poor Indian." On opening it we find the following, in which our readers may be interested, outside of its reference to Lehigh stoves: "Hasn't been so very long since the wild Indian roamed our valley, and as he shot his canoe under the shadows of our mountains he called the stream 'Lehigh' — black water. How little he knew the future of that name in the coming century! The age of steam and of iron, of education and of luxury was coming, and the steam was to be made from Lehigh coal; the railroads and locomotives and factory wheels were to be made of Lehigh iron; a million boys of the nineteenth century were to do their sums on Lehigh slates; and in 10,000 happy homes the twilight shadows would find the family gathered around a Lehigh stove. Alas, poor Indian! How little he knew!"

The Mobile Stove and Novelty Works of Mobile, Ala., have been organized. E. E. Posey, G. Heidel and Jas. K. Glennon are the incorporators.

The annual meeting of the stockholders of the March-Brownback Stove Company, whose extensive works are at Pottstown, Pa., was held at that place last week, under the chairmanship of A. G. Saylor. The following officers were elected: President, James Brownback; vice-president, James Rogers; treasurer, T. J. March; secretary, H. M. Ebert; directors, James Brownback, Franklin March, T. J. March, James Rogers, John H. Towers, A. K. Shaner, Henry G. Kulp.

Duparquet, Huot & Moneuse, 43–45 Wooster street, New York, manufacturers and dealers in fine hotel and kitchen supplies, are now installing the cooking ranges and similar appliances in the rooms of the Hardware Club in the new Postal Telegraph Building, Broadway and Murray streets. They expect to have their part of the kitchen battery finished by April 1.

The foundry of the Bussey & McLeod Stove Company, Troy, N. Y., which has been shut down for several months, resumed operations last week with a full force of 250 men.

The first cast for some time was made during the past week in the foundry of Burdett, Smith & Co., at Troy, N. Y.

L. G. Comparet of 314 Walnut street, Des Moines, Iowa, is offering the trade a full line of steel ranges adapted for family use. The bodies of the stoves are made of heavy steel, well lined with asbestos, while the tops and all castings are of the best grade of iron. Other features include sectional fire back, large ash pan, dumping and shaking grate, side hopper feed and capacious oven. The claim is made that the flues are so constructed as to regulate the heat of the oven to any degree desired. The range is known under the name Alta, and is referred to as being especially adapted to the use of Western fuels. It is made in two sizes, one having four boiler holes and the other six. Mr. Comparet also makes the Pioneer range in six different sizes, adapted for large families and hotel use.

The differences existing between the Schuylkill Valley Stove Company of Spring City, Pa., and their employees, by which the works were closed for a time, have been amicably adjusted and the plant started up during the past week.

A. Weiskittel & Son of Baltimore, Md., have issued a very neat catalogue of over 50 pages, relating to the Fire King gas stoves and ranges. The opening pages are devoted to testimonials, following which the goods named are illustrated and described in such a way as to emphasize the special features. In addition to the various kinds of Fire King gas stoves to which attention is invited may be mentioned ovens, sadiron heaters, tailors' iron heaters, baking plates, &c. Some remarks are given as to the reasons why gas should be used as a fuel, while a telegraphic code and comprehensive index constitute interesting features. The volume is neatly bound in colored paper covers, with side title embossed in two colors upon a black ground.

The grievance of the mounters employed by the Reading Stove Works, Reading, Pa., appears to have grown out of the price fixed upon for mounting a new range recently put in the sand. We understand that the company offered a piece price for mounting the range which is claimed to be higher than the price paid for mounting any other range of its class in Eastern Pennsylvania. The offer was considered liberal and that the men would be able to earn good wages at the figure. The mounters, however, differed in their view of the matter and went out on strike, which compelled the company to close their mounting department. It is expected, however, that the differences will soon be adjusted.

The Barstow Stove Company of Providence, R. I., are distributing colored circulars calling attention to the Bay State goods which they manufacture. A representation is given at the left of a train of cars, while at the right is a large black star. The statement is made that the "Bay State express is the best train to take between our Boston, Providence and New York houses, and we are daily shipping Bay State ranges and stoves over the same rails. The equipment of the Bay State express train is perfect. It runs smoothly and makes fast time. So is the workmanship of the Bay State goods perfect—they sell easily and rapidly. If you want to know more about it light a piece of cotton twine and apply a spark to the smoke stack of the locomotive and also to the star. The smoke will tell the story." Following the suggestion and applying the spark to the paper results in the burning in it of the words "Bay State Line."

It is stated that the Florence Stove Works of Florence, Ala., which have been idle for some time past, have been purchased by parties who will convert them into a plant for the manufacture and repair of machinery.

The Standard Lighting Company of Cleveland, Ohio, report their sales of New Process vapor stoves up to the present time as a trifle more than 50 per cent. in excess of the sales for the corresponding period of last year. They attribute this increase to the growing popularity of the evaporating stove, which has been much improved for the

season of 1894. The company also report collections good and the outlook healthy.

THE ANNUAL STATEMENT of the Employees Mutual Benefit Association, the members of which are employees of the Michigan Stove Company, show the receipts for the year ending February 24, 1894, to have been $3242.13 and the disbursements in the way of benefits and expenses $1231.98, leaving cash on hand $2010.15. The association has been in existence since May 12, 1882, during which time the sum of $16,911.85 has been disbursed in the way of benefits. The association is supported entirely by a system of dues contributed by the members.

AT THE ANNUAL MEETING of the stockholders of the Fuller-Warren Company, Milwaukee, Wis., held early in the month, reports were presented showing a very satisfactory business during the past year. The election of directors resulted in the selection of Walter P. Warren, Troy, N. Y.; William Plankington, Francis Hinton, H. S. Haselton, George L. Graves, John E. Hansen and H. A. Viets, of Milwaukee, and G. Wolfe, of Troy. We understand that John Johnson was placed in the directory to succeed G. S. Mitchell, who was temporarily elected last summer to succeed A. W. Rich, retired. At a meeting of the directors Walter P. Warren of Troy was elected president; H. A. Viets of Milwaukee vice-president and manager, and C. W. Jones of Milwaukee secretary.

SOUTHARD, ROBERTSON & Co., Water street and Peck slip, New York, favor us with a four page circular of the Waldorf range, made portable or brick set. This is a new construction, heavy and durable, with large ventilated oven, patent adjustable extension flue strip for regulating the heat and draft in the bottom of the oven; extra heavy covers, one of which is composed of a series of nested rings opening to 3½ inches; patent oscillating or flat bottom grate, capacious ash pan, patent oven door opener and Read's patent damper. The range is made with 6-inch smoke pipe in the center, thus rendering flue connection easy. The Waldorf is offered with a skeleton closet, or full warming closet and sifting grate complete, as may be desired.

THE GLAZIER OIL STOVE COMPANY of Chelsea, Mich., are erecting an addition to their power house 15 x 54 feet in size. It is of brick and one story in hight. The front on Main street will for the present be used as an office and the rear for a storeroom.

THE EXTENSIVE stove works of Rathbone, Sard & Co., at Albany, N. Y., have resumed operations and are now running with a full force of men. The goods sold in the Eastern and Middle States are turned out at the Albany plant, while those sold in the West are manufactured at Aurora, Ill The company refer to the extent of their Albany plant, which, before the establishment of the works at Aurora, comprised five cupolas, and now still turns out a very large stove product.

THE BRIDGE & BEACH MFG. COMPANY of St. Louis, Mo., are increasing their manufacturing facilities by the erection of a seven story building 50 x 225 feet in size, which will be used for storage and mounting purposes and fitted with all necessary modern machinery and appliances. The company are also adding a new molding room and rearranging the rest of their plant in such a way as to give them a stove foundry which will rank among the most complete and best arranged in the country. They expect to have the improvements completed and the entire plant in full operation by June 1, when they will be prepared to keep pace with the large and growing demand for Superior stoves and ranges. Several new patterns of cook stoves, ranges and heaters are in preparation and the goods will be brought out as rapidly as possible. The company state that they have accumulated a large and well assorted stock and are in a position to promptly fill all orders with which they may be intrusted.

F. MEYER & BRO. COMPANY, with office at 1313 South Adams street and works at 1300-1304 South Washington street, Peoria, Ill., have just completed extensive alterations by which their manufacturing capacity is largely increased. About a year ago the company purchased outright the patent covering the Weir gas and soot consuming furnace, and the demand for it has increased to such an extent that the improvements noted were found necessary. The statement is made that this furnace consumes soot and gases, is gas tight and does not admit any smoke into the house. The heater is made of steel. Frank Meyer, the originator of the enterprise, has been in business for over 27 years, the firm being known for a time under the name of Meyer Bros., and about two years ago the present company was incorporated.

SPICER STOVE COMPANY, Providence, R. I., are making additions and changes to their foundry in the way of increasing their manufacturing facilities. These changes are mostly in the line of rearrangement of old buildings and apartments and will add greatly to the convenience of the plant as well as to its size.

THE QUICK MEAL STOVE COMPANY, St. Louis, Mo., advise us that the total number of stoves sold by them this year up to and including the 19th inst. is just 4 per cent. less than for the same period of last year. This is a very creditable showing, and especially so when it is remembered that the first quarter of 1893 was the heaviest in the history of their business. They have just ordered the second edition of their gasoline stove pamphlet, consisting of 200,000 copies. The first edition was 750,000, so that the total edition will not fall much short of 1,000,000 copies.

THE regular monthly meeting of the Western Foundrymen's Association will occur on Wednesday, March 28, at 7.30 p.m., in rooms 702-703 Temple Court Building, corner of Dearborn and Quincy streets, Chicago, Ill. By request of the association W. J. Keep will present a short and very interesting paper on "Cupola Melting and Strength of Cast Iron."

SAM S. UTTER of 113 Beekman street, New York City, has been taking advantage of the fine spring weather in having his four story warehouse thoroughly renovated, and at present a large number of plasterers, carpenters and painters are busily engaged in the work. After the improvements have been completed a flagstaff 20 feet in hight will replace the old one and will be surmounted by a weather vane carrying a gold-plated rooster 4 feet tall. We understand that this weather vane will be so arranged that every day at exactly 12 o'clock the rooster will crow, the mechanism being operated by steam. Mr. Utter's counting room will be finished in a very tasteful and attractive manner, and the floor covered with Turkish rugs of rich design. Opening from the main office is to be a room for customers, provided with desks and stationery for letter writing. It is also intended that this room shall be used as headquarters for customers while in the city. Mr. Utter reports a good demand for his line of gas and oil stoves, and states that during the past week he shipped over 20 carloads to agents throughout the country.

J. B. COPP has tendered his resignation as manager of the Chicago branch of the Peninsular Stove Company of Detroit, Mich., to take effect April 1 of the present year.

News and Notes.

A recent order of the Treasury Department, permitting the unloading of vessels before entry, is much appreciated by importers, as saving a delay which is frequently costly and inconvenient.

A bill to extend the limits of the port of New York so as to include Yonkers, Westchester County, has been favorably reported by the House Committee on Commerce.

By the deepening and widening of the Eel River for a distance of 20 miles, several thousands of acres of low swamp lands in Indiana, now worthless, are to be reclaimed.

Eastern business from Cincinnati is to be pooled between the Pennsylvania, Baltimore & Ohio, Southwestern and "Big Four" railroads.

A Scandinavian Industrial Exhibition will be held at Malmö, Sweden, in 1896.

Two hundred tons of Harveyized steel armor plates for the U. S. monitor "Puritan" were shipped on Friday from the Bethlehem Iron Works.

Shipments of gold from South Africa in 1893 reached the value of $26,400,000.

The total war ship tonnage launched by the most active naval powers in 1893 was: France, 52,188; United States, 40,050; Great Britain, 28,920; and Russia, 17,320.

News comes from Australia of the discovery of some extremely rich gold fields in the colony of Victoria, near the old mining camp of Ballarat.

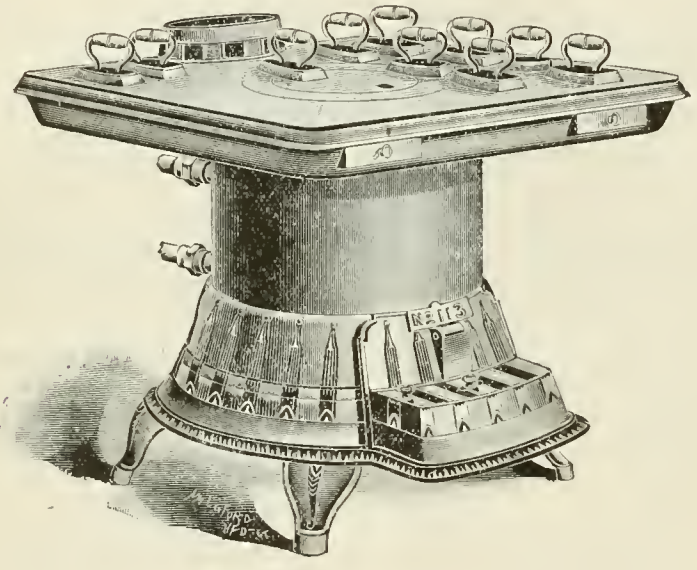
The New York factory inspectors find that during the year 1893 the proportion of child labor in this State has decreased from 38 per 1000 to 34 per 1000 of operators.

The project for a ship canal from Lake Superior to the Mississippi is receiving enthusiastic support in the Northwestern States. The scheme would, it is believed, prove a great benefit to the whole business of the West. Government engineers pronounce the plan perfectly practicable, and an appropriation of $10,000 will be asked for to determine the most feasible route.

The annual trade returns of the Dominion of Canada for 1893, just issued, show a volume of foreign trade $6,270,000 in excess of that of 1892, which was then the highest on record. The value of the imports into Canada last year was $129,074,268, and that of exports $118,564,352. The trade with the United States in 1893 amounted to $108,984,978 in value, as compared with $102,957,064 in the year 1892.

Richmond Laundry Range.

The illustration herewith shows a new laundry range, the Richmond, just being brought out by Higgins & Co., 379 Lexington avenue, New York. It is made in one size with a substantial base which contains an easy working grate and supports the upper parts. The fire chamber is furnished in three styles, tile lined, or one-third of it a water heater, or the whole as an annular water chamber, giving it a water heating capacity of from 60 to 150 gallons. The top rests on the fire chamber and has a capacity for heating 25 or 30 sad irons. It is arranged with a flue providing for the heating of all parts and has a check damper for controlling the draft. A large ring and cover are placed over the fire so that a kettle can be used if de sired. It is adapted for use in hotels, institutions and families where a large



Richmond Laundry Range.

quantity of hot water and a large number of hot irons are needed.

The Rusting of Iron and Steel.

The phenomena of chemical combination appear to be exceedingly complex. Not so very many years ago we were taught that a mixture of oxygen and hydrogen would combine to form water when an electric spark was passed through them. The matter appeared simple, was easily expressed in chemical formulæ, and illustrated by experiment. Now we have learned that it is impossible to make such a mixture explode when it consists of perfectly pure and dry gases. When, however, the slightest trace of moisture is present, the combination takes place at once, thus illustrating the importance of those "next-to-nothings" which were so ably and so pleasantly discussed by Sir Frederick Bramwell in his address to the British Association. The oxidation of iron, though a more familiar phenomenon, is at least as complex as that of hydrogen. In spite of the proverb, this familiarity has been very far from breeding contempt, as its commercial importance has attracted very considerable attention to the subject, and though there is still much to be learned, some few facts appear to be now established. In the first place, neither bright iron nor steel will rust in pure water or in pure air. The presence of carbonic acid, or some similar agent, seems necessary, although the final product may be destitute of carbon. Even when oxygen, moisture, and carbonic acid are all present, rusting will not, it appears, take place unless the moisture condenses on the surface of the metal. When rusting does take place under ordinary circumstances, the first atage appears to be the formation of ferrous carbonate. This carbonate is then dissolved in carbonic acid water to form ferrous bicarbonate, which latter is then decomposed in presence of air and moisture to form hydrated ferric oxide, magnetic oxide being formed as an intermediate product. This fact as to the formation of the magnetic oxide is curious, as the Bower-Barff process of protecting iron and steel consists in coating the metal with a firmly adherent layer of this very oxide.

Every one knows that when a bar of iron has commenced to rust the corrosion proceeds apace. A polished bar will resist oxidation for a comparatively long time, even under somewhat unfavorable conditions, but once the rust has commenced to form it does not take long for it to cover the whole of the bar. One reason for this may be the fact that the rust is electro-positive to the iron, but it is also partly attributable to the final product, the hydrated ferric oxide being only formed at the end of several intermediate stages of the oxidation, and to its hygroscopic properties, which favor the absorption of moisture from the air. In certain situations, other acids besides carbonic may take part in the corrosion of iron. The metal work in bridges over railways is particularly exposed to fumes, and some engineers consider that in such cases no plates less than ⅝ inch thick should be made use of, even in the case of the flooring.

The whole question of the rusting of iron and steel work has been discussed in considerable detail by Thomas Turner in a paper recently read before the South Staffordshire Institute of Iron and Steel Works Managers. It is now pretty generally acknowledged that, so far as ordinary exposure to the weather is concerned, iron is less liable to rust than steel. Unfortunately, however, this capacity for resisting rust seems to be greater in the common irons than in the best qualities, and has been attributed to the phosphorus contained in the former, which seems to have a protective action. When iron and steel are used in conjunction, there is no certainty which will be the more liable to rust. The potential difference of contact between the two is very small, and though in general wrought iron is found to be electro-positive to steel, there seem reasons for believing that this may not be so in all conditions.

W. Denny has instanced a case in which the steel shell plates of a vessel remained clean, while the iron stem plate and rudder forgings were much corroded. The ballast tanks of ships are particularly exposed to rust. Bilge water is an exceptionally powerful corroding agent and several engineers have suggested the use of iron plating in ships in those parts exposed to bilge water, even when the body of the ship is of steel. In steam boilers it is claimed that there is little difference in the behavior of the two metals, and certainly steel boilers, when properly looked after, have been proved to have a long life. Plates thoroughly cleaned from scale are less liable to corrosion than when used just as they come from the rolls, and the Admiralty have accordingly adopted the practice of pickling the plates before being used. In a case of pitting, Mr. John found a particle of black oxide at the bottom of each pit. Experiment shows that this black oxide is strongly electro-positive to the plates.

Cast iron seems in general to last better in sea water than either wrought iron or steel. Trautwine, however, relates that the cast iron cannons of the "Royal George" and the "Royal Edgar," after an immersion of 62 aud 133 years respectively, had become quite soft, and were in some cases like plumbago. A very similar experience was noted with the cast iron aluice gates of the Caledonian Canal. Much apparently depends on the quality of the iron. Trautwine recommends white, close-grained cast iron, while Mr. Turner quotes from a British Association report recommending gray iron.

The alloys of iron with nickel, cobalt and chromium appear less liable to rust than ordinary iron, while the presence of manganese appears to render the iron more sensitive to attack by corrosion.

Herr Lentz, in a paper read before the German Society of Engineers, makes the statement that there are 109,000 locomotives now in use in the world. He credits 63,000 to Europe, 40,000 to America, 3300 to Asia, 2000 to Australia and 700 to Africa. Of those used in Europe Great Britain owns 17,000 Germany 15,000 and France 11,000.

The total number of immigrants arriving at New York, Philadelphia, Baltimore and Boston during 1893 was 431,712. These comprise four-fifths of all the arrivals at American ports.

British Board of Trade returns for the month of February show an improvement in both imports and exports as compared with the corresponding month last year. The exports increased $2,832,000 and the imports $20,256,000.

The gratifying fact is noted by Dun's agency that the amount of failures in the United States during February was only $15,000,000, as against $30,946,000 in January, a decrease of more than 50 per cent.

TRADE REPORT.

The Iron Market.

The condition of the market has not improved within the past few days. Pig Metal is comparatively steady, but Billets and Finished Material are weak and depressed and hardly quotable on large lots. To make mattera still worse, the railroads are said to be cutting East-bound freights, with an intimation that the rate war has hardly commenced. It is claimed that $1.70 is accepted against a nominal rate of $2 30, and that before the end of the week business will be done at lesa than $1.70. The volume of business is not increasing to any appreciable extent, and although the demand is of a more general character, it is difficult for the mills to hold their own compared with the earlier months of the year. The reduced rates from the West will make the situation still more onerous, as it gives an additional advantage to mills in that section of at least 50¢ @ $1 ℔ ton. The only hope that the trade seem to have is that something unexpected will happen and thereby give things a turn which seems almost hopeless under present conditions.

Pig Iron.—While some of the furnace agents in New York report quite a fair volume of business, others find sales very slow. The lowering in rates of freight from the Mahoning Valley, amounting to 50¢ ℔ ton, places American Scotch from that section at closer prices here, say, $13 75 @ $14 for No. 1, and $12.75 @ $13 for No. 2. We quote standard brands $13 @ $13 50 for No. 1; $12 @ $12.50 for No. 2, at tidewater. Southern Iron, same delivery, $12.75 @ $13.25 for No. 1; $11.25 @ $11.75 for No. 2; $11 @ $11.25 for No. 3; $11.25 @ $11.75 for No. 2 Soft, and $11.75 @ $12 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10.50 @ $11.

Philadelphia advices state that the Pig Iron market in that territory is not materially different to what it has been for several weeks past, although the general movement may be a trifle larger. There is no change in prices, however, and anything that a buyer could have last week, or during several previous weeks, could just as easily be had today. On the other hand, there is no particular pressure to realize, so that matters drift along from day to day almost without a shadow of deviation. Under such conditions there is nothing upon which to base predictions of change, either favorable or unfavorable, but on the contrary the indications are all in favor of a continuance of the prevailing monotony for an indefinite period. General quotations are about as follows for Philadelphia and nearby points:

No. 1 Foundry	$13.00 @ $13.50
No. 2 Foundry	12.25 @ 12.75

In the Chicago market the great bulk of the business in progress consists of local Coke Iron. Transactions in this line appear to be growing larger and some good sized purchases are reported by the largest consumers. Small lots are in excellent request, and taken as a whole the volume of business is considered quite fair for the season. The output of Pig Iron in this locality has increased considerably within the past week or two. The demand for Southern Iron continues as light as heretofore reported and prices are weak. An occasional inquiry is noted for Lake Superior Charcoal, but actual business is confined to very small lots. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @	$15.25
Local Coke Foundry, No. 1	11.75 @	12.25
Local Coke Foundry, No. 2	11.00 @	11.75
Local Coke Foundry, No. 3	10.75 @	11.00
Local Scotch	12.00 @	12.50
Ohio Strong Softeners No. 1	13.00 @	14.00
Southern Silvery, No. 1	..... @	12.50
Southern Silvery, No. 2	..... @	11.75
Southern Coke, No. 2	11.25 @	11.50
Southern Coke, No. 3	10.75 @	11.00
Southern, No. 1, Soft	11.25 @	11.50
Southern, No. 2, Soft	10.75 @	11.00
Tennessee Charcoal, No. 1	15.50 @	16.00
Tennessee Charcoal, No. 2	15 00 @	15.25
Alabama Car Wheel	18.50 @	18.65
Jackson County Silvery	15.00 @	16.00
Other Ohio Silvery	13 00 @	13.50
Coke Bessemer	12.00 @	.....

The past week has been quite an active one in the Pittsburgh district, and some heavy transactions in Bessemer Pig have taken place, the purchases being mainly by Steel makers whose output of Pig Iron does not equal their converting capacity. There is very little doing in Foundry Iron, and prices are without material change. Quotations are given as follows:

No. 1 Foundry	$11.50 @	$11.75, cash.
No. 2 Foundry	10.50 @	10.75 "

Southern markets have been quiet and barely steady during the week, there being no large sales effected, although toward the close there was more inquiry for the lower grades of Southern Iron, which it is hoped may result in more business in the future. Northern consumers of Iron want Southern Iron to improve their mixture, but are deterred from buying by the high freight rates, and there is a movement on foot to have them modified this season, but whether it will be successful time alone can determine. Prices are well sustained on the small business passing, and nearly all kinds of Iron are being taken. Some of the Southern furnaces are meeting the moderate demand quite freely, while others are not free sellers at present prices, but there is nothing to warrant any essential change in quotations. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$11.00 @	$11.25
Southern Coke, No. 2	10.00 @	10.25
Southern Coke, No. 3	9.50 @	9.75
Ohio Soft Stone Coal, No. 1	14.50 @	15.50
Ohio Soft Stone Coal, No. 2	14.25 @	14.50
Lake Superior Coke, No. 1	13.00 @	13.50
Lake Superior Coke, No. 2	12.00 @	12.25
Hanging Rock Charcoal, No. 1	17.00 @	17.50
Hanging Rock Charcoal, No. 2	16.50 @	17.00
Tennessee Charcoal, No. 1	13.50 @	14.00
Tennessee Charcoal, No. 2	12.50 @	13.00
Standard Southern Car Wheel	16.75 @	17.00
Lake Superior Car Wheel and Malleable	16.50 @	17.00

Metal Market.

Pig Tin.—Very little change in prices has taken place here despite the somewhat wide fluctuation in London quotations, and speculation has continued very tame. Purchases by interior dealers and consumers have been of somewhat larger volume, however, and made quite an impression upon stocks in first hands. At this writing the tone of the market seems to be quite steady, with 19¢ @ 19.10¢ quoted for 5-ton lots, net cash terms, and the usual premium for ordinary jobbing quantities. On distant future deliveries 19.10¢ was bid.

Copper.—More business has been done in Lake Superior Ingot, chiefly on home account, but prices have suffered slightly, some brands going at 9½¢. The Calumet & Hecla sold at that price quite freely. Business in Electrolytic has increased considerably, several million pounds having been placed, for delivery during the next six months. The prices are not divulged but the market is now quoted stronger at 9⅝¢ @ 9¾¢. Casting stock has met with better sale also and prices are steady, with 9⅛¢ @ 9¼¢ quoted for most brands. Jobbing business has been more active, and prices firm at 11¢ for small lots of Ingot from store.

Sheet Copper.—The demand from consumers shows rather more activity, and inquiries are reported as more frequent. Still, business is far below the average for the season, and the stagnation in building promises no material improvement in the near future. Cornice makers are doing little, and other consumers of manufactured Copper are buying on the most restricted scale. Prices are fairly firm, in conformity with the list.

Pig Lead.—Sales of Common Western in this market during the past week aggregate 1200 tons or more. With the increase in business there has been a further advance in prices. The dealings were at from 3.37½¢ to 3.45¢ for

round lots, up to 3.47½¢ for single carloads. At this writing there is little, if anything, on sale at less than 3.50¢. There were bids of 3.45¢ for May delivery on speculative account, chiefly by operators who went "short" of the market when it was considerably lower than it is at the present time. The demand from small consumers does not increase to any appreciable extent. Jobbers' prices are firm at 3⅝¢ @ 4¢ for small parcels and tending to the higher figure. Sheet Lead and Lead Pipe are dull.

Spelter.—The demand is exceedingly slow at present and below the average for the season. Contrary to expectations, prices have softened somewhat instead of inclining to betterment, and have ruled relatively lower than in the Western market. Ordinary brands were freely offered in round lots at 3.85¢ without stimulating purchases, and a shading to 3.80¢ brought about sales of a few carloads only. For small retail lots 4¼¢ @ 4½¢ is quoted, with but a narrow business doing.

Antimony.—The market is steady at 8¾¢ @ 9¢ for Hallett's and 10⅛¢ @ 10¼¢ for Cookson's, with the usual premium on small lots, and a moderate business passing.

Nickel.—Moderate sales have been made at 40¢, and that price is evidently full high for other than small quantities.

Tin Plate.—Disappointment over the character and volume of business is expressed by sellers, and it would appear that the market has lost rather than gained tone during the past week. Spot purchases, which are conducted on the most conservative lines, have been almost wholly of a retail character, and in some instances at prices below those generally quoted. Orders for future delivery have been placed with a degree of reserve that is remarkable, considering the low prices named. Domestic Ternes are about the only really active stock at present, the advent of mild springlike weather having created a demand for Roofing Plates for repairs and other work. The dullness generally reigning is attributed to uncertainties connected with the pending tariff legislation. Stocks are badly broken up all round, and shipments from the other side are decreasing in volume monthly. Prices are nominally firm, but really they are liable to substantial shading on desirable orders.

In reviewing the situation as regards Coke Tins, Charles S. Trench & Co., Tin Plate brokers, of this city, write under date of March 21 as follows: "The action of the Senate committee reporting Tin Plates at the rate at which the tariff bill passed the House, 1⅛¢ ℔ lb, but changing date of its going into effect from October 1 to June 30, had the effect of completely paralyzing business with the packers and can makers, but as the result of the protests that have been made from the canning industry, the Senate committee have today finally reported their tariff bill at 1¢ ℔ lb on Tin Plates, to take effect October 1, same date as Wilson bill passed the House, and this will settle the question of date, and enable can makers and packers to go ahead with their season's arrangements. It is now almost a certainty that whatever may be the fate of the tariff bill it will not affect the season's pack, and the cans for the season of 1894 will be made from Tin Plates paying the present McKinley duty. We see nothing now to be gained by delaying purchases for this season, as the nearer we get to final action on the tariff the firmer the market abroad will be, and already for the past two weeks there has been a firmer market there. It is impossible to buy July, August and September deliveries at the prices ruling for April and May from the English makers—as present prices show them in nearly every case a loss—and they expect a rush for goods the moment the Americans make up their minds about when the tariff bill will be finally passed."

A special cable dispatch from London to *The Iron Age* of March 21 reports the British Tin Plate market, both as regards home and export business, to show no improvement. Prices are still rather weak, but show no positive change. Liverpool quotations are quoted as follows.

IC Charcoal, Alloway grade	12/ @ 12/6
IC Bessemer Steel, Coke finish	@ 10/6
IC Siemens " " "	11/ @ ....
IC Coke, B. V. grade, 14 x 20	Nominal.
Charcoal Terne, Dean grade	10/ @ 10/6

Sheet Iron.—Black Iron shows less movement than last week. Prices for this material are thoroughly demoralized by keen competition and entirely in buyers' favor. Galvanized Sheets, on the other hand, are firmer in the East. Some of the larger manufacturers are reported to have withdrawn their quotations on Galvanized Iron, either from the expectation of an advance in prices or because they have contracted ahead for their product as far as they care to do at the present rates. Mills are referred to as busy and stocks not excessive.

The official statement of the Treasury receipts from internal revenue for the first seven months of the current fiscal year shows a decrease of over $12,260,000 as compared with the corresponding period of last year. The falling off was almost wholly confined to the revenue receipts on tobacco, spirits and fermented liquors. January's aggregate receipts were nearly $1,000,000 less than those for January, 1893.

The number of failures announced in the United Kingdom during the year 1893 was 10,658, of which 1045 were in the financial, wholesale, and manufacturing branches of trade, and 9031 in retail trade, professional pursuits, building, among the working classes, &c.

Chicago Report.

Scrap.—Very little Old Material is moving. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....
No. 2, such as Shovels, Hoes, &c	3.00	....
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5 ¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5⅛¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—The demand is light. Arkansas Anthracite is reported to be a new factor in the Western market, which bids fair to cut an important figure in localities west of the Missouri River, extending up into Kansas. Carload lots of 12 net tons or over are nominally quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.85

The improvement bill designed to give the Cramps room for the necessary enlargement of their shipbuilding establishment appears to be meeting with vexatious delay in its progress through the City Council of Philadelphia. The Cramps are naturally much hampered in their work by the tardiness of the city fathers in the matter, as they have long been ready to begin the extensions and improvements which are rendered absolutely necessary by the growth of their business.

The business situation in Pittsburgh appears to be better than it has of late been credited to be. The *Commercial Gazette* of that city, in an article on the trade outlook, asserts that about three-fourths of the regular forces are again at work at the iron and steel mills and factories. Among the unemployed, says that journal, 5000 are city contract laborers who are always idle during the winter, but who will be again employed by the middle of April.

CONDITION OF THE

Hardware Trade.

THERE is something of an improvement in the volume of business and a quickening in the general demand. The improvement is shown in the increase in the number of orders received by jobbing houses and manufacturers. The disposition to purchase in moderate quantities is marked and finds an illustration in the experience of a prominent File company, whose orders for the past few weeks considerably exceeded in number those of a corresponding time a year ago, though the aggregate amount of goods covered by them showed something of a falling off. The trade are purchasing seasonable specialties quite freely, this department of business being stimulated by the moderate weather which has recently prevailed. There are also indications of an improvement in the demand for Builders' Hardware, a line which has for some time been exceptionally quiet. There are few changes in price to note, but the tone of the market is weak and in many lines there is a tendency toward somewhat lower prices. This is especially the case in goods where there is considerable competition, the price of specialties which are made by only one manufacturer being more generally well maintained. In addition to the usual telegraphic advices from Chicago and St. Louis, we give below the letter from our Philadelphia correspondent which was omitted last week.

Advices from Chicago.—The Shelf Hardware jobbers report a heavy increase in the demand for general Hardware, caused by the fine spring weather. Seasonable goods are moving freely. Builders' Hardware is not so active, but a great deal of building is going on, so that a much better trade in this line is certain later in the season. Staple goods are picking up again. Barb Wire is in especially good demand. The heavy Hardware trade also shows great improvement, although even yet the volume of business is much under the normal. The orders now coming in from consumers call for an unusual variety of sizes, showing that stocks have been completely used up. Collections are getting to be considerably better than they have been.

Notes on Prices.

Wire Nails.—The excellent demand for Wire Nails which has prevailed for the past few weeks still continues, and the manufacturers are receiving many orders from the larger and the smaller trade. As a result, they are fully occupied, and in some cases are unable readily to supply the wants of their customers as promptly as desired. The market continues steady in the matter of price on the basis of $1.10 for carload lots at mill, but it is understood that this figure can still be slightly shaded on especially large and attractive orders. The manufacturers, however, appear to be maintaining prices quite firmly, notwithstanding the fact that rumors are current of a weakness in the market, which we have been unable to verify. Small lots from store in New York are held at $1.25 to $1.30.

Advices from Chicago.— Although rumors are in circulation of weakness in Wire Nails, there is very little evidence in sight here. The reduction in freights appears to have had more effect in lowering prices than an attempt to secure business by the manufacturers. The factories all seem to be full of orders, and they have been known to refuse positive offers at concessions from prices hitherto current. One large establishment was compelled during the week to put its machines on double turn in order to make prompt shipments to consumers, who have begun to clamor for deliveries on their contracts. Jobbers report a considerably better movement from stock. Under these circumstances it would appear singular if prices should weaken. Ordinary factory lots continue to be quoted at $1.15, Chicago, while small lots from stock are selling at $1.20 to $1.25.

Cut Nails.—The demand for Cut Nails is fair, though not specially heavy, but manufacturers report an increased inquiry and the promise of a good business in the near future. The Eastern manufacturers are maintaining prices pretty steadily and adhering to their policy of quoting prices for Nails delivered at the principal points in their territory. The following are their quotations for carload lots delivered at the points named: New York, Albany, Boston and Savannah, $1.05; Buffalo, $1.02, and Harrisburg and Philadelphia, $1. Concessions are made from the above prices in some instances on attractive orders or where the manufacturers come into competition with Western makers. The price from store in New York is $1.15.

Advices from Chicago. —Manufacturers report about the same condition of affairs as stated during the past three or four weeks. The demand is considered quite good under the general trade conditions and the distribution of Cut Nails is still spreading over a wider area. Prices are as before on the basis of $1.05, Chicago, factory for lots on 60-cent average. Small lots from stock are selling at $1.15.

Barb Wire.—A very satisfactory condition is reported in the Barb Wire market, both in the matter of price and demand. The volume of business is large and the mills are full of orders, so much so that in some cases they are unable to make shipments with sufficient promptness to meet their customers' requirements. Prices are steadily maintained on the following basis: Carload lots of Galvanized Four-Point, Pittsburgh, $2.15; Cleveland, $2 20; Cincinnati or Allentown, $2.25 ; Chicago or New York, $2.35, with an advance of 5 cents per 100 pounds in less than carload lots.

Advices from Chicago.— Manufacturers report a great deal more inquiry for Barb Wire, as well as plain Wire. They are exceedingly gratified at the manner in which orders are coming in and report stiffer prices. If the movement continues, as from present appearances it will, the largest manufacturers will in a short time be completely overwhelmed with business. Quotations are $2.35 to $2.40 for small lots of Barb Wire from stock, and $2.25 to $2.30 for carloads.

Wrought Iron Pipe.—The volume of business in Wrought Iron Pipe is reported fair, but competition between the manufacturers is active, and as a result prices have settled to a comparatively low level, concessions being freely made on large orders.

Rope.—The demand for Cordage generally is light and prices are irregular and somewhat weak. Quotations are on a basis of 6½ cents for Manila, 5 cents for Sisal and 5 cents for New Zealand, slight concessions being sometimes made, but only on especially large lots.

Pocket Oilers.—The Ægis Pocket Oilers manufactured by the Scovill Mfg. Company, Waterbury, Conn., are sold, either style, at $8 per gross, net.

Watch Carrier.—Burleigh's Bicycle Watch Carriers, manufactured by Geo. K. Burleigh, Tilton, N. H., are sold at 75 cents each, or with a 2-inch clock at $2 each, from which prices a discount of 33⅓ per cent. is allowed.

Relief Wringers.—Relief Wringers, manufactured by the American Wringer Company, 99 Chambers street, New York, are sold at the following prices, which are subject to a discount of 2 per cent. for cash in ten days :

Without Cog Wheels.

No.	Size of Rolls.	Per dozen.
2....	10 x 1¾.....	$20.00
3....	11 x 1¾.....	24.00
4....	12 x 1¾.....	28.00
5....	14 x 1⅞.....	37.00
6....	16 x 2.....	46.00

With Cog Wheels.

No.	Size of Rolls.	Per dozen.
22....	10 x 1¾.....	$22.00
33....	11 x 1¾.....	26.00
44....	12 x 1¾.....	30.00
55....	14 x 1⅞.....	39.00
66....	16 x 2.....	48.00

Glass.—While there is little if any improvement noticed in the demand for Window Glass, there is a reported tendency toward firmer prices by manufacturers than for some time past. It is understood that 88 per cent. discount for single, and 90 per cent. discount for double strength Glass, prices that have been offered by Western manufacturers and jobbers, are not now obtainable. Pittsburgh quotations remain the same as last week—85 and 10 and 5 per cent. discount for single, and 85 and 20

per cent. discount for double strength Glass. Plate Glass is still sold at very low prices owing to the sharp competition between manufacturers.

Old Metals. — Business continues quiet. The demand does not increase, and prices keep at a very low level. The following quotations represent about the prices paid by New York dealers :

Heavy Copper	℔	lb	7¢
Light and Tinned Copper	℔	lb	6¢
Heavy Brass	℔	lb	5¢
Light Brass	℔	lb	4¢
Lead	℔	lb	3¢
Tea Lead	℔	lb	2½¢
Zinc	℔	lb	2¼¢

Old Rubber.—There is very little doing in Old Rubber, and prices remain at the low level they have held for some time past. The following quotations represent about the rates paid in New York :

Car Springs, ton lots, ℔ lb.	@	$0.03¼	
Rubber Shoes, carloads, delivered at factory, ℔ lb.	@	.03	
Rubber shoes, less than carloads, ℔ lb.	0.02¼	@	.03⅛
Large Hose, ℔ ton	@	9.00	
White Wringer Rolls, ℔ lb.	@	.04¼	
White Syringes, ℔ lb	@	.05	

Trade Notes.

The big five-story tinware factory of S. A. Ilsley & Co., York and Adams street, Brooklyn, N. Y., was destroyed by fire on March 18. The loss was a total one, estimated at about $300,000, but fully covered by insurance. Some 350 hands are thrown out of work. Messrs. Ilsley & Co. are manufacturers of Decorated Tinware.

The Water Gas Heater Company were incorporated recently at Baltimore, Md., by Samuel Childs, J. Henry C. Watts, E. Parkin Keech, Jr., Wm. F. Beasley and John T. Mason, R., with a capital stock of $100,000. The company will manufacture cooking and heating apparatus.

The Day, Ward Company, composed of Geo. E. Day, A. G. Ward and W. C. Winfield, at Warren, Ohio, will, it is reported, manufacture Steel Cased Bathtubs, Blacksmiths' Blowers and other articles for which patents have been obtained.

The New Philadelphia Sheet Mills New Philadelphia, Ohio, were closed down for a few days last week as a mark of respect to E. C. Smith. This week the whole plant, consisting of five sheet mills and sheet bar mill, is in operation. The galvanizing department of this company is now in operation.

The sheet mills and galvanizing shop of the Cambridge Iron & Steel Company, Cambridge, Ohio, are running at their usual gait. It is a fact worthy of note that a stoppage in these mills is a very rare occurrence.

Curtis & Curtis, Bridgeport, Conn., advise us that they are very busy filling large orders for Forbes pipe machines received by cable from England.

The Peck, Stow & Wilcox Company, Southington, Conn., have under consideration plans for the construction of a new malleable iron foundry and a new gray iron foundry. In former years the company manufactured their own iron and have decided to renew operations in this line.

The Manufacturers' Association of Kings and Queens Counties held another meeting Tuesday evening, March 20, at the Union League Club, Brooklyn, for the purpose of effecting a permanent organization. The following officers were elected : H. B. Haigh, president ; William H. Nichols, first vice-president ; Ernest C. Webb, second vice-president. In addition to the six directors elected March 6, for the purpose of incorporating the body, the following gentlemen were chosen to complete the board : D. R. Morse, Thos. C. Smith, John H. Hanan, Robert Dunlap, John H. Schuman, F. W. Wurster, D M. Somers, E. W. Bliss, J. Adolph Mollenhauer, A. G. Jennings, F. J. Logan, Cord Meyer, Jr., William Vogel, C. N. Chadwick. The balance of the board consists of H. B. Haigh, Lowell M. Palmer, William H. Nichols, E. Dwight Church, Walter L. Pierce and Ernest C. Webb.

The Government is finding some difficulty in securing the necessary land on which to build the proposed naval dry dock at Algiers, near New Orleans, La. The landholders owning the desired property are asking such extortionate prices for it that expropriation will probably be resorted to by the Government.

The largest vessel on the lakes was successfully launched at the Wyandotte yards of the Detroit Dry Docks Shipbuilding Company, Detroit, last week. She is 362 feet over all, 42 feet beam and 25 feet in depth. The vessel has been built for a syndicate, and is designed to carry 4000 net tons of cargo.

Bids have been called for by the Lighthouse Board for the maintenance of buoys along the New Jersey coast, the contract to be for one year from July 1 next. Bids must be in by April 1.

Andrew Carnegie's offer to duplicate every dollar contributed for the relief of the poor in Pittsburgh, before March 1, cost him something over $125,000.

It Is Reported—

That T. T. Flynn and Angelo Walker have bought the stock of Hardware of Frank Hall of Prattsburg, N. Y., and will continne the business. Mr. Flynn was formerly a member of the firm of G. W. Peck & Co., and Mr. Walker a clerk in the same establishment.

That Charles H. Clark, Hardware merchant, of Kennebunkport, Maine, is closing out his stock.

That the Miller Hardware Company, Bay City, Mich., have been incorporated, with a capital of $100,000.

That the Hardware store of P. Guilloz, 148 Grand River avenue, Detroit, Mich., was entered by burglars on the 28th ult. and robbed of $40 worth of Cutlery.

That the Hardware store of A. Morehouse, Fenton, Mich., was burglarized on the 4th inst.; $50 to $60 worth of Hardware was carried off by the thieves.

That the firm of Darby & Reed, Hardware dealers, North Adams, Mass., have been dissolved by the retirement of Mr. Reed. J. M. Darby has purchased his partner's interest in the concern.

That the Stoddard Hardware Company have been incorporated at Minneapolis, Minn. The capital stock is $50,000. The incorporators are F. L. Stoddard, G. P. Derickson and W. B. Miller.

That the store and Hardware business of the late James Nutter, at St. Peter, Minn., have been purchased by his sons, William, Emmett and Geo. F. Nutter, and hereafter the firm will be known under the style of Nutter Bros.

That the Hardware store of Robie & Peasley, Greeley, Col., was entered by burglars on the 1st inst., and $100 worth of Knives and Revolvers stolen.

That A. P. Hogle's Hardware store, at New Palestine, Ind., was damaged by fire on the 28th ult.

That T. Perkins' Hardware store, Manchester, Vt., was destroyed by fire on the 2d inst.

That the Hardware store of Haley & Chesebro, Stonington, Conn., was broken into by thieves on the 28th ult. and $150 worth of Cutlery, &c., taken.

That J. A. Collet's Hardware store, at Morgantown, Ind., was destroyed by fire on the 3d inst.

That the Hardware firm of Anderson & Farton, Stoughton, Wis., has been dissolved by mutnal consent, Mr. Farton retiring. Mr. Anderson will continue the business.

That S. O. Stillman has retired from the Hardware business, at Galena, Ill., after 40 years' connection with it. His successors are W. W. Stillman, his son, and Wm. H. Stahl. The firm style will be Stillman & Stahl.

That Mr. Hemphill of Forreston, Ill., has opened a Hardware store at Polo.

That Newark & Drury, Cadillac, Mich., will put in a stock of Hardware at McBain.

That Edgar John of Maxwell, Iowa, has purchased the interest of Webster Bishop in the Hardware firm of Willard, John & Co., Cambridge, Iowa.

That Shidler & Shidler, Canton, Ill., have sold their stock of Hardware to Mitchell & Moore and have removed to South Bend, Ind., where they will probably re-enter the Hareware business.

That Mr. Holcomb of Holcomb & Evans, Creston, Iowa, has sold his interest in the firm to I. N. Fields, who, with George Evans, will hereafter conduct the business under the firm name of Evans & Fields.

That the Byers Hardware Company lost over $18,000 by a large fire at Kaslo, B. C., on the 25th ult.

That George Henderson has purchased the interest held by the late A. J. Chrysler in the Hardware firm of Chrysler & Caskey, Ellis, Kan.

That R. G. Dalton has sold his interest in the Hardware business at La Junta, Col., to his partner, A. H. Cawthron.

That Dickson & Taylor have opened a new Hardware store at Armour, S. D.

That J. N. Duily's Hardware store, at Cleghorn, Iowa, was burglarized on the 3d inst. Fifty dollars' worth of Revolvers and Razors were stolen.

That the McQuesten & Sawyer Company, Muscatine, Iowa, have been incorporated. The authorized capital is $50,000. The Board of Directors of the company comprises W. W. McQuesten, S. P. Sawyer and S. F. Sawyer.

That Wolverton & Byrd's Hardware store, at Spokane, Wash., was badly damaged by fire on the 3d inst.

That George Pearce has sold his Hardware stock, at Fisher, Ill., to F. B. Vennum.

That the Tompkins Hardware Company, Cripple Creek, Col., have established a branch store at Victor.

Locating a Heating Boiler.

After computing the amount of radiating surface necessary to heat a building and locating this in advantageous positions, the size of boiler necessary to supply the heat to the radiators and boiler location next demand attention. Now, as the location of the boiler may greatly affect the size of mains required to carry steam to the various parts of the building to be heated, and as the size of the mains is a notable element in the cost of erection as well as the performance of steam or hot water heating work, more careful attention to judiciously locating a heating boiler with relation to the distribution of the radiators would result in pecuniary gain to a large number of beginners in these kinds of heating work. The remark applies more particularly to those whose experience is limited, because those who have been long in the business have generally learned the lesson. An inspection of steam and hot water heating plants, particularly in country places, where such plants have been erected mostly by local fitters of limited practice in this class of work, will show many examples of a lack of due consideration of the effect upon cost of the selection of a judicious site for the boiler. A well remembered instance is that of a country church wherein the contractor for steam heating apparatus might have saved easily $75 to $100 by a better chosen boiler position.

A Reason Why Mistakes Are Made.

One potent reason why such mistakes are made by inexperienced fitters is that they give too much heed to the counsel, in this regard, of the salesmen from whom they purchase their boilers. In the absence of definite knowledge of the peculiarities of any particular job, the only rule that can be given safely is to set a boiler as near as convenient to the smoke flue with which it is to be connected. And this is the rule which salesmen generally lay down to their customers. It is true that the draft of a boiler furnace is more certain to be good in this position than where a long smoke pipe connection is required. But in a properly constructed boiler, having a total flue area ample to dispose of the gases of combustion, proximity to the chimney is not a factor of such prime importance in boiler setting as it is sometimes regarded. Instances of work done by firms of high reputation and which have been highly successful in operation where the boilers have been set anywhere from 20 to 50 feet from the chimney might be easily cited. It must be confessed that many boilers designed for domestic heating would act sluggishly under such conditions; but there is no law compelling a contractor to use such a boiler, and in cases where placing a boiler close to a chimney entails an extra expense for piping he should seek a manufacturer who is willing to guarantee satisfactory draft in boilers of his make in positions within reasonable distance from chimney flues.

Goods Used in Mexico.

The following interesting letter is received from Philip G. Roeder, 664 Cedar avenue, Cleveland, Ohio, who has spent a dozen years traveling as a manufacturers' agent in Mexico:

In reply to your inquiry as to the demand in Mexico for American goods in the lines of the patrons of your valuable journal, I will state that I have spent several years in our sister republic, animated by patriotism and the greed of gain, introducing American wares. The very poor in Mexico use few or no utensils of iron. Small earthenware (charcoal) ovens or "brazeros" take the place of our stove, and pots, jars and plates of the same material serve to cook their beans and stew their meats. A piece of sheet iron placed over the brazero is all they need to fry their tortillas (corn pancakes) or their "enchilados." In the cities, however, modern improvements are much in vogue. The hotels and large restaurants are using ranges to some extent, and the oil and gasoline stove finds ready sale, especially during the winter months. Houses in Mexico are not built with chimneys, hence they have no fire places, and coal or wood stoves could not be used. Oil and gasoline stoves are thus used for heating purposes, the temperature in the early morning falling very low at times. Vienna enameled ware sells readily in the capital and in the larger cities, and I see no reason why our American stamped ware should not take its place. A portable sheet iron baker or oven, with a small chimney attachment, one that could be set over the opening above the charcoal fire of the stationary brick ovens of the Mexican kitchens, would be a good seller, as they really have no means of roasting a fowl or large piece of meat. I know of one party who has sold several carloads of such ovens, gotten up by himself, at a good profit, too. A hint that might prove valuable not only for Mexico, but for all hot countries, is that refrigerators are used only by the saloon and restaurant trade; private families do not use them to any extent. The lady of the house, followed by her servant, goes to market each morning to buy her necessaries for that day and that day only; nothing is ever kept over. Vegetables and fruits are to be had fresh all the year round, therefore no one lays in a supply ahead. Small ice making machines are in great demand, such as are not too expensive or bulky. These sell all over the interior table land and in the *tierra calienta* (hot land). Mexico City has good water works, and has plenty of pressure in the pipes, but the sewerage is very deficient. The city lies as in the bottom of a soup plate, so to speak. When the drainage canal is completed, which is promised for the near future, the city's sewage can flow off instead of having to be raised by powerful pumps. Then there will be a demand for modern plumbing.

Corrugated iron is used very extensively in Mexico for roofing. Half the year it is dry and the other half it rains in torrents, and iron stands it best. Cornice and structural iron is used further north to a larger extent, perhaps, than it is used here now. Windows are all provided with balconies having fancy railings, and the corridors of the inner courts are also handsomely ornamented. Iron urns for potted plants are used largely.

It will take some time to get American goods properly introduced, as this market has been so long neglected and Europe is in the saddle. However, by dint of circulars and catalogues, and by personal drumming, we are getting there, and American machinery in the coffee and sugar lines, cotton, grain and general farming lines, is taking the lead. Our tools of nearly every description are sought for. The Mexican is artistic, and he likes our tools because they are light, well made and handy. American trimmings are used in all new buildings, and bronze butts, &c., are taking the place of the old fashioned hand forged hinge and ponderous lock. I will not enumerate the carriages and wagons, the furniture, glassware and jewelry, sewing machines, mining machinery, railway supplies, wire, &c., that find a market here. Bicycles are the rage, and in Mexico can be used the year round. Steady hammering, the study of Spanish and a little unbending and concession upon the "you do the business our way" style of the average American, will find the Mexican and his brother further south *ready and willing* to purchase the goods his northern neighbor has to offer in exchange for the products of his own sunny clime.

A Fire Proof Dwelling.—We have referred at various times to the increasing use of structural shapes in the smaller classes of buildings. The very

low cost of steel has enabled it to be introduced to a gratifying extent in structures of a business character, apartment houses, &c., in which wood would continue to be used if much difference existed in cost. The fact can now be made public that the first dwelling house of steel construction is in course of erection in Chicago. It is to be strictly fire proof and is expected to mark the beginning of a new era in thia type of buildings. The house is not a cheap one, as it will cost close to $40,000, but the use of steel and the fire-proofiog have added but $2000 to the cost if built in the old way. The arcbitecta are Beers, Clay & Dutton of Chicago, who have designed and erected many notable buildinga in that city and in other parts of the country. They may justly be considered pioneers in this new field.

Cupola Heat and Quality of Cast Iron.*

W. J. KEEP, DETROIT.

The statement was made some weeks ago that a casting made at the last part of a heat was stronger than if made at the first part. An analysis proved that the iron from the early part of the heat contained 2.80 per cent. of silicon while that from the laat carried 2.70 per cent. Thia would not account for any variation in atrength. We are apt to jump at conclusiona. It has generally been stated that aa the cupola bccame hotter the iron would contain more silicon, but thia analysis and those whlch I shall present both ahow thia to be an error. This is alao a case where we are deceived by the fracture, for the grain of the casting made early in the heat is closer and lighter in color than that made later on. We shall prove that the difference is caused by the variation in heat at which the iron waa melted, not the heat of the iron when it was put into the mold.

When a cupola begins to melt, everything is comparatively cold. There is no alag and the blast has free access to all parts of the cupola. The dropa of melted iron are exposed to this cold blast as they fall among lumps of fuel and on the sand bottom, all of which are colder than the fluid metal. The firat iron drawn from a cupola has been melted under such conditions, but in half an hour the melted iron is covered with a protecting slag and the heat increases until the blast is off. The following series of teats are each averages of from three to aix test bars, made at various times, to determine the influ ence of varying heat. In each case the first set of test bars was poured from the first iron after about 400 pounds had been taken. The last was in each case taken after the wind was off, and just aa slag began to show at the tapping hole. The intermediate teats were taken at regular intervals, the heat lasting about 3½ hours. In some cases, therefore, a test was taken every 20 minutes, and in others they were over an hour apart. In series IX, X and XI the tests were about one hour apart. Two things are evident: There is no uniform variation in strength. There is in each case a decreaae in shrinkage and chill.

In calculating the mixture of the pig iron alone I used analyses which I have of each iron used. To arrive at the regular mixture 40 per cent. of remelt is added, and deductions are made for loss of carbon and silicon, and addi-

Tests of Iron During the Melt.

To reduce the strength of these test bars to a bar 1 inch square and 12 inches long multiply by eight. Each of the above tests (a set) consisted of five test bars ½ inch square and 12 inches long, and a companion flat bar 1 inch wide, 1-10 inch thick and 12 inches long. Three square bars are broken in a special autographic dead load testing machine, and two square bars are broken in an autographic impact testing machine. Only averages are recorded.

The following analyaes by Cary & Moore were of the bars 788 and 791, aerles IX:

Number test.		Total carbon.	Graphite.	Combined carbon.	Silicon.	Sulphur.	Phosphorus.	Manganese.
788	Actual analysis of test bars	2 910	2.280	0.630	3.220	1.025	0.123	0.49
791	Actual analysis of test bars	2.950	2.470	0.480	3.140	1.055	0.100	0.47
791	Calculated composition of mixture	2.476	2 110	0.366	3.130	0.911	0.078	0.450
791	Calculated composition of pigs alone	2.540	2.181	0.359	3.186	0.902	0.064	0.456

* A paper read before the Western Foundrymen's Association.

tions for the gain of phosphorus and sulphur, which are expected to take place. Evidently the pig iron is higher in carbon and phosphorus than the original analyses show, and more sulphur has been taken from the fuel than I calculated for. I did not figure on cumulative percentage of sulphur, which this and previous analyses indicate should be figured where a large portion of remelt is returned to the cupola each day. Since writing the above I have received four sulphur determinations of other tests of this same mixture, but made on other days, and the average of the four is 0.081, showing that the day that series IX was made a car of coke was used with the sulphur higher than usual.

It will be noticed that the tests for series IX show less strength than those of series X and XI. The reason for this is that each test in series IX was poured as soon as the iron was taken from the cupola, while in making series X and XI the molder poured other work from the ladle and then used the last iron for the test bars. Iron grows stronger as it stands in the ladle. To show this fact more clearly the following four tests were poured from a single ladle with 28 pounds of iron, the tests being poured one minute apart, or three and one-half minutes from the first to the last. Between times the ladle rested so that the iron could cool, but the iron was not agitated:

Number test.	Series XII.	Dead load. Strength.	Dead load. Def.	Impact. Strength.	Impact. Def.	Shrinkage. Square.	Shrinkage. Flat.	Chill.
784	First test.....	All from one ladle of 28 pounds cupola iron.	388	0.23	348	0.24	0 128	0.143	0.02
785	Second test.....		393	0.21	331	0.23	0.128	0.140	0.02
786	Third test.....		424	0.21	406	0.25	0.128	0.135	0.025
787	Fourth test.....		466	0.24	347	0.24	0.129	0.136	0.02

The iron of series IX being poured immediately after it was caught corresponds to test 784 of series XII, while those of series X and XI are more like 786 and 787.

Cary & Moore found the silicon of test 784 to be 3.46 and the sulphur 0.079, while test 787 has silicon 3.45 and sulphur 0.083. You will notice that the shrinkage and chill of the square test bars do not change, though the more sensitive flat test bars show some decrease. The difference in strength in this case is in no way occasioned by change in chemical composition, but is no doubt due to the internal stress in the first test bar (784) caused by a rigid shell forming about very hot metal, which latter in shrinking causes a stress between the grains, while the last test bars (787) are so cold that the metal at the center does not shrink much. The difference is strength is therefore due to the physical structure.

Now recurring to the analyses of 788 and 791, we should not be too sure as to indications without other analyses of other tests. But the similarity between these silicons and the silicons (7.80 and 7.70 per cent.) first referred to lead us to expect similar results again. The indication is that the carbon burned out slightly before the slag covered the iron, and it is quite certain that we get all the silicon in the casting while the cupola is cold, but that it was burned out somewhat after the cupola became hot. Also it is evident that less sulphur is taken up in a hot than in a cold cupola.

The combined carbon is slightly greater in the iron having the most silicon, showing that the increase in combined carbon is due to the conditions in the cupola, and not to chemical composition. The increased chill is also due to these conditions and not to combined carbon or to sulphur.

Chill is probably a unton of carbon and silicon and iron under a peculiar cooling influence, and is not the same thing as the determined combined carbon. With the cooling conditions present at the beginning of this heat, the iron is in such a state that it will take a chill, and often such iron as 788 will solidify with the exterior surface a soft gray, while the interior will be a perfectly white core, the silicon being the same in both. Iron that favors a white core comes at the beginning of the heat when silicon is high, but it is a rare thing to get the conditions that will cause it. As soon as the cupola is hot, half an hour after the iron comes down, such a union cannot be formed.

In tests of pig iron it is difficult to trace chill to the influence of combined carbon, or to any other element. We might perhaps compare the conditions existing when the test bars 788 were made to a blast furnace with cold blast, which makes a chilling iron. The conditions afterward are a little more like a furnace with hot blast, which makes an iron with less chill. The question of sulphur should be settled by these tests and analyses. The sulphur is higher than usual, but there never were better castings made, and there is not a sign of chill or hardness or strain. This is the same mixture from which the strong castings were made for which I asked a chemical prescription a few weeks ago.

Understand that I do not say that the sulphur is the cause of the strength of these castings. I only claim that the quantity ordinarily found in gray castings exerts no influence, and can be ignored. Instead of laying the blame on sulphur in the fuel, it should be ascribed to lack of carbon in the fuel, which produces a cold cupola, which is likely to make just such iron as 788.

I do not wish to discuss the sulphur question at this time, because I shall bring forward a large amount of testimony to prove the correctness of my conclusions, at the meeting of the Philadelphia Foundrymen's Association on April 4. The good qualities of this iron are not due to chemical composition but to physical composition, which can always be brought about by careful mixing.

The casting 791 has as low shrinkage as can be found in any ½-inch test bar from a cupola. This iron had remained in the bottom of the cupola three or four minutes after the wind was off. Some chemists may figure that the slight variation in the chemical composition would account for the variation in the physical characteristics, but we shall, at another time, prove that this is not so. The change is chiefly if not wholly due to physical effects, brought about by the change in heat in the cupola. Very great changes in strength can be obtained by manipulation. From this same mixture I obtained the strong test bar which has been referred to, by simply a slight agitation of the metal in the ladle with a steel bar for 30 seconds. These tests illustrate the sensitiveness of a ½-inch test bar, which by its variations in shrinkage will indicate the exact influence of each chemical element in the iron, and is the most sure method of controlling a foundry mixture.

I will say only a word regarding the papers introduced at the last meeting. I am not in any way opposed to chemical work; I could do nothing without it. None of the conclusions of this paper could have been reached until the full analyses of the test bars were received. Chemistry alone has made little progress in the study of cast iron, and many of its conclusions have been wrong. With the ordinary large test bar physical tests have taught but little. With a small sensitive test bar, by the help of chemical analysis, very much has been done. What I claim is that a labratory in an ordinary gray iron foundry, with a chemist such as would naturally be employed, would accomplish less than could be done through the use of the ½-inch test bar alone. The manner in which some founders use a little chemical data is very discouraging. I fully agree that each founder should have a thorough chemical education, but they should acquire the habit of using it in a practical way. For example, Mr. Wheeler proposed a theory that all iron coming from a furnace contained an equal amount of sulphur and that the more fluid No. 1 iron allowed its sulphur to escape, &c. Now, he has the iron running each day, and has a labratory. Why should he, of all others, theorize regarding sulphur when he could prove it and thereby add to the general knowledge?

Mr. West claims to have a laboratory, and yet in a letter to the *Iron Trade Review*, February 22, 1894, ascribes the variation in strength which is the subject of this paper to the variation in the metal charged, claims that his records show more silicon in a hot cupola and then reasons from this fact. If such men jump at conclusions with a fully equipped laboratory at their command, it is discouraging for others to begin their use.

Mr. Bolland theorizes regarding chemistry, with which he owns he is not very familiar, and then says that personally he found no trouble in controlling his mixture by test bars. This personal experience of a practical founder is worth more than all that he imagines could be done.

The annual meeting of the New York Metal Exchange occurred last week. The reports of the officers showed that the trade in metals had been retarded by the general business depression of the past year. The condition of the Exchange's finances was reported as good. The membership has increased to 300. It was announced that an offer of $70,000 had been refused for the exchange building, which was purchased eight years ago for $42,000.

Galvanizing works in New York have been quite busy for the last week or two after six or eight months of almost unexampled dullness.

THE LETTER BOX.

Flat Seam Roofing Questions.

From J. F. S., *Lakewood, N. J.*—Having seen the letters of "S. P. K." and "G. R. J." in *The Metal Worker* January 27 and February 10, I contribute the following from my experience. It takes about 5 minutes to notch or cut the corners off a box of 14 x 20 tin, about 23 minutes to edge it, and about 3 minutes to book it, putting 28 sheets in a book, but I think better time can be made by a man in practice. We easily average 300 to 350 square feet of 14 x 20 tin on a plain roof in a day, using 3½ pounds of solder to 100 square feet and four nails to a sheet. I have seen 538 square feet of 20 x 28 tin put on in nine hours, four nails to a sheet, on a roof that had one chimney, a gutter strip and a back strip finished under weather board of a house. I think a man and a helper using "kickers" can easily average 100 square feet per hour all day on a roof that does not pitch more than 3 inches to the foot. It is some years since I worked where flat seam roofing was put on in strips 20 inches wide, but I think that on hipped roofs I can lay as much tin in a day by the sheet at a time method, and am sure that it would make a much firmer and less noisy job. When the tin is expanded in summer and the wind is blowing a roof will rattle that has a 19-inch space that is not anchored to the sheathing, but the rattling cannot occur with a roof of 14 x 20 tin put on one sheet at a time. No doubt many roofers are satisfied with their methods of getting the tin ready and putting it on, and could give some interesting details in *The Metal Worker*. The question is will they kindly do it?

The Hyde Park Boiler.

From D. E. M., *New York*—I notice an inquiry in *The Metal Worker* of March 24 for the manufacturer of the Hyde Park hot water boiler. This boiler, I think, is made by E. D. Howatt, Hyde Park, N. Y.

Tempering and Threading.

From E. E. H., *St. Louis, Mo.*—Will *The Metal Worker* please tell me what process is used in tempering taps and dies. Please give me a rule to use in figuring out the wheels to cut different threads on a lathe, also a rule for cutting gear wheels on a gear cutting machine?

Answer.—Successful tempering is only accomplished as the result of closely observed experiment. After the article to be tempered is finished it is hardened by heating to a red heat and plunged into cold oil. It is then heated and the hardness drawn until the desired color is shown, which is some tinge of the color commonly known as straw color, when it is again cooled in oil.

All lathes of modern construction are provided with an index plate, with which the following rule is generally used:

Read from the lathe index the number of threads per inch cut by equal gears and multiply it by any number that will give for a product a gear on the index; put this gear upon the stud, then multiply the number of threads per inch to be cut by the same number and put the resulting gear upon the screw.

Example: To cut 11½ threads per inch. We find on the index that 48 into 48 cuts 6 threads per inch.

$6 \times 4 = 24$, gear on stud,
and $11\frac{1}{2} \times 4 = 46$, gear on screw.

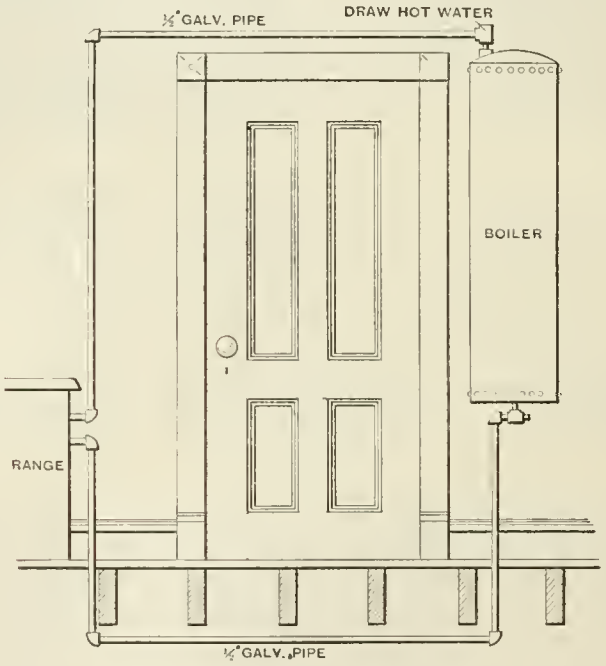
Any multiplier may be used so long as the products include gears that belong with the lathe. For instance, instead of 4 as a multiple we may use 6.

Thus, $6 \times 6 = 36$, gear upon stud,
and $11\frac{1}{2} \times 6 = 69$, gear upon screw.

Gear cutting machines are also provided with an index having holes arranged in concentric circles around a center, each circle having a different number of holes. In use a pin enters these holes to hold the blank gear stationary while the notch forming the side of two teeth is cut. To use the index divide the number of teeth to be cut into some number on the circles on the index plate which can be divided without a remainder and the quotient will be the number of holes apart on that circle the pin must be inserted to cut the gear. For instance, if 19 teeth are wanted the circle containing 76 holes can be divided and 4 will be the result without remainder, consequently in using the machine the pin must be inserted in every fourth hole on that circle to cut 19 teeth.

Small Air Bound Pipes.

From BRAMHALL, DEAN & Co., *New York.*—Referring to the letter of "E. J. S.," page 30 of *The Metal Worker* of March 17, I take the liberty of inclosing a tracing showing the ordinary manner of connecting such jobs. The outlet used for drawing hot water of course relieves the pipe of air from time to time as water is drawn. I believe boilers were connected in this manner long before the "side coupling," as it is called, was used on the boiler. It is not always that a closet door is between the range and boiler, but it frequently happens that a window prevents the carrying of the hot water circulation to the boiler, so that this plan of getting over the top is adopted. As you say, the "pipe is too small," and possibly the water back may not be of the right sort.



Small Air Bound Pipes.

Beating Up Sheet Lead.

From F. W. H., *Lancaster, Pa.*—I would be glad to receive information in *The Metal Worker* as to what method, material or liquid should be used for stretching or forming sheet lead that will give better results than simply using a dresser.

Note.—Our sheet lead working readers are invited to make suggestions on this subject. A tank about 36 inches square and 10 inches deep that is very true in form is held at the New York Trade School as a very excellent piece of work by one of its pupils. This was

beaten up without the use of any other material than the lead, and the tool used was a dresser. Such a piece of work is very tedious, and requires much skill and judgment.

Beyond a Syphon's Limit.

From V. & B., *Binghamton, N. Y.*—We send *The Metal Worker* a diagram of a line of water pipe by which we desire to syphon water from the creek over a hill. It is our impression that it will not work. At a point A on the diagram there is a creek, and it is proposed to dam it so as to form a pond, then water is to be taken through a 2-inch pipe over the hill to a point marked C. From the level of the creek to the top of the syphon is 70 feet and from the top of the syphon to the point of delivery is 170 feet. There is a spring some 50 feet higher up, and we have shown a 1¼-inch pipe running into the syphon pipe about 10 feet from the top to start the syphon working. Another pipe of the same size, from the spring, connects with the syphon about 80 feet below the top of the syphon. Which would be the better place to connect this pipe, and would it be practicable to take out sprinkling pipes from the main before reaching the level of the water in the creek?

Answer.—We have not reproduced our correspondents' diagram, as the description is sufficient. The principle on which a syphon works is that the water falling through the long leg has a tendency to create a vacuum at the top of the syphon, which is filled by water from the short leg being forced up by the atmospheric pressure on the surface of the water in which the short leg of the syphon is immersed. The limit to which water can be raised by atmospheric pressure at the sea level under favorable circumstances is about 34 feet, consequently a syphon of the length here described would not work. The idea of connecting a pipe from the spring to start the syphon is ingenious, and in all probability would prove efficient if the syphon were within working limits. To connect a sprinkling pipe with the long leg of the syphon before reaching a point below the level of the water supply would destroy the syphon, and if connected at a point where it did not destroy it, it would only produce a very weak flow of water and would not have sufficient force to form a spray.

Hot Water From Cold Faucet.

From OLIVER TWIST.—In answer to the inquiry of "L. J. P." in *The Metal Worker* March 17, would say that the particulars given are very few on which to base an intelligent opinion. I have known such a trouble to arise from the pipe inside of the boiler being attached to the wrong connection, or attached to the connection marked hot in the sketch. If upon investigation the boiler pipes are found to be properly connected, then the fault is due to lack of water pressure. The cold water going to the boiler must flow past the branch to the sink, and if the faucet is opened the pressure on the system is instantly reduced, and so much that the hot water backs along the piping from the boiler to the faucet.

From H. I. M., *Alabama.*—Having seen the inquiry of "L. J. P." in *The Metal Worker*, March 17, under the head of "Hot Water From Cold Faucet," I thought like the Hoosier from Indiana that it was about time that Alabama had been heard from. With the low pressure reported and the cold faucet so close to the boiler, that hot water should come from it is not strange. The hot water simply backs into the supply pipe and over to the faucet shown in his sketch. I have known hot water to back along the supply pipe to the hydrant in the yard where the boiler was small and the water back in the range had a great capacity. One remedy is to cut out the short branch to the faucet and run a pipe to the faucet from a point further back on the supply. Another way would be to put a check valve on the supply pipe, but this might cause a burst in some part of the system if it was full of cold water and a good fire was started unless some provision was made for the expansion of the water as it became heated. A safety valve could be placed on the hot water pipe at the sink so that when it was opened by expansion the overflow would do no harm. Another way would be to run a pipe from the boiler to the tank and turn the end down over it so that air and steam could escape from the boiler and the overflow from expansion would fall into the tank. Now let some other representative of the great Southeast do his duty and show the readers that the great Northwest is not the only section that is entitled to be called great.

Fails to Bake on Bottom.

From WM. D. SOUTHARD, *Peekskill, N. Y.*—On page 30 of *The Metal Worker* of January 20, W. S. Guelph complains of range not baking on bottom of oven. There are a variety of reasons for this, but one reason which does not appear to have been thought of is the length of the flue strip in the bottom flue. We have remedied just that difficulty sometimes by lengthening the flue strip and in other cases by shortening it. A patent has been granted to me under date March 13, 1894, No. 516,233, the specifications of which explain its operation. Would be glad to hear from Mr. Guelph and others.

Smoky Chimneys.

From J. R. S., *Stonington, Conn.*—Some years ago I built for myself a house, and soon after moving in it was found that the kitchen chimney smoked furiously when the wind came from a certain quarter. I had the top carried up several feet higher, but the evil was not remedied. Resort was then had to two or three ventilators, one of which proved to work very well. This continued for about a year, when the ventilator dropped from the chimney, and upon examination it appeared to be nearly eaten through from the effects of the products of combustion and atmospheric influences. I did not feel like expending more money upon patent ventilators, but after looking into the laws which govern the movement of air, I simply and effectually remedied the evil by contracting the mouth of the flue. This was done by inserting and cementing in the flue a short section of 6 inch Akron drain pipe. Since then I have had no trouble with gas and smoke. A number of my neighbors have suffered from these things, and are now adopting the plan which I have described. The reason for this simple and efficient remedy is plain enough. By the means employed the velocity of the current of air at the mouth of the chimney is made so great that unusual winds do not interfere with it.

Trouble With Pump.

From J. S., *Kansas City, Mo.*—In reply to "F. B. K.," who reports "Trouble with Pump" in *The Metal Worker*, March 24, his trouble is caused by air in the pipe, and if his valves are tight and he makes the change which he suggests he will have no further trouble.

Coloring Brass.

From A. B. F., *Brooklyn, N. Y.*—Please inform me in *The Metal Worker* how I can color a brass hand rail on a porch, black or dark color other than by painting, lacquering or oxidizing. It is an outside railing and cannot be taken down without a great deal of trouble and expense, hence my desire to color it in place with the least expense and delay.

Answer.—The following receipts from a receipt book may answer the purpose: Brush the object over with a solution of 1 part of platinum chloride in 5 of water. When dry rub it with a piece of flannel moistened with a drop of oil. The manipulations are to be repeated until the formation of a uniform dead black results. The railing must first be made clean, bright and free from grease or dirt. To obtain a brown color, add acetic acid to 11 drams of spirit of sal ammoniac until blue litmus paper dipped in it turns red. Then add 5½ drams of sal ammoniac and sufficient water to make 2.11 pints. With the fluid thus obtained, repeatedly moisten the surface, rubbing after each application, until the desired brown is obtained. A green is obtained by applying a solution prepared by dissolving 10 parts of copper in 20 of nitric acid, diluting the solution with 150 parts of vinegar and adding 5 parts of sal ammoniac. Allow the article to stand until a green coloration has made its appearance, brush with old linseed oil, then after a few days rub with a piece of soft flannel.

Galvanic Action.

From COPPER, *New York.*—We are invited to bid on the work for a building where the specifications call for the conductors and valleys to be of copper and the cornice which attaches to the copper gutter to be of galvanized iron. Will there be galvanic action between the copper and the galvanized iron that will eventually destroy the iron?

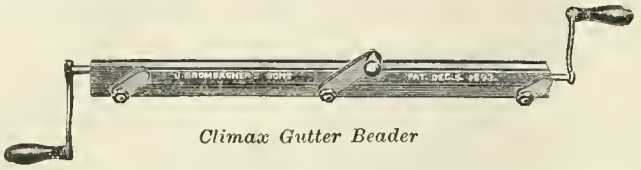
Answer.—That a galvanic action will take place is certain, and the length of time that the iron will last will depend on its endurance due to its thickness.

THE PLUMBERS of Lowell, Mass., are progressive. They have organized a base ball team, and are to give their fifth annual social on the eve of Lexington Day, April 19.

THOMAS M. ALLEN has opened a plumbing establishment at 719 Penn avenue, Wilkinsburg, Pa.

Climax Gutter Beader.

Jacob Brombacher's Sons, 30 Cliff street, New York, have brought out the Climax gutter beader, here shown. While similar to the familiar iron bottom gutter beader, it differs from the latter in that the two sides are not riveted or screwed permanently together. At each end is a wrought bolt riveted to the back portion. The front half travels on these rods or bolts. On the front section are cast two eccentrics

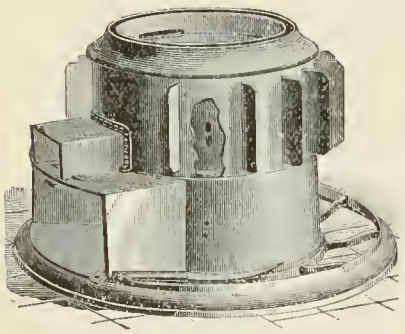


Climax Gutter Beader

with which the cam levers at either end articulate. The end levers are connected by a wrought bar about 1 x ⅛ inch in size. Throwing the center lever to the right closes the beader, while a movement to the left spreads it about ¼ inch larger than the work to be taken out. They can be furnished in any of the regular sizes from ⅝ to 1 inch rods, and from 20 inches long to 6 feet if necessary.

The New Idea Furnace.

In the accompanying illustrations we present views of a furnace which is being introduced to the trade under the name New Idea, by Schill Brothers, Crestline, Ohio. As placed upon the market, this heater embodies some improvements which have been added for 1894, and which the manufacturers expect will render it more popular than ever. Special reference is made to the



The New Idea Furnace.—Fig. 1.—View of Fire Pot.

fire pot used in the New Idea, the statement being made that it is double, consisting of an inner heavy cast iron pot, with a series of openings near the center and larger ones at the top. Surrounding the fire pot is a steel jacket forming an air heating chamber, into which air is admitted and raised to a high temperature before reaching the fire, thus facilitating combustion. In this way, the makers state, fully 90 per cent. of the gases and smoke heretofore wasted is consumed. By means of an opening and closing ring between the fire pot and steel jacket the draft can be so regulated as to burn any kind of fuel. Shaking this ring once or twice a week will prevent any ashes which may find their way into the air space between the fire pot and steel jacket from lodging at this point. The same ring when opened forms a dust flue. A good idea of this fire pot may be obtained from an inspection of Fig. 1. In Fig. 2 is shown the base of the furnace, together with grate and draft ring, the grate being shown dropped. The cut also presents a bottom end view of the drum, showing the inside flue. The grate employed is referred to by the manufacturers as being simple in construction and easy of management. By a simple device the center of the grate can be dropped and ashes and clinkers removed without disturbing the whole of the fire, or the entire grate can be shaken without opening any of the doors. The drum employed in this heater has been designed specially for the purpose and is so constructed, it is said, that every inch is available heating surface. It consists of an inner and outer heavy steel plate drum, the two being connected by steel wings drawn tightly together in such a way as to form air ducts and largely increasing the amount of heating surface. The latter, from the bottom of the ash pit to the top of the radiator, is in a straight line, there being no tubes, crooks or turns to prevent the free flow of large volumes of air. Another important feature of the drum is the diving flue, which extends to the center at the top of the drum, thus drawing the heat to that point and rendering all parts of uniform temperature. Every joint in the furnace is made with special asbestos wicking, which, it is claimed, makes a joint that will not leak. Expansion and contraction have been guarded against by making the lower drum head in sections, while the center of the upper drum head is raised. The outer rim of the upper drum head is also cut, thus guarding against cracking. The casing of the furnace is composed of one sheet of galvanized iron, one sheet of corrugated iron and one sheet of asbestos placed between the two, and all securely riveted together. The corrugated sheets are claimed to admit a free and uniform passage of air between the two, while the asbestos, being a non-conductor, prevents loss of heat by radiation into the cellar.

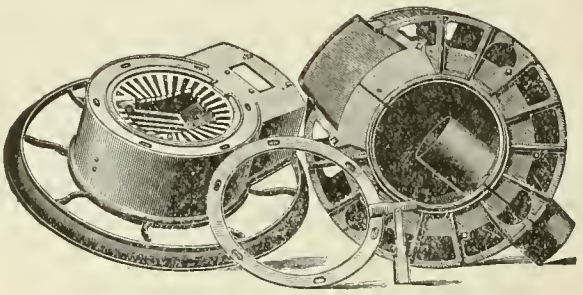


Fig. 2.—View of Base, with Grate and Draft Ring, the Grate Being Shown "Dropped."

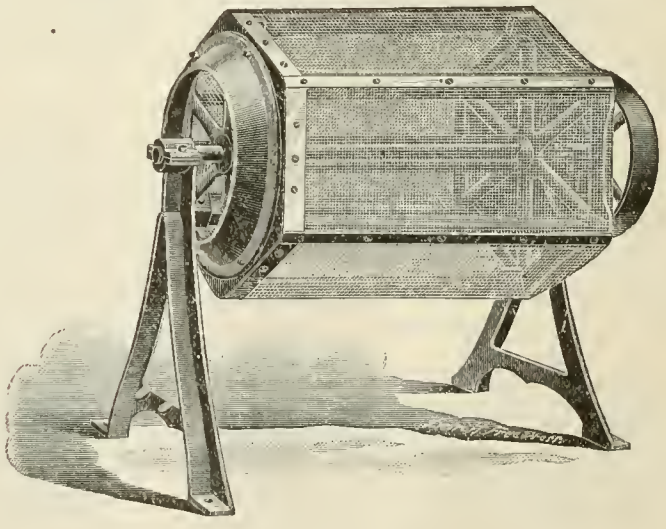
A New Sand Sifter.

The Detroit Foundry Equipment Company of Detroit, Mich., and Chicago, Ill., recently placed on the market the sand sifter here shown. It is of the revolving type, having a funnel at one end into which the sand is shoveled, and being slightly enlarged at the other end to allow the gravel and dirt to work itself out free of the sand. It differs from the ordinary radial machine, as it is provided with inside revolving radial screens of a larger mesh than the outside screen, and which thoroughly break up and pulverize the sand before it has an opportunity of falling through the outside screen. This type of screen has been in use for some time in several foundries in Detroit and elsewhere and has been found of special value in mixing up sand for facing, &c., also in mixing core sand. The screen is made so that it may be set on brackets or be suspended in hangers from above, and is suitably provided with pulley, &c., complete, ready to set up. It can be made of any length or fitted with any size screen suitable for the work to be performed.



A New Sand Sifter.

ROOFING AND CORNICE.

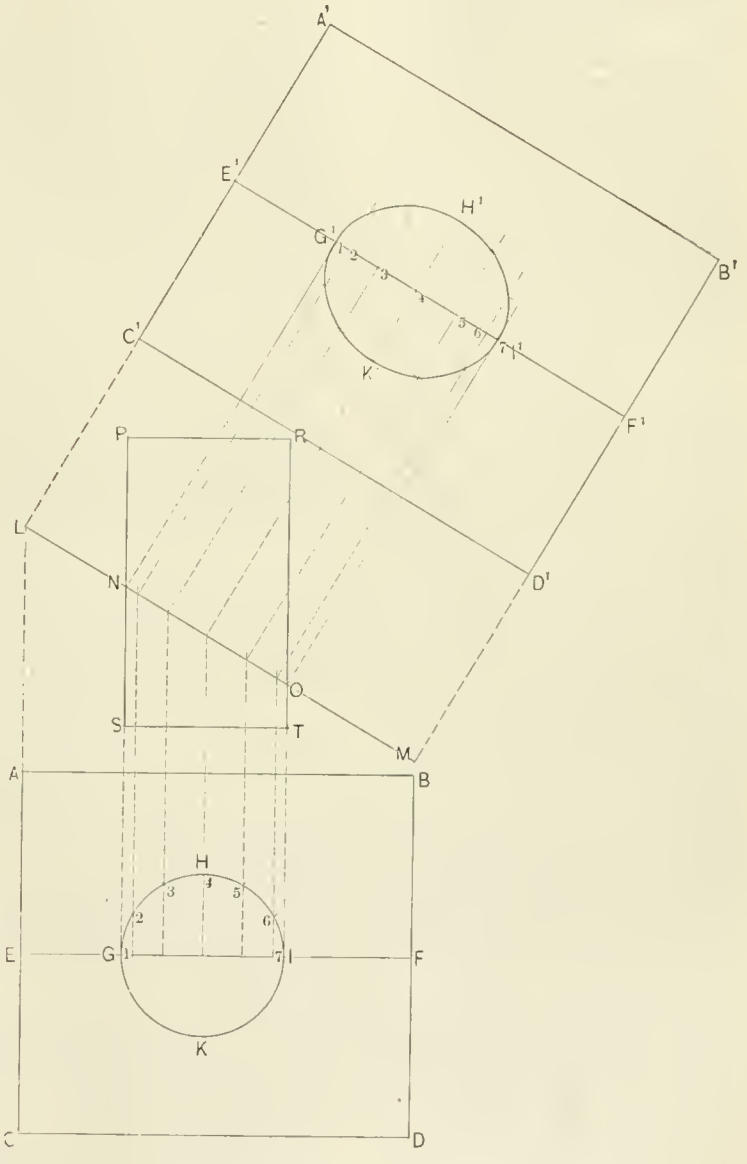
Repeal of a Sheet Metal Ordinance.

The cornice makers of Chicago have won a signal victory over their opponents. About a year since the City Council adopted an ordinance, against the protests of the cornice makers, prohibiting the use of sheet metal for bay windows and light shafts. Up to that time a heavy business had been done in furnishing galvanized iron and sheet copper bay windows on wooden frame work and corrugated iron light shafts with wooden backing. Several shops were fitted up with special machinery for turning out work of this character in the quantities demanded by their continually growing trade. It is claimed that the prohibitory ordinance was passed in the interest of the brick and terra cotta manufacturers. Be that as it may, the effect was to throw this business into their hands, and thousands of sheet metal workers in Chicago were without employment. In view of the fine prospects for building this spring, the cornice makers bestirred themselves, created a sentiment in their favor, demonstrated the fact that metal covered bay windows and light shafts were not combustible, and at length succeeded in inducing the City Council to remove the interdiction against their business. The only restriction made in the new ordinance is a limitation of metal covered windows to buildings not over four stories in hight.

Shape of Opening in an Inclined Roof.

From J. T., *Warren, Mass.*—I would like to see published in *The Metal Worker* a method for obtaining the shape of opening in an inclined roof through which a round pipe is to pass. The method should be such that the shape of opening can be described on a piece of sheet metal for a pipe of any size and for a roof of any inclination.

Answer.—Referring to the accompanying diagram, let L M represent the inclination of the roof and P R T S an elevation of the pipe passing through it. Then M O represents the length of the opening which is to be cut in the roof, the width of which will be the same as the diameter of the pipe. Let A B D C represent the plan of the roof as it would appear if viewed from a point directly above the pipe. Immediately in line with the pipe draw the profile G H I K, placing it in the center of the roof. Divide one-half of the profile in the usual manner and carry lines vertical to the line L M representing the pitch of the roof, and thence at right angles to it indefinitely. Carry points in the same manner from A and B. Draw C^1 D^1 parallel to L M and make C^1 A^1 equal to A C. Now draw A^1 B^1 parallel to C^1 D^1. Draw E^1 F^1 at a point corresponding to E F of the plan of the roof, crossing the lines drawn from the profile. From E^1 F^1 set off on each side on each of the measuring lines crossing it the width on corresponding lines measuring from E F in the plan to the profile. Through the points thus obtained draw a line, which will give the shape of the opening to be cut, as shown by G^1 H^1 I^1 K^1.



Shape of Opening in an Inclined Roof.

FLASHINGS.

The Columbia Roofing Company, Canton, Ohio, distribute their catalogue which is an enlarged edition of their former publications. The first notice is given to the Columbia steel roofing, illustrations showing the formation of the seam. Then comes the Columbia double seam roofing similarly illustrated; then pressed standing seam roofing, V-crimped roofing, and after that is noted corrugated iron. Then come beaded iron siding and steel ceiling, weather boards, &c. Considerable attention is given to flashings and ridgings. Brick siding is illustrated and iron shutters and doors. A number of handsome designs of crestings, cresting blocks and finials are shown. Hip caps, cornices and other goods are illustrated and briefly described. The pamphlet closes with an alphabetical index.

The eighteenth annual catalogue, reference book and price list of the Canton Steel Roofing Company, Canton, Ohio, is issued to the trade. In the beginning of the pamphlet the announcement is made that after one year's business with insufficient facilities, following the total destruction of their plant by fire, which frequently prevented the prompt filling of orders, the Canton Steel Roofing Company take pleasure in announcing that their works are now rebuilt and fully equipped, giv-

ing them better facilities than ever before. The catalogue is divided into two parts, the first beginning with illustrations and descriptions, &c., of the H. W. Smith Patent Folded Lock Standing Seam Steel Roofing. A number of roofing specialties, including paints, are noticed in this connection. Attention is given to corrugated sheets of various sorts, and illustrations show their application. Ridge rolls, flashings and cappings are illustrated; likewise crimped sheets, beaded iron, sheet steel, pressed brick, siding, shingles and doors and shutters of various kinds. The second part describes a full line of eave troughs and conductor pipes, eave trough hangers, conductor fasteners, ventilators, creatings, vanes, finials and other coated sheet metal goods, and attention is also directed to galvanized steel, terne and tin plate, copper, solder, sheet aluminum, &c. The catalogue, which closes with an alphabetical index, is a handsome publication of 100 pages bound in colored paper with stamped and gilded title.

The Illinois Roofing & Supply Company, 203 Lake street, Chicago, have secured the agency of Balm's extension ladders, and will keep a full stock on hand from which the trade can be supplied. These ladders are provided with automatic locks, which are claimed to be quick and certain in action, and have no springs to get out of order. The two section ladders are made in lengths of from 26 to 38 feet, and those of three sections from 42 to 50 feet in length.

The continuous roofing tin manufactured and placed on the market by Merchant & Co., Incorporated, of Philadelphia, and known by the brand name of Tandem, is reported as being very favorably received by the trade. The sheets, which are 96 inches long, are recommended as specially adapted to gutters and valleys. There being fewer seams and these being soldered on both sides during the process of coating, the liability to leaks is lessened. Moreover, the courses are absolutely straight. The advantages of this material, it is said, being widely appreciated by country tinners, to whom the saving of labor in soldering, time and material effected by its use is a great consideration. In this connection Messrs. Merchant's New York representative states that the sales of their continuous roofing tin have increased of late by leaps and bounds, in the New York and New England rural districts especially. Merchant's new patent Spanish metallic tiles are also reported as receiving the favorable notice of architects and roofers. They are made in tin or copper and the firm are now bringing a line of them out in enameled steel, which they believe will prove equally successful.

The American Roofing Company, St. Louis, Mo., and Cincinnati, Ohio, have just issued a little catalogue devoted to their gutter department. Diagrams are given showing the width and size of eave troughs, and general views are presented of the different styles. Attention is likewise directed to lap joint miters and eave trough hangers of different sorts, all being illustrated and priced. Corrugated conductor pipe, elbows and shoes, conductor heads are similarly noted, also hooks, strainers and cut offs. The pamphlet will be found especially serviceable, as all its contents relate to one general subject.

C. L. Rickert, 194 Clark street, Chicago, has the contract for the copper, slate and galvanized iron work for the Tulane University, New Orleans, La.

HEATING and PLUMBING.

NEW WORK AND CONTRACTS.

G. A. Hall has awarded the contract for the construction of his new block on College street, Burlington, Vt., to E. P. Libbey of West Randolph, and the contract for the plumbing and heating to the G. S. Blodgett Company.

Proposals for heating and ventilating the new school house of the town of Hadley, Mass., will be received up to April 7.

The town meeting of Lowell, Mass. recently voted an appropriation of $500 for heating School No. 8.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until April 12 for a low pressure steam heating and ventilating apparatus for the United States Court House and Post Office building at Martinsburg, W. Va. Drawings and specifications may be obtained from the Supervising Architect, Washington, or can be had from the superintendent at Martinsburg.

A. F. Waters, La Porte, Ind., has secured the contract for plumbing the new Lutheran school.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until April 13, for a low pressure steam heating and ventilating apparatus for the United States Post Office building at Staunton, Va. Drawings and specifications can be had from the Supervising Architect, Washington, or obtained from the superintendent, Staunton.

Edward A. Monroe, superintendent for John A. Scollay, 74 and 76 Myrtle avenue, Brooklyn, reports that their improved hot water heater has been installed in the residences of T. H. Howard, at Parkesville, and Hon. W. J. Kaiser, at Flatbush, L. I.

The town of Braintree, Mass., has appropriated $5000 for new heating, ventilating and sanitary arrangements in the Union and Pond school houses.

Professor Dodge's new residence at Argyle Park, Ill., is to be heated with one of the United States Heater Company's Hecla boilers.

T. C. Boyd, 42 Dearborn street, Chicago, is to move his plumbing establishment to the store and basement 38 of same street.

The Wells & Newton Company, 274 Dearborn street, Chicago, have the contract for the steam heating and plumbing in the residence of A. P. Brink, 1764 Sheridan Drive.

Peck Bros. & Company, 259 Wabash avenue, Chicago, are to furnish their plumbing specialties for the flat building of David Roberts, 202 South Clinton street, and for the residence of C. E. Gifford, 4637 Drexel Boulevard. P. Sanders & Son, 1314 Wabash avenue, do the plumbing.

The Board of Education of Salt Lake City, Utah, recently adopted a resolution authorizing the Building Committee to close a contract of $5725 with Heerch, Davis & Co., for a heating and ventilating plant in the Oquirra school.

Proposals will be received up to April 5 for heating the Primary School building at West Roxbury, Mass., and the Grammar School building at Dorchester.

The Fowler Radiator Company, 435 North Broad street, Philadelphia, Pa., have received a contract for radiators for the North Carolina School for Deaf and Dumb, calling for 10,000 feet of radiation, most of it being the Fowler semi-direct. The Brewster Hardware Company, Raleigh, N. C., are the contractors. The same firm have also recently shipped a carload of the direct and semi-direct radiators for another job, for which Allen & Cram, Raleigh, N. C., are the contractors.

F. Joseph Raehn & Co., Allegheny City, Pa., have installed hot water heating plants using the boilers of the Fuller & Warren Company for the following customers: Dr. Feree's residence and conservatory, the residences of J. Schomaker, John Carren and Mrs. S. B. Jenkins, and have heated the residence, store, office and workshop of Mr. Raehn.

The S. Wilkes Mfg. Company, 113–123 Clinton street, Chicago, are to install hot water heating plants in the residences of Dr. John Strouble and E. J. Tucker, Humboldt boulevard; also in the residence of John Burns, Austin, Ill.

A. C. Hickey, 69 Clinton street, Chicago, has the contract for the steam fitting and plumbing work in the warehouses of the Chicago Dock Company, at the foot of Taylor street.

Among the contracts recently taken for steam heating by the Theo. Jacobs Company, 72–74 Market street, Chicago, can be mentioned the following: Residence of A. F. Collins, 4930 Ellis avenue, and Joseph Redford's building, 36 Cottage Grove avenue.

Architect L. G. Halberg, 119 La Salle street, Chicago, is receiving figures for the construction of a three-story apartment house on St. James place, near Clark street, to be built by C. P. Lindquist. Steam heat is to be used.

Architect J. E. O. Pridmore, 123 La Salle street, Chicago, is receiving bids for the construction of the church to be built by the Seven-Day Adventists, at Forty-sixth street, near Wabash avenue. The building is to have a high pitched roof of slate and will be warmed by a furnace.

Architects Brompton & Lawson, Chicago, have designed for Homer C. Gross a store and apartment building, to be erected at Colorado and Albany avenues. It will be heated by steam.

Architects Murphy & Camp, Chicago, have prepared plans for an apartment house to be erected at 3641–3643 State street, to be five stories and basement high. The front will be constructed of pressed brick and copper.

F. Richter & Son, 382 to 400 Sixth street, Milwaukee, Wis., have been awarded the contract for heating and ventilating with fan system the Fifth Ward School House in that city for $7190; also the Sixth and Fourth Ward engine houses by steam, with the Richter boilers, for $530 and $430, respectively.

A decree has just been handed down by the United States Circuit Court of Appeals, Second Circuit, Judge Lacombe, in the appeal from the decision of the Circuit Court in the suit against James P. Allen for infringement of the Saunders patent dated January 31, 1882. The defense was assumed by the Armstrong Mfg. Company, Bridgeport, Conn., employers of James P. Allen. The decision of the Court of Appeals affirms the decree of the Circuit Court, which dismissed the complainant's bill.

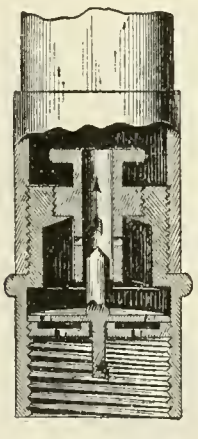
PLUMBING and GAS FITTING.

Lead Burning Class.

The progress made by the pupils in the lead burning class at the New York Trade School this year far surpasses that of any previous year. Nearly 40 pupils have qualified as excellent workmen under the system of teaching adopted by Instructor Thomas Walmsley. As a result another class has been formed from the members of the day plumbing class, and their instruction will begin April 2, to last one week. The skill acquired by the class during the term was gained in six lessons and some of the work that has been turned out has been of the most difficult character, and its appearance would be creditable to an expert. Among the work is a bottle trap with the vent attached that looks as if it was cast, a lead lined tank with all of the seams burned and waste pipe with a burned joint that has been made into a sharp quarter bend. This last operation gives a correct idea of the strength of a properly burned joint. The work that these young men have done with so short an experience reflects great credit to Instructor Walmsley as a teacher and conveys the impression that there is more mystery than difficulty in the art of lead burning. Some of the pupils are using their spare moments in making their own lead burning apparatus, the seams in the lead tanks requiring to be lead burned to stand the acids.

Economist Gas Governor.

The illustration herewith shows the Economist gas governor, patented February 6, 1894, by the New York Gas



Economist Gas Governor.

Saving Company, Decker Building, Union Square, New York, who are the manufacturers. It is a simple device intended for use in connection with ordinary gas burners to maintain an even consumption of gas and a steady flame under any pressure of gas. It may be used on any fixture and the old burner screwed on it. The illustration is more than twice the size of the actual governor, so that its construction and operation may be readily understood. It consists of a cylinder with a fixed diaphragm, a floating diaphragm and a hollow regulating screw. Both diaphragms are perforated, and an excessive pressure raises the float, which is guided by pins, until the projecting sides of the upper chamber partly cover the perforations, reducing the quantity of gas that can pass. At the same time the pin on the upper side of the float rises in the hollow screw to reduce the quantity of gas that can enter the opening in the side of it. When the hollow screw is properly set only a sufficient quantity of gas can pass through it to the burner to give a steady flame and the irregular, shooting flames due to an excess of pressure are avoided. The use of a burner that is rated 1 foot per hour less than the governor is set for is recommended so as to get a proper spread of flame. The company furnish instructions for setting and regulating the governors and have a duplicate contract by which they may be tested for one month without cost if they do not show a saving of 10 per cent.

TRAPS AND VENTS.

THE VACANCY in the Executive Committee of the National Association of Master Plumbers, caused by the death of James G. Weldon, has been filled by the election of J. J. Kennedy of Pittsburgh, Pa.

FROM PRESIDENT DANIEL G. FINNERTY of the National Association of Master Plumbers we learn that the differences existing between the association and the firm of J. Register & Sons of Baltimore, Md., have been satisfactorily adjusted.

ARTHUR SHEA, Rockland, Maine, has been improving the interior of his plumbing establishment and now has one of the finest offices on Main street.

JUDGE JAMES KEITH of the Circuit Court of Alexandria has granted a charter of incorporation to the United States Sanitary Company of Washington, who propose to do a general sanitary company business. Their capital stock is fixed at $50,000, divided into shares of $100 each. The officers are as follows: Benjamin Clark, Washington, D. C., president; J. W. Bartlett, secretary, and J. B. Kendall, treasurer. The above officers, with O. D. Bartlett of Washington and J. W. Taylor of Herndon, constitute the Board of Directors.

THE MASTER PLUMBERS' ASSOCIATION of Malden, Mass., recently met in the Theosophical rooms and listened to an address from National President Daniel G. Finnerty of Boston.

THE PLUMBING FIRM of Cannon & Paul at 219 Congress avenue, New Haven, Conn., have dissolved, the senior member withdrawing. Mr. Cannon will open a new establisment at 225 Congress avenue.

EDWARD ARMIT has purchased the stock of plumbers' material of H. C. Malo of Hohman street, Hammond, Ind. Mr. Malo has accepted a position with an Indianapolis house.

AN ORDINANCE has been adopted by the Atlanta, Ga., City Council providing for the examination and licensing of plumbers.

D. S. DUNAVAN will remove his plumbing business April 1 from Park avenue to East Front street, Plainfield, N. J.

SANDS & HOULE, who are about to open a plumbing shop in Biddeford, Maine, recently spent some time in Boston purchasing stock.

WM. GRITZMAHER is about to open a plumbing and steam fitting shop at Jamestown, S. D.

SUNKEL & HECKMAN have bought the Y. M. C. A. building at Zanesville, Ohio, and will use it as a plumbing establishment.

THE BROOKLYN HOUSE of the Henry McShane Mfg. Company, at 50 and 52 Myrtle avenue, have a line of plumbers' goods that comprises everything required for a modern system of plumbing, and are having demands made upon it as the season begins to open.

THROUGH the failure of the authorities of Leominster, Mass., to comply with the State plumbing law, the plumbers of that city are in a peculiar dilemma. Plumbers from surrounding towns can come there and do all the work they can get, but Leominster plumbers, not having been examined, licensed and registered according to law, cannot work in the outside towns.

WILLIAM S. COSTA, formerly foreman for L. C. Yaeger, Tallahassee, Fla., together with John M. Chase from New York, have begun business under the firm name of Costa & Chase, as plumbers, tinners, gas and steam fitters and roofers, at Tallahassee, Fla.

"JUST A FEW WORDS" is the title of a pretty catalogue sent out by the Toronto Steel Clad Bath & Metal Company, Limited, relating to the steel clad baths. The few words are addressed to architects and touch upon the excellences of the steel clad bath.

THE MASTER PLUMBERS' ASSOCIATION of Passaic County, N. J., with headquarters at Paterson and a membership of 37, have affiliated with the National Association of Master Plumbers.

C. H. REVERCOMB has purchased the plumbing and steam fitting business of W. H. Smith, Winnipeg, Man.

DUNCAN MCTAVISH has purchased the gas fitting and plumbing establishment of Geo. McLane, at Racine, Wis.

THE FIRM of Ryan & Surrell, plumbers, composed of Oscar Ryan and Howard Surrell, have just opened a shop at Fort Wayne, Ind.

"PLUMBING, OLD AND NEW," is the title of a 16-page pamphlet being sent to prospective customers by Boyd & Schnaier, 347 Columbus avenue, New York. The pamphlet has a yellow cover with a scroll design, into which a cluster of tools is worked. It is illustrated with half tone engravings of old and new work and also shows a corner of their sample rooms. Two pages are specially devoted to explaining the

character of their work, and it is mentioned that they import sanitary earthenware. The testing of plumbing work with a sanitary smoke machine is made a specialty.

THE Detroit, Mich., board of plumbing examiners, J. Meathe, H. McDonald and S. Dickson, will meet hereafter every Friday evening to examine applicants for licenses as master or journeymen plumbers. In Detroit there are about 165 master plumbers and 250 journeymen. Of this number but 215 have registered.

THE BOARD OF EXAMINERS for plumbers' licenses at West Newton, Mass., consists of Dr. F. G. Curtis, Geo. H. Elder and W. H. French. It has organized with Dr. Curtis as chairman and Mr. Brimblecom as clerk, and will hold examinations for applicants for licenses on the last Wednesday of each month.

AN ORDINANCE has been passed by the Council of Aurora, Ill., providing for an inspector of buildings and plumbing, to be appointed May 1.

HUGH MCCOLLUM, a plumber, of Cincinnati, Ohio, recently died at the age of 62 years. He was a man of superior executive ability and rendered excellent service to the Ohio Mechanics' Institute, of which he was a director and treasurer for more than 20 years. He was also an active worker in the Cincinnati Industrial Expositions.

DR. W. H. SHAFLER, North Manchester, Ind., and J. W. Domer will open up a plumbing establishment there this spring.

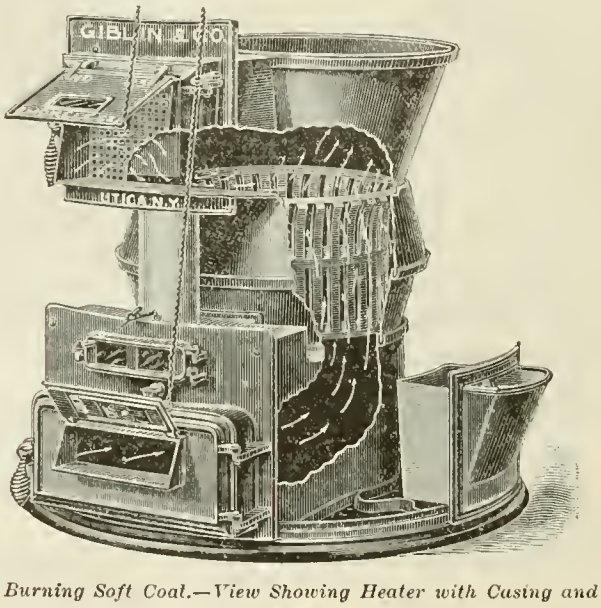
THE FIRM of Dunbar & LaChapelle, plumbers, have been dissolved and the business will be continued by Alexander P. LaChapelle at 178 High street, West Medford, Mass.

A FIRE at Pawtucket, R. I., damaged the plumbing establishment of Taylor & Co. to the extent of $5000; covered by insurance.

PLUMBER J. J. HOULIHAN has removed to one of the basement stores in the Whipple Freeman Block, Brockton, Mass.

Furnace for Burning Soft Coal.

A furnace which is said to be so constructed as to successfully burn soft coal as a fuel has recently been introduced to the trade by Giblin & Co. of Utica, N. Y. It represents the results of careful investigation and experience in connection with the use of the fuel named, and aside from the soft coal apparatus is like the company's well-known Standard furnace. One of the special features incorporated in this heater is the sectional fire pot, in which the coal is held suspended in such a way that it is surrounded at the sides and bottom by the air passing through the ash pit, allowing all parts of the fire to be reached by the air for the purpose of promoting combustion. The engraving which we present herewith is a view of the furnace with the casing and radiators removed, while a portion of the side is broken away, showing the position of the fire pot and the course of the air currents entering through the combination door and ash pit. The combination door is so devised as to admit just the quantity of air required by the fire in order to insure the best results. When the door is lifted the air is admitted through perforations, and striking the solid plate back of the perforated one, causes the air to travel in a downward direction, becoming heated in its progress and finally enters the combustion chamber. This air while warm is yet cooler than the air in the combustion chamber, which causes it to take a course along the bottom of the mouthpiece until it meets the ascending gases and is drawn in and united with them. The makers state that by the use of this combination door and sectional fire pot the fuel is suspended in a body of warm air, and whatever oxygen is required for combustion is drawn from it. It is also stated that the parts of the soft coal burning apparatus can be removed and replaced through the feed door without disturbing the other parts of the heater. In this apparatus, it is claimed, there are no joints in the hot air chamber through which gas and smoke may escape. Reference is made to the durability of the fire pot, and to the fact that the four-dome radiator, which rests directly upon the section of the heater shown in the engraving, is made in one casting without any joints, its peculiar construction giving practically a vertical interior surface. By this arrangement, it is pointed out, dust, soot and ashes have no place to rest and must necessarily fall back into the fire pot, making the furnace practically self cleaning. The manufacturers refer to the large smoke outlet as providing ample draft, and say that the proportions of the furnace are such as to give satisfactory results in operation.



Furnace for Burning Soft Coal.—View Showing Heater with Casing and Radiator Removed.

SCRAP.

GEORGE W. JAQUES, late a member of the tin plate and metal firm of A. A. Thomson & Co., New York, has embarked in business for himself as a manufacturer of American tin and terne plates. Mr. Jaques is widely known in the trade, with which he has had a connection of 30 years' standing, and is thoroughly acquainted with the manufacture of tin plates. The Jaques tinning machine, of which an illustrated description was recently given in *The Metal Worker*, was designed and patented by him; and it is this machine that is being operated in Mr. Jaques' new works. These works are on Thirteenth avenue between Twentieth and Twenty-first streets, New York City. They are well situated and equipped with all the most modern facilities for the production of high grade plates. Two pots are at present installed and at work, having started up last week. Two more will shortly be added. The first output was composed of bright plates, specimens of which were submitted to the leading tin plate houses of the city, eliciting their warm commendation. The Jaques tinning pots, which were put in practical operation here for the first time, have been found to work entirely satisfactorily. Mr. Jaques is a firm believer in the future of the American tin plate industry, tariff or no tariff, and has made preparations for a long tenancy of his present quarters.

ONE of the largest cab companies in Paris is using tin plate for the bodies of the vehicles. Experiments are now being made with aluminum for this purpose, in order to still further decrease the weight.

THE UNITED STATES IRON & TIN PLATE MFG. COMPANY, Demmler, Pa., have recently placed a contract for a second Mesta patent pickling machine with the Leechburg Foundry & Machine Company of Pittsburgh. The first Mesta machine in operation at the above plant has been running for about two years, and has been pickling from 40 to 45 tons of sheets per day. The Leechburg Foundry & Machine Company have received orders for three of these machines during the last two weeks.

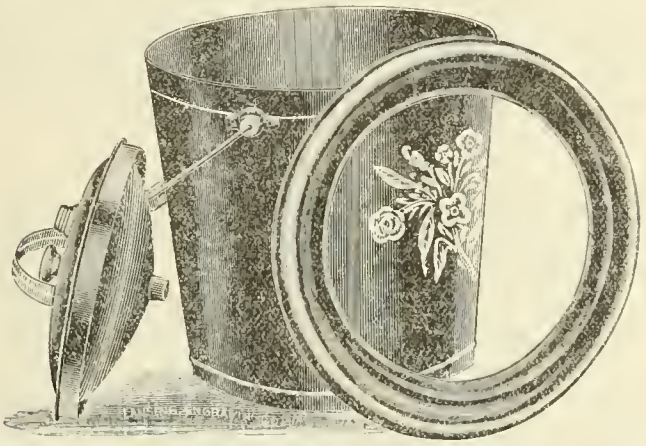
THE FALLING OFF in the consumption of pig tin in the United States during the last few months has been quite remarkable. The total consumption is calculated at 2400 tons since January 1, as compared with 4300 tons in the corresponding period of 1893. The reserve stock in hand is also extraordinarily low, being less than 1200 tons in New York, Boston and Philadelphia, of which about 1000 tons are held in bond.

MERRY & CLARK, successors to John Merry & Co., 535-547 West Fifteenth street, New York, mention that their special heavily coated brand of roofing plates—Merry's Old Method—is meeting with great approval from the trade. As an illustration of the sterling quality of these plates, it is stated that a roof covered with them was put on in Harlem in August of last year and remained unprotected by paint until a week or two ago. The plates were found to have stood the trying winter weather remarkably well. They had not rusted, and in every respect remained in a perfectly sound condition.

THE RETAIL STORE.

Commode Deodorizer and Slop Jar.

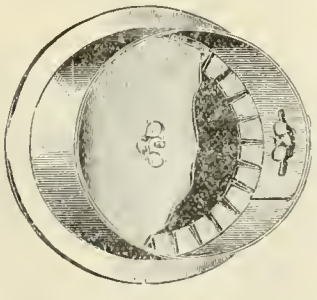
The Folding Bath Tub Company, Marshall, Mich., are putting on the market a combination commode deodorizer and slop jar, an illustration of which is shown in the accompanying engraving, which shows the separate parts of the commode, it having the appearance of a slop jar when the parts are placed together. It is an article specially intended for hospitals and sick-rooms, and particular emphasis is laid upon the fact that it is an instant deodorizer. The body and seat are made of flax fiber, the cover being of metal, having a hollow chamber which contains the deodorizer, and by opening a valve a portion of the disinfectant is allowed to pass into the body of the commode. When not in use as a commode it takes the place of a slop jar, being described as light, durable and non-adhesive and easily cleaned.



Separate Parts of Commode and Slop Jar.

Adjustable Flue Stop.

The accompanying illustration shows an adjustable flue stop that is manufactured by Foster & Keach, Table Grove, Ill. The stop can be made to fit any pipe opening; and when adjusted cannot, it is claimed, become loose or be blown out. It further provides a double protection against smoke and soot, and the inner plate protects the outer part from becoming heated and thereby defaced. The stop is described as substantially made and firm in position after adjustment.



Adjustable Flue Stop.

Fifty Years a Merchant.

On March 1 William H. Barlow, Hardware merchant, of Sing Sing, N. Y., completed the fiftieth year of his connection with that business. To signalize the event Mr. Barlow gave a supper in the evening to his employees and a few invited guests. On behalf of the employees Mr. Barlow was presented with an elegant gold headed ebony cane, his initials being engraved on the handle. During the evening Mr. Barlow made an interesting address, in the course of which he narrated the history of the business. From this address we take pleasure in making the following extracts:

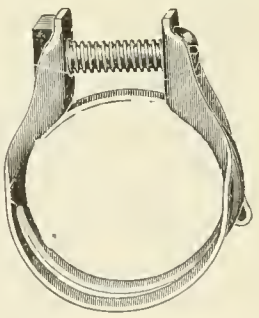
One man in the shop was able to make all the Tinware sold and do all the work outside, with the help of a boy. I went in the shop to learn the trade, but I was the boy of all work. I opened and closed the store, was clerk, helper in the shop and stove blacker. For four years I did this kind of work for the munificent salary of $30 a year and board. In 1852 I bought out Mr. Jarvis' interest, when the firm became J. Barlow & Son.

What a difference in the trade today in this place compared to 50 years ago! Then two tin shops with one man each were able to do all the work and make all the Tinware sold. There was no machinery used for making Tinware at that time. Now we have in this place seven tin shops. There was no plumbing, gas or steam fitting done then, as there was no one competent to do it, and there were no hot air heaters used; mostly wood Stoves were in use. Now we have men competent to do any kind of heater or tin work, also plumbing and steam fitting.

What a change in the Hardware trade since 1844! Then all the Hardware sold was imported, excepting Cut Nails; all Wrought and Horseshoe Nails were imported. All the wholesale Hardware stores in New York City were below Wall street, in Pearl. The first American Hardware I remember being made in this country was Door Locks, which were made in the prison here. All the Carpenters' Tools used were of foreign make, now the United States send immense quantities of Hardware to England, and in Saws and Edge Tools we can beat the world.

Sherman's Hose Clamp.

H. B. Sherman, Battle Creek, Mich., is offering an improved hose clamp, as herewith shown. It is stamped in one piece from sheet brass. The strip that is cut out from the lower part of the band is turned up under the screw to give an even grip. The manufacturer claims that the band remains always tight upon the hose; that it will not rust; that it is strong; that it can be easily taken off, and that it is as cheap as a wire band. The clamp is made in ½, ¾ and 1 inch sizes.



Sherman's Hose Clamp.

MEMORANDA.

W. T. Hoffman & Co., who began business in 1883 with a small tin shop, have been gradually enlarging their premises until they occupy two stories of a building 38 x 70 feet, they having lately doubled their facilities. They carry a full line of hardware, stoves and ranges, glass, paints, oils, varnishes and house furnishing goods. Their building, which they occupy, was built in 1888 of stone and brick.

We learn from George Rome & Co., Mansfield, Chartiers P. O., Pa., that their town name has been changed to Carnegie, to which address all mail matter should hereafter be sent.

William I. Davenport, son of the late William Davenport, died March 21 at Albany, N. Y., aged 30 years. His father conducted a stove store on North Broadway for many years and was succeeded by his son, who carried on the business with success up to within a short time of his death. The deceased was a director of the Albany Stove Company, and at one time treasurer of the Commercial Union Co-Operative Bank. He also held the position of financial secretary of the Catholic Union.

John G. McBride, about April 15, will open business at Missoula, Mon., with a complete line of stoves, tinware, house furnishing goods and plumbing. He requests dealers to send him catalogues in these lines.

STEAM AND HOT WATER.

Connecting Two or More Boilers Together.

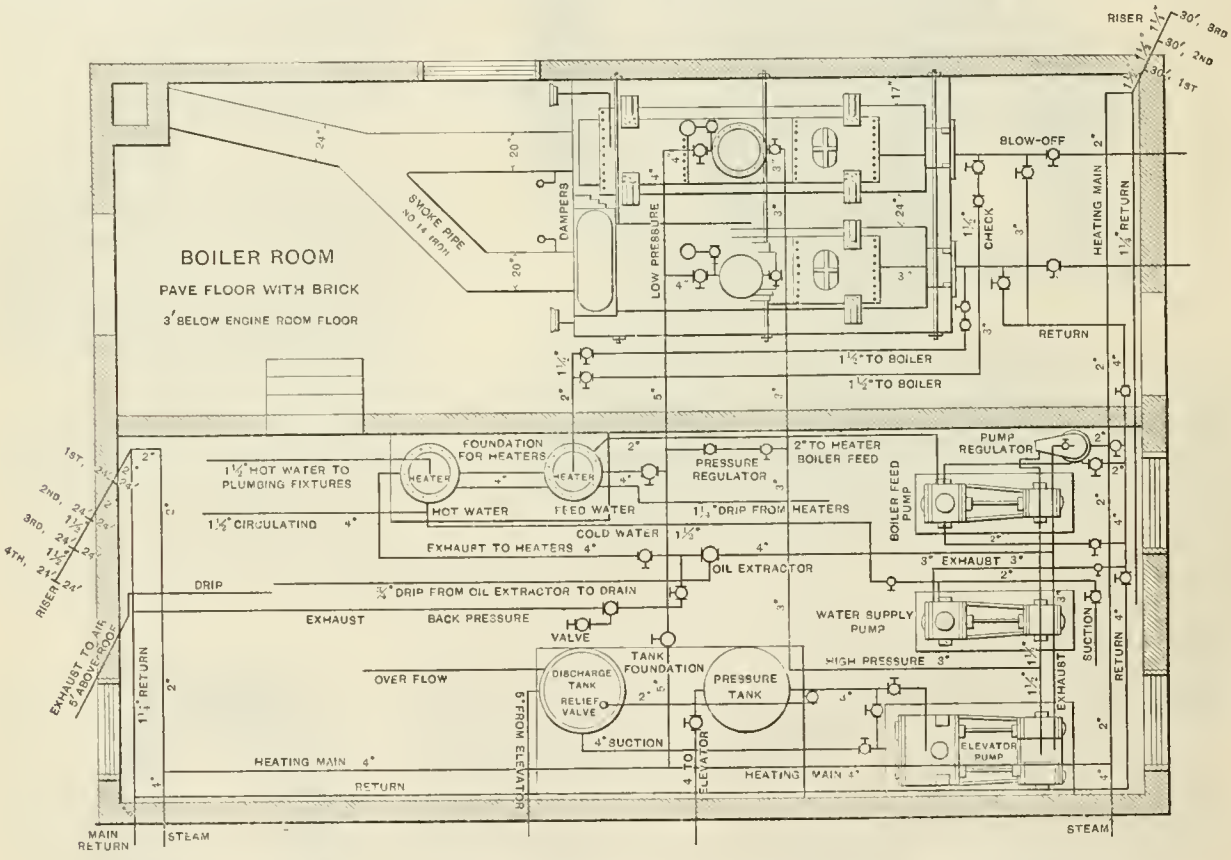
BY HELIOS.

The steam fitter is often called upon in erecting large steam plants, where there are two or more boilers used, to manage the piping so that one or any number of boilers can be used at a time to warm the building. In setting the boilers the water line must be at one level for all the boilers if they are to work on the return gravity system. The steam connections must be taken from the highest part of the boiler and connect into a large main steam pipe. The return pipe to the boilers must be large and connect into one large return main.

For an example of the size of pipe necessary I will give the size to use on a pair of boilers having 36-inch diameter grates. From each boiler connect a 4 inch steam pipe into a 5 inch main steam pipe, and connect a 3-inch return pipe from each boiler into a 4-inch main return pipe. Place angle or gate valves in the steam and return pipes, to shut when the boiler is not in operation. Do not place check valves in the return pipes. With connections made like the above explanation there will be no trouble in the working of the apparatus; the water line will always stand at the same level in the boilers, and it will keep at the same level if there is a very strong fire in one boiler and a very light one in the other. If the main steam and return connecting pipes are large enough the pressure in the boilers will equalize and the water will stand at one hight in both boilers. Boilers of any size or any number can be connected together as the above connections are made and will work perfectly if the pipe connections are of the right size to equalize the pressure on all the boilers.

High and Low Pressure Boiler Connections.

In a building that is warmed by steam having a large amount of radiation, which will require two or more boilers to do the heating, and high pressure is also used for power, the boilers can be connected together so that all of them can be run on low pressure or any of them on high pressure. Take a pipe from the top of each boiler and place a tee on the end, the openings looking from the front to the rear; place a valve on each side of the tee. Connect from the valves on the rear into a large steam main for low pressure, and from the valves in front into a steam main for high pressure. Make all the connections to the boilers as if they were only to be used for low pressure, as explained in previous articles (connecting two or more boilers together), only place a tee in the return connection to the boilers between the valve and the boiler for pump connection when the boiler is used for high pressure. Connect the high and low pressure steam pipes together and place in this connection a pressure reducing valve, so that if any of the boilers are used for high pressure the boiler can be worked to its full power, and all steam not used for power can be used for heating. All the exhaust steam from the engine or other power can be used to warm the building by connecting the exhaust to the low pressure main. Place in the exhaust pipe from the engine an oil extractor to remove all the cylinder oil from the exhaust steam. For supplying water to the high pressure boiler, place a steam pump and connect the suction to the main steam pipe. Run the discharge pipe from pump and connect into the tee in return pipe to the boiler. Place in the water supply pipe at boiler a check and valve. The exhaust from the pump can be connected into the exhaust pipe from the engine. By this arrangement any of the boilers can be used for high or low pressure and all of the exhaust steam can be used for heating.



Connecting Two or More Boilers Together.—Fig. 1.—Plan of Boiler and Engine Room for a Hotel.

Plan of Boiler and Engine Room for a Hotel.

The plant shown in the illustration is one that has been erected in a large hotel in the South. It shows high and low pressure boiler connections and exhaust steam connections, also low pressure steam heating. Two 50 horse-power return flue tubular boilers were used for the heating and power. High pressure steam was supplied to a duplex

steam pump to operate the elevator, a single acting steam pump for the water supply of the building and a single acting steam pump for feeding the boilers. The boilers are connected up so that any one can be run on high or low pressure, or they can be run on high or low pressure together. When one boiler is used on high pressure the exhaust is used to warm the building, with steam direct from the boiler to supply all the steam necessary for the heating if there is not enough exhaust steam. In cold weather the two boilers are run on high pressure from 6 a.m. to 12 p.m., and all through the night they are used on low pressure. When used on high pressure the condensation is returned by a steam pump. When on low pressure the condensation returns by gravity. All the exhaust steam passes through two feed water heaters; one for supplying hot water to the kitchen, laundry and plumbing fixtures, the other for heating the feed water for the boilers. Fig. 2 shows heater connections. All drips from heaters and exhaust pipes are carried back into the main return pipe from radiation and connected into the return between the boiler and valve in main return. Fig. 1 shows all steam, water, drip and return connections, also elevator connections to pressure tank, from pressure tank to elevator, and discnarge from elevator to discharge tank, also from discharge tank to pump.

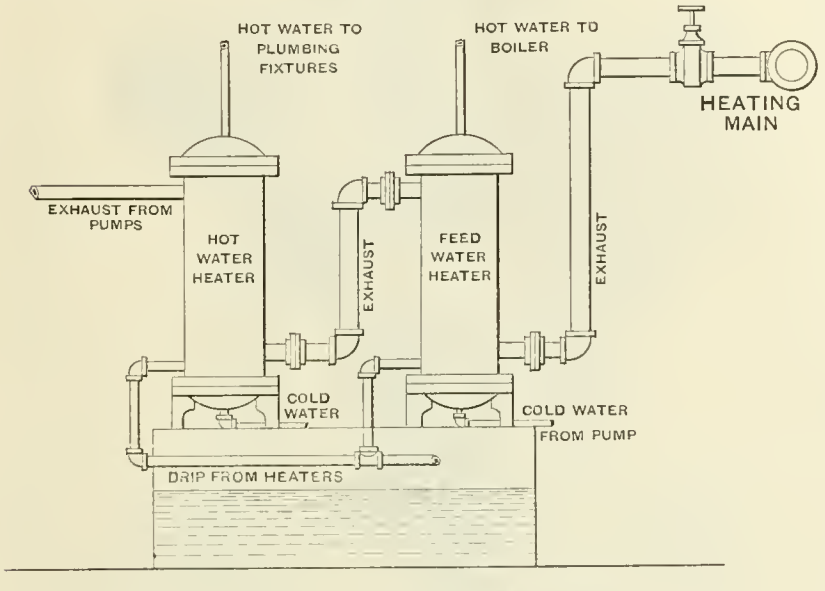


Fig. 2.—Elevations of Heater Connections.

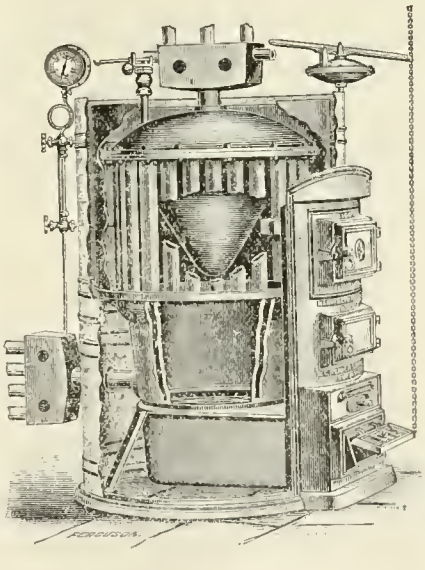
Location of Expansion Tank.

From M. K., *Bound Brook, N. J.*— A discussion of the following questions in *The Metal Worker* would be interesting to many of its readers. Should the expansion tank be placed on the flow or return pipe in a hot water heating system? Why is the expansion tank usually placed on the return?

Note.—Here is an invitation for our readers to give their opinions on expansion tanks. It is claimed by some that the expansion tank should be placed on the return and preferably at the boiler. Where a distant radiator is near the highest point the expansion tank is by some connected with the return from the radiator. It has been said that when the expansion tank is placed on the flow pipe it is not only filled with hot water and considerable heat lost, but under heavy firing at the boiler it overflowa and sometimes the water is blown out by the steam. The same authorities claim that when connected with the return this is prevented and that the heat which would be lost is utilized. Others claim that when connected with the return it is necessary to run a small pipe from the flow main to the expansion tank, if located in a cold place, to keep up a circulation and prevent it from freezing. These opinions from various authorities may call up corroborative experience from our readers.

The Henderson Steam or Hot Water Heating Boiler.

In the accompanying illustration we present a broken view of a steam boiler for house heating purposes made by J. C. Henderson, Troy, N. Y. The same boiler is also adapted to heating with hot water. The boiler, it will be noticed, consists of an annular water space forming the fire pot, of cast iron, also another water space made in a conical shape, likewise of cast iron, and supported above the fire. Between these two sections is a circular row of 2 inch wrought iron tubes expanded into the fire pot section and the cast boiler above. Particular attention is directed to the way the surface is arranged as giving exceptionally efficient service. The flames and hot gases impinge on the conical surface, and at the same time vertical circulation is provided for by means of the connecting tubes. From the top of the boiler the flow is taken, while the return is carried to the header and from thence into the bottom of the fire pot section. The boilers are made in five sizes, the fire pot in the smallest sizes being 14 inches deep, and in the larger sizes 22 inches deep. A special point is made of the deep fire pots, the manufacturer stating that they will maintain a more steady and uniform fire with less care and attention. The boilers have dumping and shaking grate, and are incased as shown in the cut.



Broken View of Henderson Steam Boiler.

HEATING NOTES.

C. S. Graves, who is well known to the steam and hot water trade in the vicinity of New York, is now one of the representatives of the American Boiler Company, 94 Centre street, New York.

Phillips, Doup & Co., Pearl and water streets, Brooklyn, have had a steady trade in their steam heating boilers, and report that general satisfaction has followed their installation wherever used.

John A. Scollay, 74 and 76 Myrtle avenue, Brooklyn, has remodeled his construction plant for the erection of heating apparatus and put in a line of pipe cutting machinery, run by power, and is abreast of the times with this capacity to handle large contracts readily. The advance was necessary to properly meet the requirements of the growth of business in manufacturing and selling the Scollay hot water heaters.

The James W. Birkett Mfg. Company, 51 and 53 Jay street, Brooklyn, find a combination of steam and hot air popular with their trade and have used the Economy heaters in a number of contracts.

Barber & Ross, Eleventh and G streets, N. W., Washington, D. C., have added a hot water and steam heating department to their business and have engaged W. H. Pennell, well-known to the trade, as superintendent of the new department, which will have a corps of competent workmen under his direction.

The United States Heater Company, Detroit, Mich., issue circulars relating to their well-known Hecla steam heater. One small circular shows a general view of the heater, with table of sizes and some few important particulars. A larger circular gives fuller information, together with several illustrations.

Major H. E. Light, who has been assisting the Eureka Heating and Ventilating Company of Saginaw, Mich., in installing some large plants, is making a visit in the East before entering the spring and summer campaign.

In *The Metal Worker* of March 17, page 35, we referred to the fact that the Pittsburgh Heating Supply Com-

pany's business at Greensburg and McKeesport, Pa., had been purchased by H. Clymer Painter and S. J. Sloan, who will continue the business at the former place under the name of Painter & Sloan, and at McKeesport as Sloan & Painter. We made a mistake in referring to the business of the new firm, who will be engaged as dealers and contractors for hot water, steam and hot air apparatus, tile work of all kinds, &c.

Vice president A. T. Henderson of the United States Heater Company, manufacturers of Capitol, Hecla and Mascot heaters, Detroit, Mich., was in New York last week looking for a location for a branch office. Mr. Henderson wishes to arrange for desk and sample room in connection with some other concern, preferably in the plumbing supply business, or with some dealer in fittings in the Centre street district. Mr. Henderson will be glad to hear from any one having space to rent for this purpose in the neighborhood mentioned.

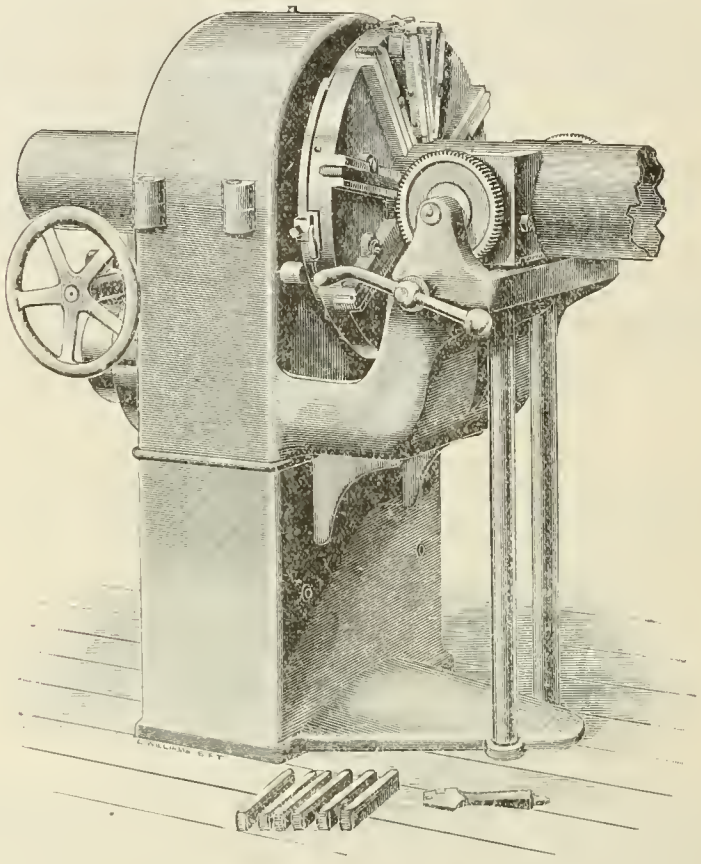
C. M. Wolley, secretary of the American Radiator Company, took passage March 21 on the steamer "Majestic" for a two months' trip to Europe.

A. E. Appleyard, Boston, Mass., is the patentee of an electric heating apparatus, one half interest in which is assigned to H. F. Folsom. The invention relates to an apparatus adapted for heating water with a view to making it circulate through radiators and the usual piping system.

We are in receipt of some neat little pamphlets from the Richmond Stove Company, Norwich, Conn., descriptive of their well-known line of steam and hot water heaters. These pamphlets, bound in colored paper, are issued in the names of different dealers handling the Richmond heaters. One of them, descriptive of the Rex heater, carries the name of L. M. Rumsey Mfg. Company, 810 North Second street, St. Louis, Mo.; another, referring to the Richmond heaters, is issued in the interests of W. R. Park & Son, 19 Court street, Taunton, Mass.; a third Richmond heater catalogue carries the name of Canfield Stove Company, Rondout, N.Y.; while a fourth pamphlet relating to the Richmond boilers has on the front cover the name of Edward E. Parker, 8 Middle street, Woburn, Mass. All of these pamphlets describe the heaters mentioned with neat illustrations and table of sizes, and in addition there are several pages of testimonial letters at the end of each pamphlet, the letters coming from persons in the district of the firm whose name appears on the cover. The Richmond Stove Company issue similar pamphlets to the firms handling their goods when the latter furnish them with testimonial letters for publication.

Threading and Cutting Off Machine.

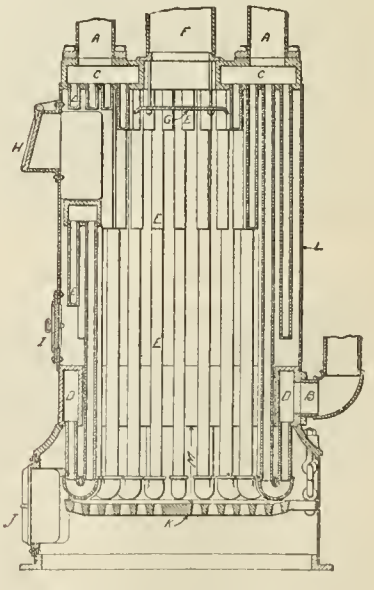
The illustration herewith shows a pipe threading and cutting off machine made by the Armstrong Mfg. Company, Bridgeport, Conn., with New York office at 139 Centre street. The merit of the machine, it is said, has been developed by experiment, and it possesses the advantages of both simplicity and compactness. It is made in several styles and sizes, adapted for either hand or power, and adjustable to variations in fittings. The machines are made to cut off and thread pipe from 1 to 6 inches in diameter, and are arranged for the pipe to be taken from them without removing the dies by a simple movement which effects an important saving of time and labor. All of the gears and working parts are incased in an oil chamber, which keeps the bearings lubricated and prevents the entrance of iron chips or dirt. From two and a half to four minutes are occupied in threading a pipe, according to its size. The No. 1½ machine, which works pipe up to 4 inches, weighs about 700 pounds, and has a countershaft speed when used with power of 325 revolutions. The No. 3 machine works 6-inch pipe and weighs 1200 pounds. The cutting and threading tools are made of the best material and are interchangeable. The machines are always fitted with right hand dies unless otherwise ordered, when dies for cutting left threads can be furnished. The large machine can be operated by hand power when desired, the speed depending on the activity of the man at the crank.



Threading and Cutting Off Machine.

The Windsor Hot Water Heater.

The Windsor Heater Company, Galena, Ill., manufacture the Windsor hot water heater, a sectional view of which is shown in the accompanying engraving. The heating surface, it will be noted, consists of an upper chamber and a lower water ring, connected by pipes with return bends immediately above the grate. This gives a very extended and efficient fire surface. The manufacturers point out particularly the fact that every joint is made iron to iron without packing or bolts. The boiler is surrounded by a substantial steel sheel which can be easily removed. The return water enters the lower annular water space, whence it is distributed around the heater and then conveyed through a large number of vertical pipes to the upper water space, all the time in contact with the fire. The heaters are made for burning hard or soft coal and will, it is claimed, burn any kind of fuel commonly used for heating purposes. The surfaces being vertical, it is mentioned that cleaning is not needed, except the ash pit, which is very large and deep. The Windsor heaters are made in ten sizes with outside diameter from 22 to 42 inches; fire pot 13 to 30 inches diameter, adapted to supply from 300 to 3300 square feet of radiation.



Sectional View of Windsor Hot Water Heater.

STOVE TRADE NOTES.

National Association of Stove Manufacturers.

The following announcement has been issued under date of March 24 from the office of Secretary D. M. Thomas:

The twenty-third annual meeting of the above association will be held at the Auditorium Hotel, Chicago, on Wednesday, May 2 next, at 10.30 a.m. Arrangements have been made with the hotel managers for a rebate of 50 cents per day from their usual charges for rooms with meals, which are from $4 per day upward. Rooms without meals may be had at the usual rates of $2 per day and upward. Accommodations can be reserved by application to the manager, stating requirements. It is designed that the discussion of subjects connected with the production of stoves shall be a prominent feature of this meeting, and the president earnestly desires that every stove foundry manager will be in attendance, as well as those gentlemen connected with the distributive department who are usually present.

The preparation of certain papers has been arranged for, among which are the following:

The Principles of Design as Applied to the Ornamentation of Cast Iron, with Especial Reference to Stoves.

Pattern Construction, Including Follow Boarding.

Foundry Management.

The Relations Between Employer and Employed.

The Stove Business of the European Continent.

The Education and Production of Efficient Workmen.

Cleaning Castings.

Can Profit Sharing with Employees be Used to Advantage by Stove Manufacturers?

The Advantages or Disadvantages of Interchange of Information and Experience Between Stove Manufacturers.

It is believed that they will contain valuable information and the comments following them be most instructive. Other papers are requested—indeed, contributions upon any of the various operations of a stove foundry will be welcome. It has been customary to invite to our annual meeting stove manufacturers who are not members of the association. A similar invitation is now extended, and the president cordially requests every firm receiving this notice to be with us and take part in the discussion of such subjects as are of general interest and to present their views upon topics connected with the production of stoves by means of original papers or essays. Those not officers of corporations nor members of firms should furnish credentials from their principals addressed to me. Firms who expect to be represented will kindly fill out and return the inclosed blank.

Secretary Thomas has also issued under the same date a letter to the effect that the ninth annual meeting of the Stove Founders' National Defense Association will be held at the Auditorium Hotel, Chicago, on Tuesday afternoon, May 1 next, at 2 o'clock sharp.

Cupola Management.*—IX.

BY DR. EDWARD KIRK.

Bod Sticks.

Two kinds of bod sticks are used for stopping in a cupola. They are the wood stick and the combination wood and iron stick. The wood sticks are made eight square or round from 1½ to 2 inches diameter and from 5 to 10 feet long. They are made of both hard and soft wood and about an equal number made of each wood, as some prefer one and some the other. When stopping in the stick is held against the bod in the tap hole until it sets in the hole and the stick generally takes fire from the heat of the spout. On this account they soon become small near the ends and have to be sawed off; for this reason they are always made longer than necessary and sometimes larger in diameter.

The combination stick is made of the same diameter as the wood stick, and from 4 to 10 feet long. An iron ring is placed on one end of the stick, and a rod of round iron of from ½ to ⅝ inch diameter and 1 to 3 feet long is placed in the end of the stick. On the end of the rod is placed a round button of from 1½ to 2 inches diameter, for carrying the bod. The object of the rod is to prevent the stick being burned by the heat of the spout every time the cupola is stopped in, and the length of the rod is made to correspond to the length of the spout. The objection to the combination stick is that the button does not carry the bod as well as the wood stick, and the button and rod must be wet every time it is used to keep it cool, or the heat would dry out the bod and it would fall off. This repeated wetting rusts the button, and if the edges come in contact with the molten iron it makes the iron sparkle and fly, and for this reason most founders prefer the wood sticks, even at the extra expense of keeping them up.

An iron rod and button without the wood stick is also used in some foundries for stopping in, but they were not used by our grandfathers and are not popular with melters. Three or four bod sticks are provided for each cupola. They are placed on end in a rack alongside of the tap bars, within easy reach of the tap hole, and a bod is kept on each stick all the time the cupola is in blast.

Bod Material.

The bod is a plug used for closing the tap hole when it is desired to stop the flow of iron from a cupola, and the material of which the bod is composed has a great deal to do with the nice working of the tap hole. When the bod is composed of fire clay, or largely of fire clay, it does not give up the water of combination rapidly, and if a tap is quickly made after stopping in the iron sputters and flies as it comes out of the hole. If the bod is permitted to become perfectly dry it bakes so hard it cannot be cut away with the hand bar, and the heavy bar and sledge have to be used to make a hole of the proper size. If a friable sand is used it crumbles easily before the bar and a nice clean hole can be made, but it does not hold well, and if the cupola is stopped in for any length of time the bod may be forced out by the pressure of metal.

Some of the loams make an excellent bod that holds well and is easily cut away with the point of the bar, and leaves a clean hole. Some of the molding sands also make good bods in their native state, and there are several materials that are peculiar to certain localities that make good bods. When a suitable material cannot be found it must be made by mixing two or more materials. A good bod is made by mixing blue or yellow clay and molding sand. When these clays cannot be procured a good bod can be made by mixing just enough fire clay with the molding sand to give it a little more adhesive property, but not enough to make it bake hard. When a large body of iron is collected in the cupola before a tap is made the bod material must be strong, and bake in the hole sufficiently hard to resist the pressure of the iron, and an entirely different material must be used for this kind of tapping than is used when the cupola is only stopped in for a few minutes at a time.

Small cupolas from which only a small hand ladle is drawn before it is stopped in also require a different bod, for the hole has hardly time to clear itself before it is stopped in again, and if the bod burns hard or sticks in the hole, the hole is so hard to open that the small amount of iron is chilled by the bar and slow tapping before it can be run out. This kind of a cupola requires a bod that will crumble and fall out as soon as touched, or burn out as soon as the hole is opened. A nice bod is made for this kind of work by mixing clay, molding sand and sawdust and making it fully half sawdust. Blacking or sea coal are also mixed with bod material to make it more porous when burned and crumble more readily when tapping.

Horse manure was at one time considered to be one of the essentials of a good bod, but it has been replaced by blacking or sawdust and is seldom used. A good bod should have strength to resist the pressure of molten iron in the cupola and at the same time break away freely before the iron and leave a clean hole. Such a material can be made suitable for any cupola, no matter how it is tapped, and a bod material should never be used that requires the sledging tap bar to open the tap hole.

Tapping and Stopping In.

When the blast is put on the tap hole is always open, and it is left open until the iron melts and flows freely and hot from the hole. This is generally in from 5 to 20 minutes after the blast is on. While the melter is waiting for the iron, he arranges his tap bars, bod

*Copyrighted, 1894, by Dr. Edward Kirk.

stuff and bod sticks and places a bod on each stick to be ready for instant use. The bod material is worked a little wetter than molding sand to make it adhere to the end of the bod stick or button, but care must be taken not to have it too wet or it will make the iron fly when stopping in, and, furthermore, the bod does not hold well when too wet. The bod is made by taking a small handful of the bod stuff and pressing it firmly on the end of the stick with the hand. The size and shape the bod is made depends upon how the iron is tapped and the size of tap hole. When the hole is small and only stopped in for a few minutes at a time a small bod stick is used and the bod made very small and shallow and only pressed into the hole a short distance, so it can be quickly broken away when tapping. When the hole is large or has to be stopped in until a large body of iron collects in the cupola, the bod is made large, long and pointed, so that it may be pressed well back into the hole and stay in place until removed with the tap bar.

The first iron melted flows from the hole in a small stream, and generally chills in the hole or spout and has to be removed with the tap bar; but it soon comes hot enough to clear the hole, which is then closed, unless the first iron is used to warm the ladles and the hole is kept open through the heat. If the work is light, a small tap is made in a few minutes to remove any iron that has been chilled and dulled by the dampness in the sand bottom. But when the work is heavy this tap is not made and the molders go on with their regular pouring from the start. The tap is made by placing the point of the bar against the bod and giving it a half forward and back rotation and at the same time pressing it into the bod, or by carrying the handle end of the bar around in a small circle and at the same time pressing it in. As soon as the bod is cut through, the bar is run into the hole once or twice and worked around a little to remove any of the bod that may be sticking around the sides of the hole. The bar must always be held in such a position as will make the hole in a line with the spout, or the stream will not flow smoothly and may shoot over the sides of the spout and burn the men catching in.

When about to stop in, the bod is placed directly over the stream close to the tap hole and the other end of the stick is elevated at a sharp angle from the spout. The hole is closed by a quick downward and forward movement of the stick that forces the bod into the hole and checks the stream at once. The stick is then held against the bod for a few seconds until the force of the stream is stopped and the heat has set the bod fast in the hole. The part of the bod that does not enter the hole is then removed with the stick to keep the spout clean, and the stick is dipped in water to cool it, and another bod applied to be ready for the next time. There is a great knack in stopping in that some melters never acquire. They hold the bod too far from the hole, and attempt to push it up, under or through the stream; they get nervous and are not sure of their aim and strike the stream too soon, or the side of the hole, and the iron sputters and flies in all directions.

The bod sticks are frequently made so long and slender or so heavy that it is impossible to accurately place the bod, and it is sometimes difficult to get the cupola stopped in with these long sticks. It is also difficult to stop in when the cupola is placed very high, for the melter cannot get up to place the bod stick at a proper angle for stopping in, and has to run the bod up through the stream in place of cutting off the stream with the bod. An arm or bracket is sometimes placed over the spout near the tap hole, when long bars and sticks are used, upon which to rest the tap bars and bod sticks when tapping and stopping in. But a better plan is to construct a movable platform that can be placed alongside the spout for the melter to stand on. He can then use short bars and sticks, and has much better control of the tap hole than with the long bars and sticks.

At the tap hole is seen the skill of the melter in the results obtained from his labor. If the bed has been burned too much the first charge comes down fast and slack or dull. If the bed is too high the first iron is a long time in coming down. If too much fuel is used the iron melts slow and is dull toward the last if the heat is long. If the charges of iron are too heavy the iron comes dull at the end of each charge. If the charges of fuel are too large there is slow melting at the end of each charge. If the iron flows from the tap hole with great force and is difficult to control the sand bottom has too much pitch. If slag flows freely from the tap hole with the iron the hole is too large or the bottom has too much pitch. If the spout melts, crumbles or chips off, the material is poor or has not been properly mixed. If the tap hole cuts out the material is poor and the tap hole has not been properly made. If the tap hole gums up and cannot be kept open the front material is poor and is melted by the heat, and it may be melted by the heat when it is good if rammed soft and ragged inside. If the tap hole cannot be opened without a sledge and bar the bod bakes too hard and the material should be changed. If the bod does not hold, the material is not good or the bod is not put in right. If the cupola does not melt evenly through the heat and the same every heat, it is the fault of the melter and not of the cupola.

Half a Century in Business.

"A Golden Jubilee," is the title of a pretty little pamphlet about 4 inches square which reaches us from the Anshutz-Bradberry Company of Pittsburgh, Pa. It is issued in commemoration of the fiftieth anniversary of the establishment of the business and contains as a frontispiece a likeness of Henry Anshutz, who was the founder of the Anshutz Bradberry Company. The opening pages describe the primitive cook stove and heater and gradually lead up to a description of the Tremont stoves and warm air furnaces, which are made by the concern named. An interesting feature of the little pamphlet is found in the remarks about the firm and its members. In 1792 George Anshutz, an uncle of the founder of the firm, went to Pittsburgh and erected the first blast furnace west of the Alleghany Mountains. Fifty years later Henry Anshutz, his nephew, together with Christian and Philip Shauer, formed the firm that has developed into the Anshutz-Bradberry Company. The start was made with only four or five men, but the proprietors determined at the outset that everything from their foundry should be of the sort that would stand the test of time and public opinion and on that basis the business increased. In 1856 Henry Anshutz became sole owner of the business, but a few years later his two sons C. W. and John H. were taken into the firm, which then became H. Anshutz & Co. In 1872 John H. died and the firm became H. Anshutz & Son. On January 1, 1879, William T. Bradberry was admitted to the firm and the name was changed to Anshutz & Co. In 1886 Henry Anshutz, the founder of the firm, retired and his two sons Frank and Lewis A. were admitted as partners, the title of the concern being Anshutz, Bradberry & Co. On October 9, 1887, Henry Anshutz died after having lived to see the business he had started in a small way grow to one of the largest of its kind in the country. In 1892 William McCullough and L. M. Armor were admitted as partners and the firm was incorporated as the Anshutz-Bradberry Company. Following this reference to the history of the concern, the pamphlet describes the present plant and presents an illustration of the foundry in 1844 and at the present time. The officers of the concern are W. T. Bradberry, president; Frank Anshutz, vice-president; Lewis A. Anshutz, treasurer; William McCullough, secretary, and L. M. Armor, manager of the sales department.

Samuel Freeman.

At a recent meeting of the furnace and stove trade of Boston the following resolutions on the death of the late Samuel Freeman, for many years connected with the Magee Furnace Company of Boston and Chelsea, were adopted:

Whereas, It has pleased Divine Providence to call from among us our business associate, the late Samuel Freeman, whom we have known and respected for many years; therefore,

Resolved, That we, the members of the furnace and stove trade of Boston, hereby record our high estimate of his worth as a citizen, his sterling integrity of character as a business man, his faithfulness to his friends, his loyalty to his business associates and his enthusiasm in any cause which he espoused.

Resolved, That we extend our sincere sympathy to the family of the deceased in their affliction.

ODD PLATES.

To the correspondence department of Rathbone, Sard & Co.'s Albany plant has been added some artistic letter paper. It is embellished with a combination engraving of the various plants and offices of the company and is handsomely lettered. The design is particularly attractive.

The directors of the Warren Hardware Company of Warren, Ohio, held a meeting two weeks ago and appointed W. D. P. Knowlton, J. C. Shook and W. S. Kernaohan a committee to secure a site for the erection of a building 40 x 150 feet and two stories in hight, to be used in the manufacture of ranges. The plant now occupied by the company on Main street is inadequate for the purpose, and greatly increased facilities are necessary. The castings now used are made by the Trumbull Mfg. Company, but as soon as the new works are completed the castings will be made there. With their present facilities the company can turn out about 20 ranges a week, but with their new plant they expect to be able to turn out from 15 to 25 a day.

The Central Stove Works, which is a reorganization of the house of Forster Brothers, Lebanon, Pa., were incorporated during the past week, with a capital stock of $30,000. The Board of Directors includes John Fox, Col.

John B. Embich, Jacob E. Reinoehl, Richard Stanley, A. D Bechtel and George W. Black. The officers are Col. John B. Embich, president; Brooke B. Forster, secretary; Dr. J. R. Beckley, treasurer, and Charles Forster, superintendent.

PLANS for new houses, says the Philadelphia *Record*, are now generally made in that city with attachments for gas stoves.

THE STOVE MANUFACTURERS' REPAIR ASSOCIATION OF PEEKSKILL, N. Y., have been incorporated, with a capital of $12,550. Among the directors may be mentioned Henry T. Richardson, Joshua H. Cort and Robert B. Keeler.

AN ATTRACTIVE advertising novelty in the shape of an Acorn mirror has been gotten out by Rathbone, Sard & Co. of Albany, N. Y. It is of the same size and shape as the Acorn calendar and is done in blue and silver. On one side is a bit of glass that will be handy many times a day, as well as cause "reflections" on the value of Acorn stoves and ranges.

THE CORTLAND-HOWE VENTILATING STOVE COMPANY, Cortland, N. Y., resumed operations at their foundry with nearly a full force on Monday, March 26. The plant is one of the important ones of Cortland, and it reaumes operations after a shut down since early in December, running on orders for the fall trade.

THE PENINSULAR STOVE COMPANY of Detroit, Mich., are represented at Union City, Pa., by Fuller & Everson, who have met with gratifying success in the introduction of Peninsular stoves, ranges and heaters. In a recent issue of the Union City *Times* the firm presented a full page advertisement, profusely illustrated, and showing, among other things, views of Peninsular cook stoves and ranges. This firm are noted for their enterprise and push and are doing an excellent business.

FROM the Ajax Iron Works, Corry, Pa, a catalogue of the Daisy gas burners is received. The burners are made for cooking stoves, heating stoves and open grates, and large sectional burners are made for use in furnaces and boilers.

AN EASTER GREETING has been received from the Northwestern Stove Works of Minneapolis, Minn. It is a very pretty card, showing a colored picture, inclosed in a heavy mat, of two girls. The card is looped at one corner for hanging.

THE PHILLIPSBURG STOVE WORKS of Phillipsburg, N. J., resumed operations a short time ago with a force of about 50 men after a protracted shut down.

THE GEM CITY STOVE MFG. COMPANY of Quincy, Ill., have increased their capital stock to $70,000.

A PRESS DISPATCH from Marengo, Ill., under date of March 22, is to the effect that the employees of the Collins & Burgie Stove Company struck on that day for the restoration of 5 per cent. which had been taken from their wages.

DURING their recent shut down the Albany plant of Rathbone, Sard & Co. was thoroughly overhauled, and many arrangements made and improvements instituted to increase the facilities for turning out goods.

THE FULLER-WARREN COMPANY, Milwaukee and Chicago, have issued a little catalogue for the spring of 1894, which calls attention to the company's line of P. P. Stewart stoves and ranges adapted for all kinds of fuel. The opening pages are devoted to sectional views showing the company's patent oval fire box fitted with oscillating draw center anti-clinker grate, and also with duplex grate. The goods shown include, in addition to P. P. Stewart stoves, the Matchless, a six-hole range for hard or soft coal or wood, the F.-W. Co. steel oven range for anthracite coal made with single and double ovens, the Royal Diamond range for wood, and the National Diamond made from patterns of the Royal Diamond and having the same measurements and improvements.

THE HOWARD FURNACE COMPANY of Syracuse, N. Y., are mailing to their friends in the trade a card 5 x 7 inches in size, one side of which is used for the address and the other for advertising matter. The text is printed in red and white, the words "Howard Heaters Heat Houses" being in large display type. There are also given two illustrations of Howard heaters.

THE CLEVELAND FOUNDRY COMPANY of Cleveland, Ohio, have issued from the press an interesting catalogue of gas and oil cook stoves and heaters. The publication consists of 64 pages, each of which is ornamented with a fancy border, while the binding is in colored paper covers, carrying a side title which embodies the trade-mark of the concern. The company announce in the opening pages that the word "Puritan," as applied to oil, gas or vapor stoves, is their exclusive property and was registered as a trade-mark January 9, 1894. The catalogue is printed on a good quality of paper and profusely illustrated with cuts of the leading specialties of the company. These include the Puritan, Triumph, Defiance and Paragon oil stoves, the Acme sad iron heaters, the Puritan gas stoves and the Triumph and Puritan radiators. There is also shown a line of gas heating stoves made under the name Puritan; also the Banner, Favorite and Columbian oil heaters. Attention is also given to registers, sad irons and hardware specialties. The Eastern office and salesroom of the company is at 82 North street, Boston, Mass.

THE DANGLER STOVE & MFG. COMPANY of Cleveland, Ohio, have been assigned a patent for a heat radiator granted March 20 to Charles I. Dangler and Henry Ruppel of the place named. The invention relates to heat radiators of the variety in which gas is used for heating, and is a modification of the radiator set forth and claimed in an application filed April 6 of last year. In the present construction a single burner tube is employed, with a pair of circulating tubes, one upon each side thereof, connecting the top of the radiator with the base. The latter has openings in its edge through which the heated air is discharged into the room. The construction is such that as soon as the burner is lighted a free circulation of air is established in an upward direction in the center tube and downward in the side tubes, the heated air passing out through the openings in the front of the base. It is stated that the length of the route traveled retards the flow of the air just enough to insure good radiation, and in this respect the invention differs materially from a construction in which the burner is at the bottom of the tube and the discharge at the top. The burner tube in the present invention is provided at its lower end with a transparent globe or bulb, which serves to give out light as well as heat, thus making the device serve a double purpose.

J. D. MARVIN, representing Perry & Co. in New York City and on Long Island, has secured some very gratifying orders during the past week for gas and oil stoves. Mr. Marvin has had some 20 years' experience in the stove trade, and is well known among dealers from Maine to the Gulf of Mexico.

THE THATCHER FURNACE COMPANY of 33 Peck Slip, New York City, are actively pushing the sale of their No. 80 Thatcher range, provided with horizontal boiler. The stove is made with a fire box on either the right or left hand side, has 8-inch boiler holes, capacious oven and stands 30 inches high with a top surface 38 x 25½ inches. The range is made with or without water back, and is furnished with revolving or flat grate, as may be desired. The company's Champion steam heater is meeting with favor among architects, builders and the trade in general, several large orders having been received during the week for shipment to their agents in the West.

E. K. CONANT, 9 West Fourteenth street, New York, is showing the summer line of gas stoves made by the Dangler Stove & Mfg. Company, Cleveland, Ohio. This year the rangea have a handsome new front and a cabinet base. One of the special features is the oven ventilation, a current of hot air passing continually through, and so arranged that opening the oven door does not let the cool currents strike the food. A water heating coil for use in connection with a kitchen boiler is supplied this year with the smaller size and at a popular price. A patented device is used to deflect the flame of the cooking burner to the coil, and can be removed when the full heat is desired at the top of the stove.

GEO. F. PRENDERGAST has just finished a successful trip through New England, selling gas stoves for the Dangler Stove & Mfg. Company, Cleveland, Ohio. One of his new customers is the Gas Mfg. Company, at Haverhill, Mass., who are making their first venture in the gas stove business by placing an order for an assorted carload of the Dangler stoves.

WM. M. CRANE & Co., 838 Broadway, New York, made an exhibit of a model gas kitchen at the Food and Home Exposition at Lenox Lyceum. It was equipped with one of their steel ranges, with an adjustable rising hood, water heater, broiler and a variety of special gas cooking utensils and appliances. An exhibition of their practical use was given in the evening, when cooking, baking and broiling were done and the delicacies submitted for the approval of the interested visitors.

EDWARD LANGE is visiting the gas stove trade in New York in the interest of Geo. M. Clark & Co., Chicago, and showing the new features of the Jewel line of gas cooking and heating stoves.

E. O. & W. K. STAFFORD will open a branch office and warerooms at 7 West Fourteenth street, New York, May 1, as Eastern managers for the Milwaukee Gas Stove Company of Milwaukee, Wis. They now have on exhibition, temporarily at 4 West Fifteenth street, a fine line of the Perfection cast iron and steel ranges, hot plates, portable stoves, water heaters, heating stoves, grates, china kilns, tinners and plumbers' furnaces, coffee roasters and cooking uten-

sils. They will also act as the Eastern representatives of the Mosely Folding Bath Company of Chicago, Ill., and the Erwin Hydraulic Machinery Company of Milwaukee, Wis.

The March-Brownback Stove Company of Pottstown, Pa., have resumed operations at their works and are running steadily. They report a large demand for their Crown furnace. The furnace is made in two styles, portable and brick set, and is adapted to soft or hard coal. The construction of the furnace for soft coal is very unique. The air enters above the bridge and at a point which allows of the complete combustion of fuel and gases. The company state that last year's business was as good as could be expected, considering the depression which has prevailed. Collections have been slow and a lot of stock has been carried over.

William J. H. Gluck of Baltimore, Md., sends us a package of advertising matter relating to his leading specialties. One of the circulars illustrates and describes the Gluck four-hole cook stove, which is said to represent the culmination of 20 years' experience. The statement is made that "every feature that concerns the art of cookery has been investigated, every principle involved in the theory of drafts, juxtaposition of flues, size of fire box, shape of oven, and the loss of heat and air has been thoroughly examined and every known invention appropriated. The mixture of irons, its strength, its resistance to expansion and contraction so as to prevent cracking have been perfectly researched. Every good feature in the old pattern has been retained and all new improvements have been added, making the Gluck cook the most perfect stove ever invented." A well arranged catalogue of 20 pages gives attention to some of the leading stoves sold by Mr. Gluck, many of the engravings being reproduced directly from photographs. The list includes the Ivy Fortune five-hole range, the Active Fortune, with Hayes' horizontal boiler, the Westside range, the Home Fortune, the Regal Fortune, the Star Fortune and the Fountain. There is also shown a line of heaters, including the Electric Franklin and the Heckla Fortune. Other circulars give attention to stove boards, milk cans, Gluck's non-explosive oil stove, refrigerators, May Queen ice cream freezer, Iron Clad enameled iron ware, steam cookers, sand shovels and ovens for gasoline stoves.

Bergstrom Bros. & Co. of Neenah, Wis., manufacturers of Royal stoves and ranges, send us a batch of printed matter which they are now distributing. One circular illustrates the firm's patented deflecting damper, by means of which all the heat may be diverted to either side of the stove top, thus controlling the heat and applying it where it is most needed at the time. The other circulars consist of enameled blotting pads, one of which illustrates the Ensign four-hole range for soft coal and wood, fitted with deflecting damper; another shows the Medal four-hole range for wood only, fitted with patent deflecting damper; a third presents the Emblem four-hole range for hard coal and wood, which is made in various sizes and styles.

Eugene Munsell & Co. of 218 Water street, New York City, are renovating their five-story warehouse. When the improvements are completed the company expect to have one of the finest stove warehouses in the city. Their mica and micanite business has increased to such an extent that the entire third floor of the warehouse will be set apart for that department. A new telephone has been installed in their counting room, their telephone number being "968 Cortlandt," which can be used by dealers in remote sections of the city and nearby places in ordering Manhattan ranges, gas stoves, mica, &c.

Trade Notes.

In his advertisement, appearing elsewhere in this issue, W. J. Rothweiler, 98 Third avenue, Pittsburgh, Pa., directs attention of the trade, and of tinners particularly, to the Economy Hollow Punch. This punch is referred to as being self centering and automatic extracting. The fact is also referred to that with the use of this punch damage from careless use necessitates ordering simply a new cutter, rendering it unnecessary to throw away the entire tool. By this means a considerable saving in cost is effected. These cutters are referred to as being made of English cast steel, finely tempered, while the shanks are made of hexagon American steel, also tempered, to prevent wearing down as much as possible. The punches are made in sizes from ⅛ to 2 inches inclusive, and the further announcement is made that they are sent C.O.D. to any address, and the trade are invited to write for description and prices.

The Philadelphia Ornamental Wire Company, 18 North Sixth street, Philadelphia, Pa., make announcement to the trade that they have placed their line of Wire Goods and specialties in the hands of O. N. Stein, 35 Warren street, New York, where a full line of their samples can be seen.

R. G. Sykes of the Sykes Iron & Steel Roofing Company, Niles, Ohio, has made a proposition to the citizens of that place, agreeing to build a rolling mill and two sheet mills, with all necessary buildings, machinery and appliances to operate the same, and requiring 75 men to operate sheet mill, within six months from April 1, 1894. The company to be incorporated, with a capital stock of $100,000, one-half of which shall be paid up immediately, provided that the Council of Niles issues city bonds to the said Sykes in the sum of $10,000, which the said Sykes agrees to take at no less than par value. The proposition of Mr. Sykes was accepted by the Council of Niles, and it is probable that work on the new mill will be commenced within a short time.

The Ellwood Ivins Tube Co., Philadelphia, Pa., are drawing a series of tubing samples for C. D. Mosher, the marine engineer. When delivered they will be subjected to severe tests for the purpose of determining the availability of employing similar tubes in the construction of boilers to be erected in three or four United States naval vessels, contracts for which have been awarded him. This mill is also about commencing the manufacture of tapered tubes drawn in all metals, with walls of uniform thickness. They are now drawing high carbon tubes up to ¼-inch and low carbon to 5-inch, inclusive. In all the other metals they are prepared to draw seamless tubes from $\frac{1}{64}$ to 5 inches in diameter, any desired form, either round, square, corrugated, &c., with any thickness of wall. They call especial attention to their aluminum and aluminum bronze seamless tubing, the latter they assert never before made, especially valuable, they claim, on account of great tensile strength and rigidity of the metal, together with its non-corrodibility and high heat conductivity.

The Indestructible Clay Wick Company of New York were incorporated last week, to manufacture Clay Wicks for burning oils and other liquids in lamps, stoves and other devices; capital, $150,000; directors, Geo. L. Eastman, Jos. T. Murray, John F. Shennan, John A. Cutler and Martin A. Korff of New York City and Mrs. Ida R. Eastman of Brooklyn.

C. Pratt, 69 Beekman street, New York, is offering the Crown Asbestos Griddle, manufactured by Hall & Carpenter, Philadelphia, Pa., which is a novel cooking utensil designed for frying small quantities of food without scorching or burning, and is sold, we are advised, at a very moderate price.

Eaton, Cole & Burnham Company, 82-84 Fulton street, corner of Gold, will, on or about May 1, occupy their new quarters in the seven story building fast approaching completion, at the corner of Beekman and Gold streets. This building, which extends back from Beekman street to Ann, is within 200 feet of where they now are.

The Star Coupler Company, St. Louis, Mo., have increased their capital stock from $20,000 to $30,000. They report a heavy demand for their Star Water Back and Boiler Couplers, which, they advise us, are indorsed by all manufacturers and dealers in ranges and heaters. In their advertisement in this issue they state as follows: "Sample orders shipped to any address and satisfaction guaranteed." This will enable the dealer to judge for himself whether or not the device which this company are advertising is what they claim for it.

The workmen of the Crane Company of Chicago, manufacturers of wrought pipe and plumbers' and steam fitters' supplies, have struck against a reduction of wages. The company advanced the wages of their men last year voluntarily, in view of the fact that living expenses in Chicago had been raised considerably by the World's Fair, and they now make a reduction in order to be able to compete with other establishments in the same line who are making sales at very low prices. The officers of the company have treated their men so considerately in the past that they are of the opinion that the reduction now made should be accepted without a murmur, when it is certainly known that reductions have been made in workmen's wages almost everywhere else. Their workmen, however, look at the matter from another standpoint. Under the leadership of professional labor agitators, they assume that the corporation are so wealthy that they can afford to pay high wages indefinitely, and charge that the real reason for lowering wages is to get in position for cutting prices. They proposed arbitration and an examination of the books of the company to ascertain if the reduction was really warranted. This the company have rejected. About 2500 workmen are out of employment on account of this disagreement. As usual, they indulge in bitter speeches against their employers. They are endeavoring to induce the Building Trades Council of Chicago to declare a boycott on all goods made by the company so as to cripple them through their sales department. The employees of the Crane Elevator Company, another corporation managed by the same capitalists, are also on a strike against a reduction of 15 per cent. in their wages. They number about 200 men.

TRADE REPORT.

The Iron Market.

The feeling in the Iron trade throughout the country is a slight shade better, and is due chiefly to the fact that the large Pittsburgh mills seem to have gotten their order books into slightly better shape, and are not as desperate as they were. Billets are firmer and cannot now be bought under $15.50, Pittsburgh.

Merchants and mills are crowding buyers for specifications on the ground that they have intimations from the railroads that present cut rates of freight may be recalled at any time and higher figures be substituted at ten days' notice.

Pittsburgh and Valley Foundry Iron makers are hunting for orders in Eastern territory, and claim to have a further fighting margin if present prices made by them do not bring them the business they want. Some consumers of Foundry Iron are taking advantage of the eagerness of sellers and are contracting for Iron far toward the end of the year. But the great majority cannot be tempted by any concessions to engage their future requirements.

No one expects a revival of business before something final has been done in Congress. Since even the most sanguine in Washington hold out little hope before the end of June, buyers feel pretty confident that chances now offered will occur again at some time during the next three months. Under the circumstances the stocking up movement which is expected to start the quick upward turn is yet quite far off—apparently.

While this condition of affairs continues no lasting rise in prices is looked forward to. As it is, the withdrawal of one great seller simply brings another hungry mill into prominence. Still, record breaking has pretty well stopped, although the lowest prices are still being made on every important transaction coming up.

American Pig.—The market in the immediate vicinity of New York has continued quiet, although the situation has become more complicated through the more urgent offering of Pittsburgh, Mahoning and Shenango Valley Foundry Irons. Excellent Iron from the last two districts is being offered at $12.30 for No. 2 Foundry, and it is intimated that even lower figures can be made for tempting business. The majority of sellers of standard brands decline to contract beyond July, but some of the Southern furnaces are going beyond that time at current prices. Virginia furnaces in particular are competing sharply and are giving long time options to capture new trade. The furnaces in the Lehigh Valley have been granted reductions in freights to New England points, the rates to Worcester, Springfield and other points having been made $1.75 against $2.50 formerly. It is reported also that the Eastern Pennsylvania furnaces are getting cheaper anthracite coal, and have secured lower freights on ore and other materials. We quote standard brands $12 75 @ $13.50 for No. 1; $12 @ $12.50 for No. 2, at tidewater. Southern Iron, same delivery, $12.25 @ $13 for No. 1; $11.00 @ $11.50 for No. 2; $10.75 @ $11.25 for No. 3; $11.25 @ $11.75 for No. 2 Soft, and $11.75 @ $12 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10.50 @ $11.

In the Philadelphia district the Pig Iron market holds its own, which, under the circumstances, is a satisfactory feature. With 10,000 tons a week increase in the supply, and with lower freights from competing points, this circumstance is regarded as surprising. There is, however, no certainty in regard to the immediate future, although with a moderate increase in the demand somewhat better prices might be expected, or the reverse if the supply keeps on increasing without a corresponding increase in consumption. General quotations are about as follows for Philadelphia and equivalent points, with the heaviest end of the business at inside figures:

No. 1 Foundry	$13.00 @	$13.25
No. 2 Foundry	12.25 @	12.50
No. 1 Soft	12.00 @	12.25
No. 2 Soft	11.00 @	11.50

The Chicago market has been less active, but local Irons have taken the lead in whatever business has been done. Large transactions are rare, the week showing but one sale of 1000 tons. Southern manufacturers appear to be anticipating a drop in freight rates, as they are now endeavoring to make contracts at a delivered price instead of at the furnace, as heretofore Lake Superior Iron is moving only in single carloads, but the time is fast approaching when some good sized contracts are to be expected from large consumers who have not yet completely given up the use of Charcoal Pig Iron. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @	$15.25
Local Coke Foundry, No. 1	11.75 @	12.25
Local Coke Foundry, No. 2	11.00 @	11.75
Local Coke Foundry, No. 3	10.75 @	11.00
Local Scotch	12.00 @	12.50
Ohio Strong Softeners No. 1	13.00 @	14.00
Southern Silvery, No. 1	@	12.50
Southern Silvery, No. 2	@	11.75
Southern Coke, No. 2	11.25 @	11.50
Southern Coke, No. 3	10.75 @	11.00
Southern, No. 1, Soft	11.25 @	11.50
Southern, No. 2, Soft	10.75 @	11.00
Tennessee Charcoal, No. 1	15.50 @	16.00
Tennessee Charcoal, No. 2	15 00 @	15.25
Alabama Car Wheel	18.50 @	18.65
Jackson County Silvery	15.00 @	16.00
Other Ohio Silvery	13.00 @	13.50

There is not a great deal of Pig Iron offering in the Pittsburgh market just now, nor on the other hand is there a heavy demand for it. Foundry Iron is neglected and weak in price. Quotations are given as follows:

No. 1 Foundry	$11.50 @	$11.75
No. 2 Foundry	10.50 @	10.75

Weakness has been the characteristic feature of the week in Southern Pig Iron markets. The volume of business is reported as fair in a small way and there was a good inquiry for moderate quantities from one to ten carloads, with sales generally effected, for there is a disposition to supply the wants of consumers without allowing the price to interfere. For instance, No. 2 Foundry has been sold on the basis of $7 ℔ ton, f.o.b. Birmingham, and if there was any demand for No. 1 a relatively low price would doubtless be made, for there is an accumulation of stock, while the lower grades are better sold up and are less urgently offered. There is no movement in Charcoal Iron. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$11.00 @	$11.25
Southern Coke, No. 2	9.75 @	10.00
Southern Coke, No. 3	9.50 @	9.75
Ohio Soft Stone Coal, No. 1	14.50 @	15.50
Ohio Soft Stone Coal, No. 2	14.25 @	14.50
Lake Superior Coke, No. 1	13.00 @	13.50
Lake Superior Coke, No. 2	12.00 @	12.25
Hanging Rock Charcoal, No. 1	17.00 @	17.50
Hanging Rock Charcoal, No. 2	16.50 @	17.00
Tennessee Charcoal, No. 1	13.50 @	14.00
Tennessee Charcoal, No. 2	12.50 @	13.00
Standard Southern Car Wheel	16.75 @	17.50
Lake Superior Car Wheel and Malleable	16.50 @	17.00

Metal Market.

Pig Tin.—Straits Tin has advanced in price to the extent of about ¼¢ ℔ lb. Five-ton lots were sold at 19.30¢, net cash, for prompt delivery, and 19.40¢ @ 19.50¢ was paid on the exchange for August delivery. Speculation is still very tame and almost wholly between a few local operators, but sales to jobbers and consumers have increased somewhat and made quite an impression upon the stocks in importers' hands. Still, the consumptive demand is hardly up to the average for this season of the year. Prices for small retail lots of Tin remain at about 21¢ ℔ lb from store. The advance in price of the metal during this month has been marked, especially in respect to future deliveries. Early in the month April delivery was offered at as low as 18.25¢ and distant futures at a considerable dis-

count, including August at 17¢. During the past week April delivery went to 19.25¢ and sales were recorded of August at 19.40¢ @ 19.50¢. This radical change in quotations is at least suggestive.

Copper.—Reports were decidedly in contrast with those of the preceding week, as far as reference to business is concerned. Without exception they indicated a decided falling off in transactions, and were not without evidence that the demand has dropped off in a somewhat surprising manner. The offering has, meanwhile, continued quite free and of sufficient weight to slightly weaken prices. Thus 9.50¢ has become a common selling price for Lake Superior Ingot here, while private advices intimate that a lower rate has been quoted in the English market. Electrolytic has been sold here at 9.30¢, and rumors prevail of business having been put through at a shade less, but it is claimed now that Pig Copper can be sold at a relatively better price in foreign markets. Casting Copper, well known brands, is offered at 9⅛¢, and as low as 9¢ is said to have been accepted for some that are not very popular. Jobbing prices for small quantities of Lake Ingot are rather easier, 10⅛¢ ℔ lb being now about the outside asked.

Sheet Copper.—In another column will be found the new price-list agreed to by all the Copper manufacturers of the United States for Sheet and Bolt Copper and Copper Bottoms, in order to regulate the market for these materials. The new terms are net, without discount. For small retail lots from store an advance of about 1¢ a lb is generally charged over the list prices. The demand for Sheet Copper has sagged off considerably during the past week, and purchases by consumers are on a very conservative scale.

Pig Lead.—Sales have fallen off considerably, but prices are held quite firmly. The demand is much slower than it was during the ten days or fortnight preceding the week under review, and the appearances are that dealers who sold "short" some time ago have covered to a great extent. There is little trade demand at present, in any event, and large consumers seem to be quite indifferent, while the requirements of the smaller consumers appear to be exceedingly moderate. Prices stand at 3.40¢ @ 3.50¢, according to brand and terms of sale, with an advance of about ⅛¢ for small jobbing lots.

Spelter.—There has been no improvement in business here, and purchases at other points, it is reported, have fallen off more or less. To this extent the market is weaker in tone. Prices are not positively lower, however, and the offering is not much freer, if at all larger, than it has been previously this month. Prices do not vary a great deal from the basis of 3.80¢ @ 3.85¢ for ordinary Western brands, with the usual premium on small quantities.

Sheet Zinc.—Business is behind the average for the season, and prices are inclined to softness. Quotations are 4¾¢ ℔ lb for cask lots and 5¼¢ for smaller quantities.

Tin Plates.—Although orders are somewhat more numerous than they have been of late, the aggregate volume of business does not show much, if any, increase. Calls are almost entirely for small lots for present use, and all buyers seem to be entirely conservative in their purchases. Dealings are, on the whole, backward for the season. Futures are generally neglected, and the business passing is little beyond what is forced by imperative wants. Roofing Plates are spoken of as the most active feature of the market at present. Little, if any, concession in prices has been made, but selling pressure is still sufficient to keep the market weak in tone. A special cable dispatch from London to *The Iron Age*, of March 28, reports the British Tin Plate market to be without radical change. Special sizes have been in quite good demand, but business otherwise has been confined to cheap lots for prompt shipment. Included in the latter were 14 x 20 Bessemer Cokes at 9/9, f.o.b. Wales. Liverpool quotations are quoted as follows:

IC Charcoal, Alloway grade	12/ @ 12/6
IC Bessemer Steel, Coke finish	@ 10/6
IC Siemens " "	11/ @
IC Coke, B. V. grade, 14 x 20	Nominal.
Charcoal Terne, Dean grade	10/ @ 10/6

Sheet Iron.—Black Sheets are dull and prices weak. Galvanized Iron is, however, moving fairly well and maintains a firm tone.

Production of Spelter.

David T. Day. Chief of the Division of Mining Statistics and Technology, United States Geological Survey, has issued the following preliminary statement by C. Kirchhoff, agent, of the production of Spelter and Zinc Oxide for the year 1893:

Production of Spelter in the United States, by States (Short Tons).

States.	1891.	1892.	1893.
Eastern and Southern States	13,162	14,495	12,684
Illinois	28,711	31,383*	29,596
Kansas	22,747	24,715	22,815
Missouri	16,253	16,567	13,737
Totals	80,873	87,160	78,832

*Including Indiana.

The decline in the output took place entirely during the second half of the year, as follows:

States.	First half 1893.	Second half 1893.
Eastern and Southern States	7,380	5,304
Illinois	16,427	13 169
Kansas	13,269	9,546
Missouri	8,718	5,019
Totals	45,794	33,038

Stocks of Spelter on January 1, 1894, were as follows:

Stock of Spelter.

States.	January 1, 1893.	January 1, 1894.
Eastern and Southern States	3,316	3,796
Illinois	12	974
Kansas	483	335
Missouri	349	379
Totals	4,160	5,484

The exports of domestic Spelter in the past year were 3639 tons in 1893, and 6247 net tons in 1892, as compared with 2147 net tons in 1891.

The production of Zinc Oxide is estimated at 24,059 tons, of which 14,954 net tons was produced in the Eastern district, as compared with 19,129 tons in 1892, and 9150 was made in the West in 1893, as compared with an estimate of 7700 tons in 1892.

The American Metal Company have issued the annual statement of Henry R. Merton & Co. on the production of Spelter in Europe:

Spelter Production in Europe.

	—Gross tons.— 1893.	1892.
Rhine District and Belgium	149,750	143,305
Silesia	90,310	87,760
Great Britain	28,375	30,310
France and Spain	20,585	18,662
Austria	7,560	5,120
Poland	4,530	4,270
Total Europe	301,110	289,327

Chicago Report.

Scrap.—Cast Scrap is moderately active, but other descriptions of Old Material are neglected. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....
No. 2, such as Shovels, Hoes, &c	3.00	....
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5 ¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5⅛¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—Prices are very weak in the absence of a demand. Carload lots of 12 net tons or over are nominally quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.85	$6.10
Milwaukee, Wis	5.85	6.10
Kansas City, Mo	9.05	9.30
Council Bluffs, Iowa	9.05	9.30
Lincoln, Neb	9.20	9.45
Sioux City, Iowa	9.05	9.30
Aberdeen, S. Dak	9.10	9.35
Dubuque, Iowa	7.15	7.40
Madison, Wis	7.35	7.60
St. Paul, Minn	8.35	8.60
Burlington, Iowa	7.35	7.60
Des Moines, Iowa	8.80	9.05
Davenport, Iowa	7.15	7.40
St. Joseph, Mo	9.05	9.30
Leavenworth, Kan	9.05	9.30
Omaha, Neb	9.05	9.30

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.	
Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.85

THE NUBIAN IRON ENAMEL COMPANY of Cragin, Ill., announce that the second edition of their Nubian calendar is now ready for distribution. It will be mailed on application.

CONDITION OF THE

Hardware Trade.

MARCH draws to a close with a fair volume of business, there having been during the past week or two a perceptible improvement. The demand was doubtless stimulated by the fine spring like weather which prevailed, and has not apparently been seriously affected by the subsequent cold snap, which, however, it is feared has done more or less damage to the crops. It is noticeable that the trade are purchasing a greater variety of goods than for some time, their orders covering both Heavy and Shelf Hardware and seasonable goods. There is also more inquiry for Builders' Hardware and Mechanics' Tools, all the orders indicating that stocks in dealers' hands are light and that the trade are purchasing conservatively. Several houses supplying manufacturers report that their orders indicate an improvement in the demand which is made on the manufacturers and their resumption of more energetic and enterprising efforts in the prosecution of their business. Prices, we regret to report, are in a condition far from satisfactory, and on many lines of goods there is a disposition to name lower prices than have heretofore prevailed. There is also a good deal of irregularity in the prices of the jobbing trade, and some of them are naming exceptionally low prices with a view to inducing business. This cutting of prices is to be regretted, as its natural tendency is to diminish the jobbers' profits. The financial condition appears to give little cause for complaint or apprehension, collections being fair.

Advices from Chicago.—The very cold weather of the past few days has not yet been felt in any diminution of trade. The spring thus far has been extremely favorable to the Hardware interests. There has been no mud blockade, as usual. The farmers are much ahead of previous years in their preparations for crops, and are now making improvements which involve the consumption of considerable Hardware. The movement in Shelf Hardware shows more activity within the past week, and jobbers expect that March will be abreast of March of last year. The demand for small goods shows a heavy gain during January and February. The proportion was one-half to two-thirds of staple goods, but now three-fourths of the business consists of small goods and straight Hardware. An excellent business is being done in seasonable goods. Tinware and Metals are quiet. Heavy Hardware jobbers report a decided gain in the volume of business. Orders are now coming in from Carriage builders who have deferred active operations so long that they will be obliged to push things actively in order to be in proper shape to transact business this year. The demand is excellent from other manufacturing consumers who purchase supplies from the jobbers.

Notes on Prices.

Wire Nails.—These goods continue in excellent demand, and the aggregate of the business for the current month will be large. There is some complaint in regard to prompt shipments, but as a rule orders are being executed without delay. There is, however, no accumulation of stock in the hands of the manufacturers. In the matter of price the market is perhaps not quite so strong as it has been, and is represented by the quotation of $1.05 to $1.10 for carload lots at mill, the former figure being usually obtainable on good orders, while it is shaded by some of the manufacturers in special cases. Some of the mills, however, refuse to make a lower price than $1.05. Small lots from store in New York are held at $1.25 to $1.30.

Advices from Chicago.—The reduced price put in effect here upon the lowering of freight rates appears to be generally maintained. Manufacturers are well supplied with orders for future shipment, extending certainly over the next four weeks, and perhaps further. Orders for immediate delivery have been refused in some cases, because manufacturers are unable to fill them. Factory quotations are equivalent to about $1.10, Chicago. Jobbers are holding prices to the country trade at $1.20 to $1 25, but on city business there is some little irregularity. Their carload trade is light at present.

Cut Nails.—The demand for Cut Nails continues fair and the mills report the receipt of many orders, though, as a rule, they are for comparatively small quantities, the trade pursuing a conservative policy and refusing to buy beyond their immediate requirements. Some of them refer to the fact that they can see evidence of a reaction in some sections from the use of Wire Nails and a return to Cut Nails. The prices of the Eastern manufacturers for Nails delivered at the principal points in their territory are as follows: New York, Albany, Boston and Savannah, $1.05; Buffalo, $1.02; Harrisburg and Philadelphia, $1. In view of the active competition with Wire Nails and under a desire to secure what business there is going the above prices are shaded 5 and in some cases 10 cents. The price quoted for Nails from store in New York is $1.10 and $1.15.

Advices from Chicago.—Manufacturers are much pleased with the trade they are having this spring, which exceeds their expectation. While orders from the South and Southwest are large the local demand has also been good, and in some cases jobbers' orders have been unusually heavy. Specifications are coming in freely on contracts and inquiries continue to promise good business. Factory prices are now $1 on 55-cent average. Jobbers quote small lots from stock at $1.15.

Barb Wire.—The manufacturers of Barb Wire are to be congratulated on the steady and large demand and also on the regularity which characterizes prices. The trade are continuing to purchase freely and the mills are fully occupied. There does not, however, appear to be any difficulty in obtaining Wire promptly. Quotations are on the following basis for carload lots of Four Point Galvanized: Pittsburgh, $2.15; Cleveland, $2 20; Cincinnati or Allentown, $2.25; Chicago or New York, $2.35, with an advance of 5 cents per 100 pounds in less than carload lots.

Advices from Chicago.—Trade in both Plain and Barb Wire keeps up exceedingly well and prices are strong. The demand is of the same character as previously noted. Those who usually buy in carloads are taking ton lots, but they are buying much oftener, and the volume of business is kept up. Quotations are $2.35 to $2.40 for small lots of Galvanized Barb Wire from stock and $2.25 to $2.30 for carloads.

Sheet and Bolt Copper.—For some time past the market for Sheet and Bolt Copper has been irregular, the list having been quite generally discarded and much lower net prices made, representing, it is said, in some cases a discount of 50 per cent. With a view to correcting this condition of things, a revised list bearing date March 22 has been issued by the manufacturers and is printed below. Some changes have also been made in the extras. The new list, which is to a certain extent provisional and may perhaps be modified before long, is as follows, terms cash without discount:

Sheet Copper, per lb., cents.		64 oz. and over.	32 oz. and up to 64 oz.	16 oz. and up to 32 oz.	14 oz. and up to 16 oz.	12 oz. and up to 14 oz.	10 oz. and up to 12 oz.	8 oz. and up to 10 oz.	Lighter than 8 oz.
Not wider than 30 inches.	not longer than 72 inches.	14	14	14	15	16	17	20	22
	longer than 72 inches.....	14	14	14	15	17	19	23	...
Wider than 30 inches but not wider than 36 inches.	not longer than 96 inches.	14	14	14	16	18	22	25	....
	longer than 96 inches.....	14	14	15	17	19	23	27	....

	longer than 96 inches. ..	14	14	17	19	21	25	....	....
Wider than 48 inches but not wider than 60 inches.	not longer than 96 inches.	14	14	19	21	26	... ..		...
	longer than 96 inches....	14	15	20	23	. ...	.....	....	....
Wider than 60 inches but not wider than 84 inches.	not longer than 96 inches.	15	16	21	25	.....	.....		....
	longer than 96 inches. ..	16	17	22	27	.....	....	...	..
Wider than 84 inches....		17	19	....	.....	. .	....	..	...

Bolt Copper, ¾ inch diameter and over, 14 cents per pound.
Circles, Segments and Pattern Sheets, 60 inches wide and less, 3 cents per pound advance over price of sheets required to cut them from.
Circles, Segments and Pattern Sheets, over 60 inches to and including 96 inches, 4 cents per pound advance over price of sheets required to cut them from.
Circles, Segments and Pattern Sheets, over 96 inches, 5 cents per pound advance over price of sheets required to cut them from.
Cold or Hard Rolled Copper, 14 ounces per square foot and heavier, 1 cent per pound over the foregoing prices.
Cold or Hard Rolled Copper, lighter than 14 ounces per square foot, 2 cents per pound over the foregoing prices.
All Copper polished one side, not over 20 inches wide, 1 cent per pound additional to cold rolled prices.
All Copper polished one side, over 20 inches wide, 2 cents per pound additional to cold rolled prices.

Tinning.

	Cents.
Tinning Sheets, on one side, 10, 12 and 14 x 48.....each	6
Tinning Sheets, on one side, 30 x 60.....each	25
For Tinning Boiler Sizes, 9 inches (Sheets 14 x 60 inches).....each	12
For Tinning Boiler Sizes, 8 inches (Sheets 14 x 56 inches).....each	10
For Tinning Boiler Sizes, 7 inches (Sheets 14 x 52 inches).....each	8
Tinning Sheets, on one side, other sizes.....per square foot	2

For Tinning both sides, double the above price.

Copper Bottoms, Pits and Flats.

	Cents.
14 ounces and over to square foot....	18
12 ounces and up to 14 ounces square foot.....	19
10 ounces and up to 12 ounces square foot.....	21
Lighter than 10 ounces square foot..	24

All circles under 8 inches in diameter, 2 cents per pound more than foregoing price, and no circles over 13 inches in diameter shall be classed as Copper Bottoms.

Galvanized Iron Deflectors.—Baker & Smith Company, 193–197 Van Buren street, Chicago, Ill., have issued the following price list of Galvanized Iron Deflectors for Radiators, f.o.b. Chicago, ready for bronzing:

Loop.	No. 1.	No. 2	No. 3.	No 4 with evaporator.
2	$2.00	$2.60	$3.20	$4.10
3	2.25	2.85	3.45	4.35
4	2.50	3.10	3.70	4 60
5	2.75	3.35	3.95	4.85
6	3.00	3.60	4.20	5.10
7	3.50	4.20	4.90	6.95
8	4.00	4.80	5.60	7.80
9	4.50	5.40	6.30	8.65
10	5.00	6.00	7.00	9.50
11	5.50	6.60	7.70	10.35
12	6.00	7.20	8.40	11.20
13	6.50	7.80	9.10	12.05
14	7.00	8.40	9.80	13.90
15	7.50	9.00	10.50	14.75
Add for each additional loop :	.50	.60	.70	.85

The Ellis Warming Box.—This article was described in our last issue as put on the market by J. T. Ellis, Box 262, Newark, N. J. The Warming Box is sold to the trade at $1 each, subject to a discount of 25 per cent.

Heath's Ball Valve Pump.—This Pump is being put on the market by the S. F. Heath Cycle Company, Minneapolis, Minn. It was described in a recent issue. It is sold to the trade from the following list, terms 30 days net, or 5 per cent. discount for cash received in ten days from date of invoice :

	Each.
In lots of 6 to 12 Pumps.....	$1.50
" " 13 to 50 Pumps.....	1.35
" " 51 to 100 Pumps.....	1.20

Sanitary Garbage Pail.—This Pail was described in a recent issue as put on the market by the Sanitary Garbage Pail Company, Detroit, Mich. The Pails are sold to the trade at $21 per dozen for the 12-gallon size and $33 per dozen for the 20 gallon size.

Glass.—The demand for Window Glass continues moderate and the market is without special feature. Pittsburgh quotations remain as before—85 and 10 and 5 per cent. discount for single, and 85 and 20 per cent. discount for double strength Glass. The total number of pots in operation at the present time is said to be 942, but it is expected that a number of factories will resume operations within the next week or two. An advance has just taken place in French Window Glass, which is now held at 80, 10 and 5 per cent. discount. A satisfactory condition of things is reported in Imported Glass circles, the demand being fair, with an encouraging outlook for the future.

Old Metals.—The demand for certain lines of Scrap Iron is better, but as the supply is abundant prices show no change. The market for Old Metal in general continues narrow and weak. The following quotations represent dealers' purchasing price in New York:

Heavy Copper.....	℔ 7¢
Light and Tinned Copper.....	℔ 6¢
Heavy Brass.....	℔ 5¢
Light Brass.....	℔ 4¢
Lead.....	℔ 3¢
Tea Lead.....	℔ 2½¢
Zinc.....	℔ 2¼¢
No. 1 Pewter.....	℔ 15¢
No. 2 Pewter.....	℔ 6¢

It Is Reported—

That Sabine & Harvey of Boonville, N. Y., will soon remove their Hardware business to Utica.

That the Warner Hardware Company, Freeport, Ill., has been incorporated. The capital stock is $20,000. The incorporators are L. A. Warner, Geo. W. Warner and Emil A. Hoofer.

That Mr. Spettigue will soon open a new Hardware store at Honesdale, Pa.

That the G. B. Churchill Company has been formed at Galesburg, Ill., with a capital stock of $20,000. They will do a general Hardware business. The incorporators are George B. Churchill, George Churchill and M. L. Churchill.

That the Hardware store of A. S. & A. E. Cooley, Canandaigna, N. Y., will hereafter be conducted under the style of Cooley & Co., Mrs. James S. Cooley having purchased the interest in the business lately owned by A. S. Cooley.

That the Wright Bros. Hardware Company, Doniphan, Mo., have been incorporated. The capital is $10,000.

That the wholesale Hardware establishment of Sickels, Preston & Nutting, Davenport, Iowa, was burglarized on the 12th inst.

That Frederickson & Reitzel's Hardware store, at White Hall, Wis., was destroyed by fire on the 12th inst.

That the Foster Hardware Company have been organized at Huntington, W. Va., with a capital stock of $50,000. The incorporators are B. W. Foster, Charles Fussell, L. M. Sanford and D. E. Abbott of Huntington, and John Russell of Ashland, Ky.

That W. P. Lett has succeeded Stewart & Lett in the Hardware business at Riverside, Cal.

That Jansen Bros., Hardware dealers, Ritzville, Wash., have sold out to H. T. Jansen.

That Chas. L. Grace is now carrying on the Hardware business formerly conducted by S. C. Summers & Co., Stanton, Mich.

That Hackett & Hebard's stock of Hardware, Stoves, Guns, Implements, &c., was destroyed in a large fire in Augusta, Wis., on the 16th inst. The loss is estimated at $6500.

That H. D. Sheets, Lewis, Iowa, has put in a stock of Shelf Hardware in connection with his harness shop.

That the Hardware business formerly conducted by Sheldon Bliss, Constantine, Mich., will hereafter be carried on under the style of Bliss Hardware Company, with Arthur Bliss as manager.

That S. A. Maley has sold his interest in the new Hardware store at Rhodes, Iowa, to F. L. Mackey.

That Orr Bros., Murra, Iowa, have just completed an addition to their Hardware store.

That Owings & Stevens, Darlington, Mo., have purchased a two-thirds interest in the Hardware business formerly conducted by Adkisson, Bentley & Co., C. T. Adkisson retiring from the firm.

That the Gorham-Aid Hardware Company, West Plains, Mo., will build an addition to their establishment.

That the Hardware firm of Williams & Sumner, Bayard, Iowa, have dissolved partnership. Mr. Williams has taken the Hardware stock and Mr. Sumner the stock of harness.

That J. W. Delano, Red Wing, Minn., has sold his Hardware store to A. J. Meacham and Frank Meacham, who will take possession about the middle of April.

That Charles Stuart has purchased a half interest in the Hardware store of A. D. Barker, Grand Blanc, Mich., and will enter into partnership with him April 1. The business will be carried on under the style of Barker & Co.

That the firm of Anderson & Forton, Hardware merchants, Stoughton, Wis., has been dissolved by the retirement of O. O. Forton. The business will be continued by Mr. Anderson.

That the La Conner Hardware Company, La Conner, Wash., have dissolved, T. S. Hurd retiring and T. R. Hayton and A. I. Dunlap continuing under the firm name of Hayton & Dunlap.

That John Taylor's interest in the Hardware firm of Lefurge & Taylor, Ypsilanti, Mich., has been purchased by T. J. Green. The firm style will hereafter be Lefurge & Green.

That S. M. Scribner of Melrose, Mass., has purchased Mr. Burrell's interest in the Hardware business of Burrell & Swett, and the business will hereafter be conducted under the style of Swett & Scribner.

That the Hardware firm of Burget & Lewis, Great Barrington, Mass., have been converted into a corporation under the style of the Burget & Lewis Company. Mr. Lewis is president of the company and Mr. Burget is treasurer and manager. The capital of the company is $10,000.

Galvanized Sheet Iron.

We commend to the attention of those of our readers who are interested in buying and selling galvanized sheet iron a table of net prices published upon another page of this issue. It is known that the standard gauge for sheet iron was changed last year by act of Congress, and on the first of last July the revision came into effect. The new gauges are based on weights per square foot in ounces avoirdupois, varying by even or half ounces. Galvanized sheet iron is likewise gauged by weight, the black iron gange being used as a basis and 2½ ounces per square foot added for the corresponding galvanized sheet iron numbers. In the list presented elsewhere the discounts range from 65 per cent., which is below present prices, to 85 per cent., which is much above the present discount. The table covers all the gauges in common use —that is, starting with 10, 12, 14, 16 and 18, then by single numbers to and including No. 30. Referring to the page containing this table, it will be noticed that the top line gives the list price per pound, then ounces per square foot, next the decimal equivalents in pounds per square foot, and the fourth line, in heavier type, is the list price per square foot. Below are given the discounts, the prices being in cents. For each discount net prices are worked out per pound and per square foot for all the above mentioned gauge numbers. To facilitate reference heavy faced type is used for the per square foot discounts. Twenty-five discounts are given in all, so there are prices for variations of less than 1 per cent. in the discount.

Evening Classes.

As the season of evening class instruction draws to a close there must come to many a young man who has profited by it a clearer realization of his opportunity in life. He will see that what he is and what he may be depends almost entirely upon his own exertions. He appreciates more fully than ever before not only the pleasure of possessing knowledge, but perhaps even now has learned how it profiteth a man to be wise. But a man can no more acquire knowledge by a mere receptive process without exertion of his own than he can gain strength without exercise. Thanks to the generosity and the foresight of individuals and various organizations, there can now be obtained in almost any town or city of moderate size evening class instruction in at least the rudiments of an education, and that without expense to the pupil, while in the larger cities free courses may be attended in drawing, the higher mathematics, manual training and designing, and such other instruction may be obtained as will thoroughly equip an ordinary mechanic for a responsible position. Doubtless many a draftsman or head designer can trace his progress back to a humble beginning in an evening drawing class. But even this general instruction is being supplemented by more detailed courses in certain departments, either in day or evening classes. Such, for instance, is the proposed course in sheet metal pattern cutting at the Pratt Institute, Brooklyn, of special interest to the readers of this paper, in which it has already been announced. To a young man who has his evenings to himself there can be no reasonable excuse if he lacks a fair rudimentary education. It all depends upon his own determination and persistency.

Self-Education.

Even to the young man deprived of the advantages of evening class instruction there is still an opportunity to perfect himself by home study. True it is that such study is difficult, progress is far less rapid and there is much more excuse for failure than is the case when the student is subject to the encouraging influence of others studying with him under competent instruction. But on the other hand, once mastered, the subject is his by right of conquest who wins single handed. It is impressed on his mind as it could never be had the struggle been less severe. Success in home study is, to a large degree, measured by regularity and method in all that is done. One hardly appreciates the loss (if such it can be considered) of giving half an hour a day to study, and yet in a year—Sundays and holidays excepted —this foots up the equivalent of about 20 days of eight hours each. Enough time, it is evident, if taken in the aggregate to very considerably increase one's store of knowledge. It is related that John Tyndal's success began with his determination to devote all of his spare time to study, and so earnest was he in this effort that he arose for this purpose at five on the morning of the first day after he made this resolve and continued so to do for many years. One of the benefits of home study lies in the fact that it is generally impossible to proceed to more advanced study until that in hand has been mastered, so that there is a continued incentive to perfection in each day's work. Above all things the course of study should be clearly mapped out and persisted in. There should be no cursory reading, no skipping or slighting because the matter is not clear. There likewise should be no attempt to begin the course with studies too advanced. Arithmetic must be fully comprehended before algebra is attempted, geometry should be at least reasonably well understood before a course in drawing is entered upon, and to those who desire to study the languages English grammar is a first requisite. Books can be purchased at reasonable rates, and but few are required at a time by the home student, so that the real expense of his study need not be great.

Instruction by Correspondence.

As something between the evening class instruction and unaided individual home study there are gradually arising correspondence schools and courses of study conducted entirely by correspondence. The remarkable success of the Chautauqua circle in a line and by a method somewhat similar is evidence of the possibilities of an extension of the method. University extension is destined to do much along the higher lines of study, while less pretentious courses are likely to be presented to the mechanic and the artisan. Such a plan is that of the Correspondence School of Mechanics, which furnishes text books of its own preparation, conducts the instruction by mail and awards a diploma or certificate upon passage of the requisite examinations. While it is extremely difficult for a student under such a method to properly present in writing to the instructor the points that puzzle him, and perhaps as hard for him to understand the explanation that is written in reply, nevertheless there is, 1, a direct benefit in the necessity of clearly stating upon paper the existing difficulty ; 2, a consequent indirect instruction in English composition ; and, 3, an advantage in having the instructor's reply permanently recorded where it can be read and reread until the meaning is clear. Of course, such instruction by correspondence cannot be furnished without charge, but in the case of such schools or courses as are already in operation the expense

is by no means excessive. In fact, the cost of an education by any one of the three methods here presented should not, and to a determined young man will not, be a serious hindrance. If he is sufficiently resolute to attempt and persist in a course of study he will somehow, even by serious self denial in other things, set aside the means to accomplish the end he has in view. He will make of himself a better, a nobler, a wiser and a more capable man.

Not the Time for Strikes.

As mild weather resumes its sway, says *The Iron Age*, the strike season begins. It was much to hope that the bitter period of adversity through which the country passed last summer had permanently changed the attitude of labor leaders and implanted among their followers a spirit of quiet resignation to untoward circumstances. When factories were shut down on every side and thousands of willing workers were thrown out of employment in every manufacturing center, reductions in wages were accepted almost without a murmur by even the craftsmen who are ordinarily the most turbulent and uncontrollable. The times were then not only bad, but every one feared that they might be worse, and, besides, winter was at hand with its necessity for warm clothing, extra fuel and good food. Now, however, the chill winds have about ended, and with the advent of spring work is naturally much more plentiful. The prospect is not so cheerless as it was last fall. Therefore, latent discontent with reduced wage scales is beginning to crop out, and strikes are making their appearance in various localities and in different trades. It is a most unfortunate time for such troubles, as there has not been a sufficient revival in business to justify advances in wages, and in addition to this every strike now cuts down the purchasing power of the people, which needs to be kept up and built up as much as possible so as to help general business to emerge from the mire in which it has so long been floundering. Labor agitators who would precipitate trouble at a time like this are totally bereft of wisdom. But they and their following may to some extent be influenced by the false statements of reviving business which are now published for political purposes in great metropolitan journals. The newspaper which says, for instance, that the Illinois Steel Company have enough orders on hand to keep their South Chicago rail mill running night and day for two years does a very great deal toward stirring up unrest among workingmen. The statement is ridiculously incorrect, as every one connected with the iron trade knows or should know. And yet it has been copied all over the country, and has even been accepted as true by a trade journal which professes to have some connection with iron and steel interests. While we deprecate calamity howling, and believe that matters are mending instead of growing worse, yet business is in such condition that the precipitation of labor troubles on the large scale now threatened will give it a serious backset. Those who write for the public eye should confine themselves strictly to the truth. There is a serious responsibility on their shoulders.

We are informed that applications for sheet metal pattern cutting instruction have been coming in to Professor Richards, director of the Trade School of the Pratt Institute, Brooklyn, quite freely. If the number of candidates increases at all between now and next September, the starting of a class during the latter month will be assured.

Williamson Trade School.

The first commencement of the Williamson Free School of Mechanical Trades, Elwyn, Delaware County, Pa., was held on Monday, April 2, when diplomas were awarded to 46 graduates. The trades taught at the school, namely, bricklaying and plastering, carpentry, machine work, and pattern making, each contributed about an equal number of students to the total number graduating. The students were addressed by Governor Pattison of Pennsylvania, Mayor Stuart of Philadelphia, Hon. John Wanamaker, and other notabilities. President Schrigley of the school gave a very encouraging account of its progress and utility. All the buildings have now been completed and equipped, and yet there are now more available funds in the treasury of the school than there were at starting. The average age of the graduates was 19½ years.

News and Notes.

Governor Flower has signed a bill passed by the New York Legislature prohibiting the erection of bank buildings at a greater cost than 25 per cent. of the net surplus of the institution.

New Hampshire advices report a poor maple sugar crop.

Over 3000 applications are said to have been received for the prize of $50,000 offered by the Metropolitan Traction Company of New York for a system of street railroad power superior to the overhead trolley system and equally cheap of operation.

The decline of agriculture in England is becoming a serious question. Every year sees more and more land going out of cultivation. The decrease last year was 176,000 acres, and during the last 20 years nearly 2,000,000 acres have been abandoned.

The city of Detroit is to do its own lighting.

The *Journal of Railway Appliances* is of the opinion that iron car construction has taken permanent root in this country.

The River and Harbor bill which was reported to the House last week carries an appropriation for the fiscal year ending 1895 of about $9,500,000, which is $12,000,000 less than that for the current fiscal year and $30,000,000 less than the estimates submitted by the Government engineers.

Of the 55,768,000 bushels of grain exported from the port of New York during the year 1893, not one bushel was carried in an American vessel. The grain carrying trade is exclusively in the hands of foreigners.

A reorganization committee for the Atchison Railroad is in process of formation.

The battle ships "Iowa" and "Brooklyn," now under construction at the Cramps' shipyard, Philadelphia, will be ready for launching in the fall.

The statement that the Pennsylvania Railroad Company is interested in the North River Bridge project, to connect New York and Jersey City, is officially denied. One of the principal Pennsylvania officials is quoted as saying that when the road enters New York it will be underground, not overhead.

Views of a Welsh Tin Plate Manufacturer.

E. R. Daniel, a Welsh tin plate manufacturer, has recently returned home from a business visit to the United States. His observations while in this country have led him to the conviction that the Wilson bill will pass the Senate in the same form in which it passed the House of Representatives, and that afterward the Welsh tin plate industry will revive and the American will languish. The grounds for this confidence he gives in an interesting interview lately published in the *Western Mail* of Cardiff. Assuming that a $1\frac{2}{10}$ cents duty is to be imposed, he remarks as follows: "There is no doubt in my mind that when it does the Americans will not be able to compete with us in the manufacture of tin plates. They don't economize in material so carefully as we do, and so they can't put the finish on the article for our price, especially at the high wage rates prevailing. I called at a little place near Pittsburgh where they were turning out 4500 boxes of plates weekly, 1500 of which they coated there and the rest sent elsewhere. I got it from the owners themselves that they would not be able to make tin plates profitably if the Wilson bill passed. And so at Taylor's works, Philadelphia, and other places. There seemed to be but one opinion on the point, and that the same as I have stated." Being asked whether there really are tin plate works to be found in America, Mr. Daniel replied: "Oh! yes, a few; and one or two very good ones, I can tell you." The trade in this country he reports to be as bad as bad can be. In metals he found no stocks anywhere; every one working their last pound, and only buying from hand to mouth. From this he infers that in a couple of months after the passage of the tariff bill better things will be seen in Wales.. "Consumption out there," said he, "has not ceased, yet our Welsh works have been idle. The canning season will be upon them directly, and what are they to do but take our plates?

"And another thing," said Mr. Daniel in conclusion, "the Americans, you know, have been exporting very much more than they have been importing of late, and they can afford to send us a few orders without injuring their balance of trade."

Dispatches from all parts of the country indicate that the severe cold of the last few days has done great damage to budding fruit trees and growing crops.

THE LETTER BOX.

Loss of Steam Pressure.

From H. B. C., *St. Louis*.—In our plant here we have two boilers, capacity 30 and 60 horse-power, with 4-inch main reduced to 3 inch, running about 100 feet and tapped by ¾ inch pipes running to our jacket kettles. The feed pipes on the kettles are ¾ inch and the same size return. The returns empty into steam traps which stand boiler pressure. We have steam gauges on our kettles, and while our steam gauge on our boiler shows a pressure of 80 pounds and on the main 2 feet from the kettles shows 75 pounds, the gauge on the kettles shows but 20 pounds. We have examined the pipes and know they are perfectly clear, and do not understand why we cannot get a pressure on the kettles within a few pounds of the main. We use copper kettles, steam jacketed, with a capacity of from 1 to 4 barrels. We have had some of our steam experts here pass on the matter, and they do not seem to understand why we cannot get the pressure, so we concluded to submit the problem to *The Metal Worker* and its readers for solution. We would state that in our other factory, from which we recently moved, our main was a 2-inch one from 80 horse-power boilers, and the gauge on our kettles showed but 10 pounds lower pressure than the gauge on our boilers. All our kettles are within 2 feet on the main and the valves are all new Jenkins valves, and there is no leak that we can see in any way in the main.

Note.—This problem should elicit some interesting opinions from our readers. The trouble is probably due to some defect in the system which has been overlooked. A number of experts have been consulted and none can give a satisfactory explanation, but all agree that there is something that has been overlooked which an experienced man would soon detect. The employment of such a man will be the best way to secure service, and in the mean time some suggestions may be received. We hope our correspondent will describe what caused the trouble when it is found.

A Question in Lead Burning.

From H. D. T., *Scranton, Pa.*—Please inform me through *The Metal Worker* what acid or preparation it is that is sometimes used in lead burning.

Answer.—Speaking of acids in connection with lead burning, there comes to mind the dilute sulphuric acid that is used in generating the hydrogen gas. Our correspondent, however, evidently means something else. We have submitted this matter to H. J. Bailey, Pittsburgh, Pa., a well-known expert in lead burning, and from his reply we quote as follows: "The acid or solution that you ask about is a solution of the double chlorides of ammonia and zinc. This is the king flux solution. Some lead burners use the following solution: Into muriatic acid put shreds or clippings of sheet zinc and let stand until all bubbling ceases. Some add 1 ounce of sal ammoniac to each pound of this solution. A good lead burner, however, needs no flux. He cleans his lead edges with the shave hook and proceeds to unite or burn the edges together by means of the non-oxidizing flame. The acid he inquires about is used only where the lead burner has burnt the lead by the oxidizing flame, which would not have happened if he had understood the nature of the flame he was working with."

Rosining Roof Seams.

From J. J., *Hohokus, N. J.*—Seeing the different letters in *The Metal Worker* about roofing, I contribute a description

Rosining Roof Seams.

and a sketch of an apparatus and method I use in rosining seams for flat seam roofing. After the seams are all flattened down with the mallet, I take the fine rosin which accumulates in the barrel and put it in a funnel shaped device with a handle of 1¼-inch iron and about 2 feet long and spread it on the seams. The funnel part is about 4 inches in diameter at the large end and $\frac{3}{16}$ inch at the bottom, and is about 6 inches long. When this is filled with rosin I put the end with the small hole on the edge of the seam and run a hot copper into the fine rosin, which melts it, and it runs out as the device is drawn along the seam, leaving the seam all ready for the application of the hot copper and solder.

Trouble With Solder.

From A. D. E., *New York*.—Having experienced some trouble in getting a good wiping solder, I bought some tin and lead from a house that is reliable in furnishing pure articles, and mixed 4 pounds of tin and 6 pounds of lead and made up 100 pounds of solder. With this solder, try as I may, I cannot get a bright joint, no matter how hot the solder or how quick I wipe it. Will you kindly answer me through *The Metal Worker* if there is a certain brand of tin or lead required to make bright wiped joints?

Answer.—We think our correspondent's trouble is due to some impurity rather than to the brand of goods used. Some plumbers always use Banca tin and are careful to get pure lead, never using new or old lead pipe, though sheet lead is not objected to. By sprinkling sulphur over a pot of solder heated red hot and stirring it in thoroughly the solder can be cleaned and then tried on a joint, when if it turns out bright a sufficient proof may be had of the impurity. Then by adding the tin and good sheet lead the metals causing the trouble can be discovered.

Poportions of Fire Places.

From F. A. F., *Helena, Mont.*—Will some one please give me, through the columns of the paper, the proper depth and hight for fire places in which andirons are to be employed? I desire to know what should be the depth and hight of fire places 3 feet wide, 3 feet 6 inches wide, 4 feet wide, 4 feet 6 inches wide and 5 feet wide. There are very few fire places in this town which give satisfaction, as most of them smoke, and I think the fault is in the depth and hight of the fire place when compared with its width.

Note.—We referred the above inquiry to one of the leading grate manufacturers in this city, who furnishes the following touching the points raised by our correspondent: The proper dimensions of a fire place depend upon the size of the flue and its form. Usually the fire place is made 30 inches wide, 30 inches high and 12 inches deep, in connection with a flue 8 x 8 inches. A safe rule for regulating the size of the flue in its relation to the fire place is to make its area one-eighth that of the product of the width and hight of the fire place in inches. Thus a fire place 4 feet wide by 4 feet high, giving an area of 2304 inches, should have a flue area of 288 inches, or about 17 inches square. This, however, is only a general rule, applicable more particularly to high fire place openings. Smaller fire places, as the 30 x 30 inches, will work well with a flue area less than one-tenth of the area of the fire place opening. A matter not less important than the size of the flue is its shape where it joins the fire place. No flue is a good one which does not slope at an angle of 45° from the horizontal line. While the smoke is hot it should reach the narrowest or smallest part of the flue, and that point should not be over 20 to 24 inches above the top of the fire place. There would be few complaints of smoky fire places if builders gave proper regard to the shape of

the flues, and never was this caution more necessary than it is at present, when corner fire places are so much in vogue. Some masons think that if they make a flue very large all danger of bad draft may be avoided, but this is a great error. There is as great danger in making a flue too large as in making it too small. A flue should be no larger than is necessary to carry off the greatest volume of smoke that is made by the fire. If larger, eddies or counter currents are formed which greatly impair the draft.

The Capable Man.

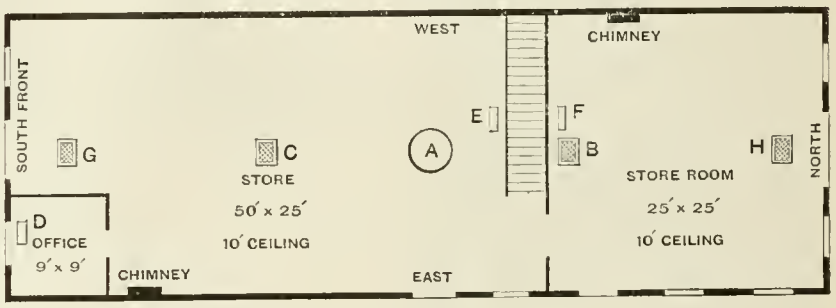
From MECHANIC.—In an article in *The Metal Worker* of March 10, page 27, which was reprinted from the *Clay Worker*, I think some erroneous statements were made respecting a capable man being seldom out of a job even in hard times. I have worked in several shops, and talked with a great many in different callings who have worked under various foremen, and all the evidence I can get goes to show that the survival of the fittest is not the rule, but rather the second or third beat retain their positions. The average foreman is afraid to keep a man who is competent or perhaps a better mechanic than himself for fear of losing his position, while by keeping the second-class man who is not able to turn out so much or so fine work, he renders his position more secure. His star appears all the brighter when viewed from the manager's office from the mere fact of being surrounded by such dim lights. I will warrant that many readers of your paper have left good positions simply because the foreman did not feel at ease when they were working, and so took the first opportunity to have them dispensed with. Any person who has read history knows perfectly well that it was not the best man who occupied positions of trust in all cases. In many instances a good man may get a fair start, but just so soon as he begins to crowd those at the top, off goes his head. If the manager will send some one around among the men, now and then, to find out what the mechanics think, men would remain longer in the same shop. Another test is to give the foreman an extra difficult piece of work, then watch and see if he gives it to the man who keeps steadily employed or to the man whom he lays off. It always seemed strange to me to see the foreman give one man first class work to do during the busy season and another nothing but common work (who couldn't do a smooth job to save his life), but as soon as trade slackened the good mechanic was laid off.

Note.—We print our correspondent's letter, not because we agree with him, but simply to illustrate the feeling of a certain class of men. While all that he says is true in some and perhaps many cases, it is not the universal rule. There are many small minded, jealous foremen, undoubtedly, but we believe that there are more foremen who are superior to these petty notions. Very often a first-class workman fails to keep a steady job, simply by reason of some personal peculiarity—an offensive manner, or a spirit of criticism, or some trick or other that makes him a disagreeable companion, though his work may not have any defect. We suggest to our correspondent that he bear this fact in mind as a possible explanation of some of the cases where a competent man is laid off and not ascribe it entirely to the foreman's jealousy.

Wants Suggestions on Heating.

From J. P., *Millbrook, N. Y.*—I have a 271 Fuller & Warren Company combination warm air and hot water heater, which I want to use to heat the store shown by the plan and would like suggestions on putting it in so as to use both kinds of heat successfully. It is a two story brick building, to be used as a hardware store, and I want to heat the first floor comfortably, and the second floor, which is all in one room, I only want to take the chill off. The office partition is only 6 feet high and the ceilings are 10 feet. There is a cellar under the whole building. Where should the heater be set and where should the registers and radiators be placed?

Note.—No doubt different opinions exist as to what is best in this case, and we hope they will be expressed in *The Metal Worker*. A good location for the heater will be 6 feet south of the stairs, at the center of the building, at A. A 14-inch pipe should be run to a 14 x 20 register, at B, in the back storeroom, and a 16 inch pipe should run 10 feet toward the front of the store, to a 16 x 20 register, at C. A 1-inch pipe should be run to a radiator containing 40 square feet of surface, at D, and a 1¼-inch pipe should be run to a point below the radiator E, located near the stairs on the upper floor. At this point a 1¼ inch riser should be taken to the radiator, and the main reduced to 1¼ inch and continued until it rises to the radiator, at F, on the other side of the stairs on the second floor. The second story has 18,750 cubic feet of space, and as a moderate temperature will be satisfactory if 1 square foot of surface is used for every 90 cubic feet of space, 100 square feet of surface exposed in each of the radiators will be ample. The returns from the radiators should be run the same as the flow pipes and should connect at the return in the heater. All of the water pipes should have a pitch from the heater, without any dips, to secure a good flow through the system. All the radiators should have air valves at the top. An expansion tank should be located near the ceiling on the second floor and be connected by a 1-inch pipe with the return pipe in the basement at the most convenient point. As the store will probably have a sufficient change of air through the opening and closing of the doors, the furnace may take its supply from the basement, if it is kept clean, and a circulation can be kept up by placing a 14 x 20 register in the floor, at G, in the front store, and one at H in the back store. As there are two chimneys, one can be used as ventilating shaft if desired, using that having the better draft for a smoke flue.



Wants Suggestions on Heating.

Wants a Sewer Trap.

From J. L., *Danville, Pa.*—Please give me some information in *The Metal Worker* about the trapping of sewers in city outlets. We have an 18-inch terra cotta sewer here and have taken several 15-inch outlets for surface water at the gutters. When the water in the river gets low the end of the sewer is exposed and a disagreeable smell comes from the street outlet. I cannot get a 15 inch terra cotta trap and would like to know some method of trapping that would overcome the trouble.

Answer.—Terra cotta running traps 15 inches in diameter can be bought from several different makers, but are not carried in stock and two weeks would be required to fill an order. They are preferable to what are known as mason's traps, as they are likely to be flushed clean when the full bore of the pipe is filled with water, and consequently do not fill up with dirt so readily. If a mason's trap is to be used, some trouble should be taken in building it to have the turns easy. It consists of a chamber having dimensions twice those of the inlet and outlet in depth and length. Both the inlet and outlet should run from the side of the chamber as near the top as possible. In building the trap a stone or iron partition should extend down from the top of the chamber two or three inches below the bottom of the inlet and outlet, and should be placed across the chamber midway between the openings. The inlet may enter the top of the chamber on the inside of the partition, otherwise a manhole must be provided for cleaning. Care should be taken to have the chamber and the partition separating the two parts made air tight;

then, when water fills the lower part of the chamber and the partition extends down into it, the sewer air cannot escape to the street outlet.

Roofing Material Wanted.

From M. H. R, *Winnipeg, Manitoba.*—Your Letter Box department has solved so many practical difficulties that I venture to ask your advice with respect to roofing material suitable for this climate, which, as you are probably aware, is, on the whole, very dry, but subject to occasional wet intervals, and with a variation between lowest winter and highest summer temperature of about 150° F. (from 50° below zero to 100° in the shade). Different materials have been tried, but all are more or less defective. What seems to be wanted is some material impervious to wet, and which will not expand or contract as between hot and cold and wet and dry seasons. Ordinary tin or metal roofing expands and contracts so much that even if at first properly laid down and fitted, leak holes soon appear and give trouble, more particularly during the mild spells in winter when there is snow on the roof. I trust that some of your readers can suggest a remedy for the trouble named.

Note.—It is an interesting topic that our correspondent suggests for discussion, and we would like to have opinions from practical readers that we might print them for his assistance. Two methods of meeting the problem are either to use a metallic roof and so lay it that the great expansion and contraction will be provided for, or else make use of some material which does not vary so much between the limits of temperature mentioned. Trouble with most of the softer materials, if we may so classify them, is that they are not so enduring, as a rule, as the metallic roofs; but on the other hand, it should be borne in mind that the climate of Winnipeg is very dry and is therefore not so destructive as the climate elsewhere and near the seaboard. Our correspondent gives a limit of temperature from 50° below zero to 100° in the shade. But it must not be forgotten that the roof is exposed to the sun temperature, which, with the thermometer at 100° in the shade, would be very likely to register up to 130° or 140°.

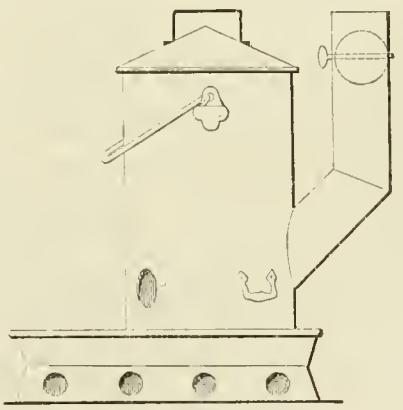
Should be Brazed.

From A TINSMITH, *New York.*—I wish to get some information through *The Metal Worker* about a job that is giving me trouble. I am putting brass blocks on steel heel plates. The plates are ground bright and I tin them thoroughly, as well as the brass blocks, and join them while they are hot by holding over a fire, but when they cool they come apart and all of the solder is on the brass block and the steel plate is as clean as it was before I tinned it. I use half and half solder, but cannot use acid, as it would make the plates rust. The plates are well coated with solder and I would like to know why the solder does not stick and what I can use instead of acid. I have used pure block tin, but with no better success.

Answer.—If the articles are thoroughly washed in clean water after tinning there will be no acid left to produce rust, and an acid flux will secure a stronger union of the two parts and may be sufficient. If considerable strength is desired brazing will prove more satisfactory and is done by cleaning the surfaces to be united and using borax as a flux and hard solder of a composition that will melt before either of the parts are melted. Usually a red heat is required for fusing. The fusion may be effected at a lower temperature by using different alloys or proportions. One part copper and one part zinc is given by a recent book as a generally used proportion. The alloy is cast in ingots, which are heated red and hammered, and at the right temperature it will granulate in lustrous yellow particles, when it is ready to be used. A more readily fusible composition is given as 44 parts copper, 49.9 parts zinc, 3.3 parts tin and 1.2 parts lead. If the brass blocks and steel heel plates are united by these solders the trouble reported will be overcome

Roofing Fire Pots.

From J. D. G., *Boseman, Mon.*—In response to the request of "F. W. S." in *The Metal Worker*, March 3, I submit a sketch of my roofing fire pot. It is 16 inches high, 9 inches in diameter and sets on a 10 x 16 inch base 1 inch high, with a 1-inch rim around the top. The base is ventilated by several ½-inch holes around the bottom, and both it and the rim are wired to give strength. The rim is to catch the coals that are drawn out with the coppers. A 3-inch pipe connects at the bottom and runs up to the top with a damper in it. The front is lined with heavy sheet iron and is riveted around the holes. The top has a tight lift off cover.



Roofing Fire Pots.

Left Handed Tinners.

From W. S. L.—Although the question has been pretty well exhausted, I nevertheless would like to say a few words on this topic. When I was young I was very right handed, but took it into my head that it would be convenient to use both or either hand, and by some practice and perseverance I became handy with both. I had an apprentice some years ago who was left handed, and although awkward at first, in a short time he could use one hand as well as the other, which gave him an advantage in shop work. I believe it would be a benefit to a great many men if when young they were trained to use both the hands at all kinds of work. There might be an exercise in the schools for the purpose of training in the use of both hands, if only for half an hour a day.

Small Air Bound Pipes.

From HELIOS. — Referring to the letter of "E. J. S.," page 30 of *The Metal Worker* of March 17, will say that if "E. J. S." will take a ½-inch pipe connection from the horizontal pipe over the door and run it up and over the tank on the second floor, leaving the end open, all the air can pass out when the boiler is filled with water. If the water in the boiler at any time should reach the boiling point, all the steam will escape from the pipe over the tank. This connection will stop all the rumbling noise and allow a free circulation of the water. Would advise taking out all the ½-inch pipe and make it ¾ inch inside diameter with a ½ inch air pipe over tank.

Hot Water from Cold Faucet.

From HELIOS.—Referring to the letter of "L. J. P.," page 32 of *The Metal Worker* of March 17, will say that by placing a swing check valve in horizontal cold water pipe over the boiler, with the valve set to close when the faucet is opened over the sink, it will stop the hot water from leaving the boiler through the cold water pipe. If a check valve is placed in the cold water supply pipe to a boiler, there will have to be connected to the hot water pipe a water relief valve. The waste from the relief valve can be connected and discharged over the sink. There will also have to be placed on the boiler a vacuum valve to allow the air to enter the boiler and prevent the collapsing of the boiler.

Miter Patterns.

From SUBSCRIBER.—I would like to be informed how to obtain the patterns for a square return miter, an octagonal miter, and for a butt miter against a curved surface.

Answer.—Referring to "The Metal Worker Pattern Book," the answer to the first question can be found on page 153, to the second on page 211, and to the third on page 155.

Cleaning Zinc.

From T. G. S., *Genoa, Ill.*—Will *The Metal Worker* or some of its readers give me a receipt for cleaning and polishing zinc?

Answer.—A well-known receipt book says zinc is generally mechanically pickled by scouring with sand and powdered pumice. The bath used for brass is also very effectual; it is composed of one part of ordinary nitric acid and one part of sulphuric acid and must be washed off with clean water. To larger articles which cannot be dipped in the bath of acid and water apply a solution of potassium-ammonium tartrate thickened with sufficient clay to form a fluid paste. After a few hours rub the article with a brush dipped occasionally into fine sand moistened with the pickle, then polish with powdered charcoal or Vienna lime.

Fuel for Furnaces.

From FURNACE DOCTOR, *Rochester, N. Y.*—The high price of fuel makes every one desirious of using that which is cheapest. After 15 consecutive years' experience in caring for furnaces, sometimes as many as 20 at a time, I feel that I am in position to express an opinion on the relative values of different kinds of fuel. To heat a house cheaply the furnace should be very large in proportion to the size of the house to be warmed. It should be filled with fuel and the draft closed, thereby insuring more nearly perfect combustion. In giving my opinion about fuels I will first relate my individual experience. The house in which I live is a new one, built three years ago, two stories, brick, three rooms and hall below and three rooms and bathroom above. The first winter I used gas coke for heating with a furnace of ample size. I paid 5½ cents per bushel for coke, and it took 250 bushels to carry me through the season, costing $28.60 in all. Coal at the time was $4.50 a ton, and as I afterward learned it would have required 9 tons, which would have amounted to $40.50, making a saving of $11.90 for that year. The next winter I used the same amount, 250 bushels, at a cost of $37.40, the price being raised twice. The price of coal that year was $5 a ton, which for 9 tons would have amounted to $45. Again, you see, I made a liberal saving. The present winter gas coke has been 8 cents per bushel and so last fall I decided to try coal at $5 a ton. Before the season closes I shall have used just about 9 tons. By using coke at 8 cents a bushel there would have been a slight saving in money and I would have had much more satisfactory results so far as heating is concerned, for, on account of a weak draft in the chimney, the coal takes a long time to get burning, while coke burns up readily, and when the draft is closed it holds the fire well.

In addition to my own experience I have a good deal to do with other houses, of which I will send some account. In large houses I burn from 15 to 17 tons of coal a season, and I find that the Pennsylvania coke, prepared expressly for fuel, shipped to this market, and sold at present at $4 a ton (coal now being $4 25) would do a little more work, or, rather, last a trifle longer, ton for ton, and at the same time make a vastly better fire than coal. As I am not in the interest of any coal dealer, but work for the interests of my patrons, I always advise them to use coke, and it has been the means of saving them many dollars. Three winters ago I was called to take care of a steam heater in the residence of a physician, who had been using coal at the rate of 2 tons in about 25 days. When I took the furnace the coal bin had just been filled up, and my experience was about the same. I then advised the use of Pennsylvania coke, and the result was, at $1.25 per ton less cost than coal, it lasted about three times longer. From that day to the present I have used no more coal in that furnace. As spring comes on and the weather gets warmer I have used gas coke and find for a very low pressure of steam that it has been a still further saving. Just at present I am using a small sized Pennsylvania coke, and find for raising steam it equals gas coke in economy. I will give a third example to illustrate what has been my experience. For the past eight years I have had charge of a furnace which uses 17 tons of coal per season. After a while I said to the householder that coal was dear, and advised the use of coke. I put in 200 bushels of gas coke at 6½ cents a bushel, making $13, which lasted until nearly Christmas. Then 7 tons of Pennsylvania coke at $3.75 a ton, amounting to $26 25. When that was used up mild weather had again arrived, and 100 bushels of gas coke, costing $6 50, carried the furnace through the season, the total cost being $45.75, against 17 tons of coal, which would have cost at $5 a ton $85, thus saving $39.25. I have used coke in that furnace ever since. I am just now taking care of 12 furnaces, and in only three am I using coal. To summarize very briefly, I find coke as a fuel for heating to be much the cheaper when used judiciously. In mild weather use gas coke, and in more severe weather Pennsylvania coke.

Note.—This letter from our correspondent is particularly interesting, as it deals with a very important matter—namely, the cost of fuel for warming houses. We wish our readers would take this occasion to tell us what experience they may have had with other fuel in comparison with coal.

Will Syphon Work?

From P. & L., *Woodstown, N. J.*—Wishing to syphon water out of a well 20 feet deep, would like to know from *The Metal Worker* or its readers if a ¾ inch pipe about 200 feet long will do the work, or will a larger pipe be necessary? The fall is sufficient and the length is mentioned that the conditions may be understood. The water is to be carried down a hill from a barn.

Note.—In *The Metal Worker* a few years back a correspondent stated that he had laid 1540 feet of 1-inch galvanized iron pipe from a brook to a tank, over a hill 29 feet high, and was able to fill the tank, which held 1200 gallons, in four hours. This will give our correspondent some practical information, but we should be glad to hear from others on the subject.

Swelled Boiler Piping.

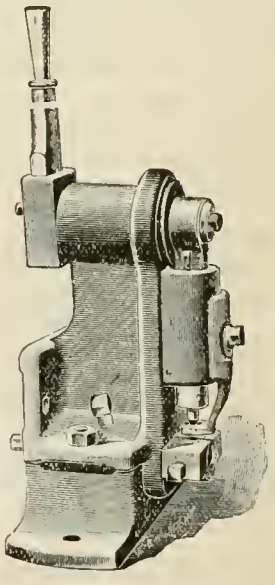
From E. H., *Nyack.*—A number of years ago I was called upon to repair the hot water pipe from a water back to a boiler. I found the boiler to have an open top with loose cover. Into this boiler the water was pumped as it became empty. The pipe close to the joint where the heavy lead pipe was wiped on the brass nipple at the side of the boiler was swelled to fully double the size of the other pipe, and had opened just enough to make a very small leak. The owner told me it had done so before, and wished me to make a new joint. I accordingly repaired it, but suggested that probably only an iron pipe would be a permanent remedy. About two weeks after I was called to replace the lead pipe with iron, as it had again given out. It has now been in use about five years with no further trouble. I would like to know if this is a common occurrence with such boilers, or is it owing to some local circumstance in this case?

Last fall I was called for the first time to a boiler which was supplied by pressure, not very heavy. In this case the lead pipe from water back to boiler had been swelled out of all proportion and been repeatedly mended next to the water back connection. It was leaking and I mended it as it had been mended before. In this case the break was through the solder, which seemed to have been almost as thick as the pipe. In a few weeks' time I replaced this with iron pipe, as another leak showed itself. We have had no further trouble. One more case was somewhat similar, only in this the pipe gave out next the boiler, and after several times repairing I substituted iron pipe, which remedied the difficulty. These troubles all doubtless arise from imperfect circulation, but why should they act so differently? I thought it might come from the boiler tube being so short that the cold water is discharged so close to the inlet for hot water as to cause it to damage this pipe every time. If such is the fact it becomes a very important matter to see that this tube extends well toward the bottom of the boiler.

Answer.—The swelling of the return pipe to the boiler is a quite common occurrence, and happens when the water back has a large heating capacity and when the water pressure is very light, as is stated in the cases reported. It is not due to the tube in the boiler or any unusual local condition. In *The Metal Worker*, March 17, an illustration and explanation of the trouble is given in the article entitled "Water Hammer and Boiler Connections."

Hand Power Scroll Punch

This tool, made by the W. & S. Hydraulic Machinery Works, 204 East Forty-third street, New York, is designed for the use of those who have to punch holes through small scroll bends. In order to obtain the greatest stiffness with small size the dies are located in the ends of a tool steel bar passing through the body of the machine. The bar is 1 inch in diameter at one end and is flattened to a larger circle at the other, and the centers of the dies are ⅝ inch from the end of the bar. A small table for punching flat iron is shown in position attached to die bar. The punch, as shown, is to be bolted down to the bench, but it can be detached and bolted to a post if desired. There is also a special projection for holding it in a vise. The lever is easily removed, as it slips into a socket, as shown. The tool and stand weigh 60 pounds.



Hand Power Scroll Punch.

NET PRICE OF GALVANIZED SHEET IRON.

The table printed below gives the net price of Galvanized Sheet Iron of the gauges in common use at discounts from 65 per cent. to 85 per cent. from the present list. The gauges, based on weights, are according to the United States standard which came into effect July 1, 1893, the galvanized sheets being 2½ oz. per square foot heavier than the black iron of the same number.

STEAM AND HOT WATER.

Heating Coils in Furnaces.

The following interesting letter comes from a correspondent in response to a request for the rule he used for determining the size of a coil to be placed in a hot air furnace for heating, by means of radiatiors, rooms that were difficult to heat with hot air:

I have had no experience in the making or installation of hot air furnaces, therefore cannot contribute anything of interest on that subject. I know that the difficulty of heating diatant rooms prevails to a considerable extent, as I hear many complainta and am frequently called upon to remove the cause, and in many instances have resorted to the coil in the furnace and radiators. I have alwaya been successful in overcoming the trouble, but as to giving any reliable rule by which to calculate the amount of heating surface or coil necessary in the furnace, I am afraid I will have to give it up. The conditions vary so much in each case where I have been called that I do not think it possible to give or apply any rule to them. This is one of the many things that one man cannot tell another. The best I can do is to describe just what I did in a peculiar case, and perhaps a rule may be evolved from that which may be of some use.

About 15 years ago I was called to a large residence where there waa a conservatory in the southeast corner of the house; one side, end and roof were of glass, with the side and slant roof facing toward the east. When the wind blew from the east they could not keep that part of the house warm; in fact, the plants would freeze even in moderately cold weather. The furnacemen did all they could, but did not help matters any. The furnace was a large one and was located about 20 feet away from the conservatory. I made a coil of 2 inch pipe and put it inside the fire pot, as shown in the illustration. It was put in in such a manner as not to interfere with the firing process, and to have 9 feet of 2 inch pipe inside the fire pot and directly over the fire and on a level with the top of the fire door. The next thing was to locate the required amount of heating surface in the room to be heated, which was 14 feet long, 7 feet wide and 6 feet 6 inches high. The shape of roof is shown in the cut. When I came to discuss this with the lady of the house, I met the first difficulty. Would she like a pipe coil around the outside walls, put up with return bends and neatly bronzed?

"Oh, no. It would spoil her shelves and burn her plants, and it would look too much like a factory; would not have that at all."

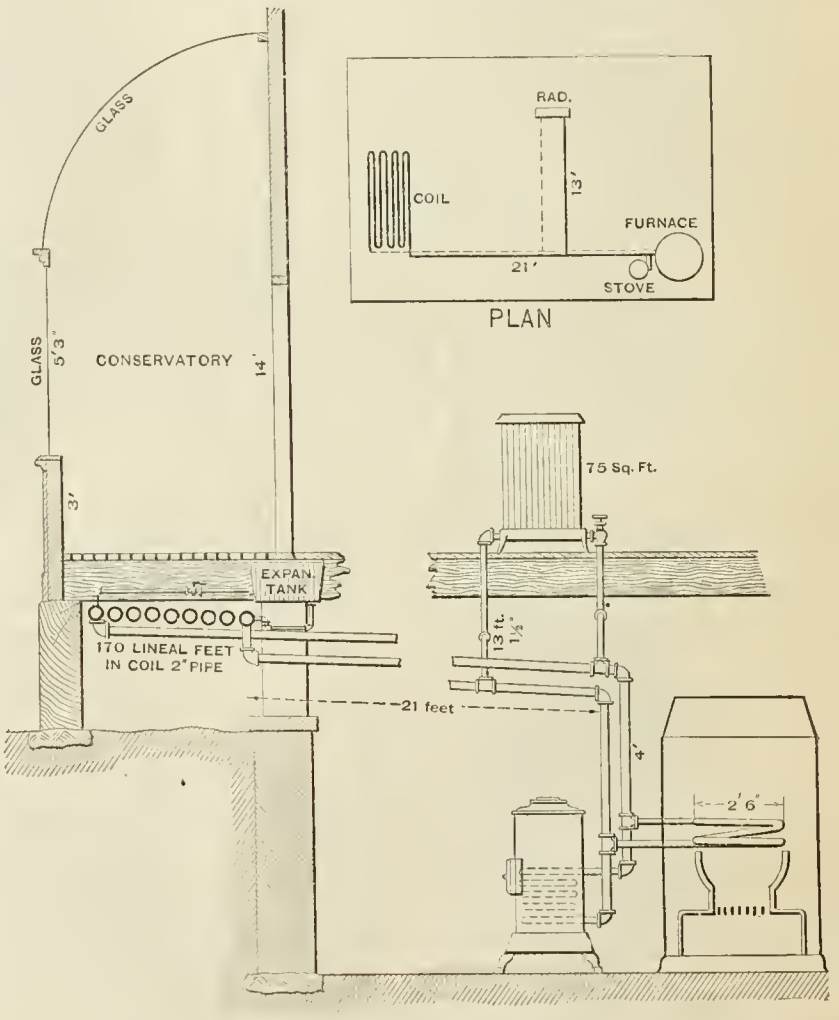
"Then, would a box coil answer, with an ornamental screen and marble top, if necessary?"

"No; could not spare the room."

"Well, then, I am afraid I will have to give it up."

"But you said you could warm this room—what do you mean making all this trouble? If you cannot do it no further argument is necessary."

I went into the cellar and found a window opening into a space about 2½ feet deep under the conservatory floor. I made a flat or gridiron coil, containing 171 lineal feet 2-inch pipe and suspended it from the bottom of the floor joists, giving it an incline sideways, so as to have each pipe a little higher than the one next to it, but kept them level lengthwise. I connected it to the coil in the furnace, putting a drain off cock at the lowest point: I then had the greater part of the floor in the middle of the room taken up, without disturbing the shelves, and relaid it with narrow strips, with ¼ inch of open space between them. The space between two of the joists I lined with copper for an expansion tank, as I could not put it above the floor, then made a connection from the tank to the return pipe, as shown, putting a trap in it purposely to prevent the tank from getting too hot. When I had that fixed it occurred to me, as such things will pop up when one is on the lookout for them, that some evaporation would be desirable in a room where plants were growing and in house heated by hot air, but this must be made without steam. I therefore made a connection with ½-inch pipe from the highest point of the coil to the tank, 3 inches from the bottom, with a stop cock. This answered two purposes; it relieved the coil of air and caused a circulation between the tank and the coil, which was completely under control, by means of which the water in the tank could be kept just hot enough to evaporate freely, but not make any steam. When the fire was started the arrangement worked very nicely, but I found that the window in the wall between the cellar and the space under the conservatory played a very important part in the apparatus. When kept shut and the fire lively the water in the tank showed an inclination to leave it, and I knew that if it should start it would come out like a Yellowstone Park geyser on a small scale, and if the lady of the house happened to be around she would dismiss us and the heater pretty quick. I left the window open and that pacified the tank. I had a loose cover put on the tank, so that if the geyser did play it would do no harm, and took the window in the cellar out altogether and left the thing to take care of itself.



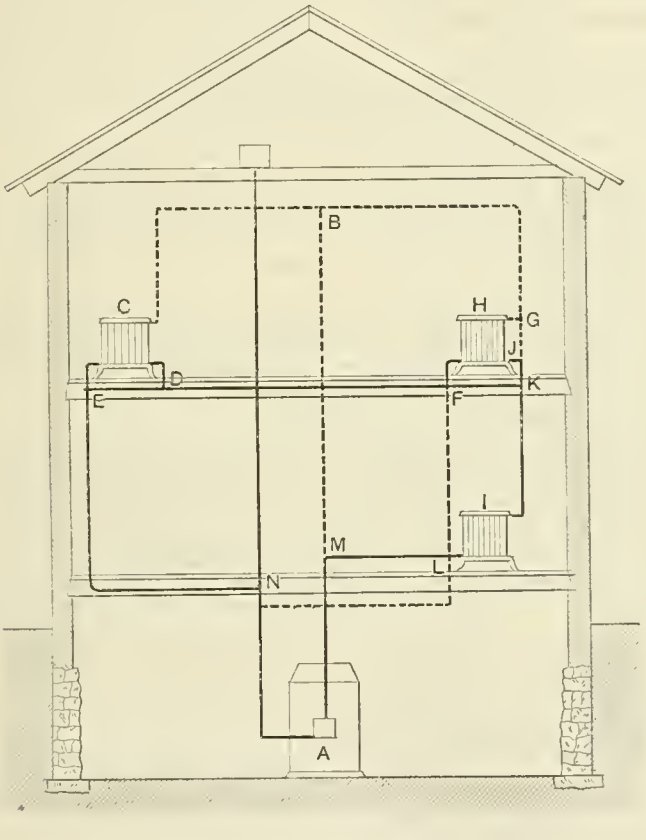
Heating Coils in Furnaces.

Thia condition of things allowed the cellar air to enter the house through the large door between the conservatory and the sitting room, which was always open, and this was not right; but there was no help, as the furnace got most of its air supply from the cellar, which was clean and dry (that is another peculiarity about cranky women—they will keep things clean). The lady of the house was getting very uneasy about the time it was taking, also the disturbance, and didn't have much confidence in the thing anyway, so I concluded I had better leave, as I did not have much confidence myself. I was afraid of that geyser, but I heard nothing about it until the end of the year, when I met the lady's husband on the street, and he told me as he passed that the heater worked like a charm. I was not quite sure he meant what he said, so I concluded I would settle the point by presenting my bill for the job, and if there was anything wrong I would certainly find it out then. As soon as I entered his office he began to tell what a nice heating arrangement I had put in for him, how long he had tried, and how much money he had spent in trying to warm that side of the house. "It gave him pleasure to pay the bill." Conjure in your mind, if you can, the feeling of a plumber at being spoken to in that way when he presents his bill. It was almost too much for me, and I was not sure but it was sarcasm, until a glance at the check he was making convinced me that it was all right, especially when I remembered that previously he used to do some vigorous kicking. I heard nothing more until three years after. When the natural gas was introduced they put the gas in the furnace without my knowing it. Then for the first time the geyser began to play, proving beyond a doubt that what was just right for coal was all wrong for gas. Of course I had to go and fix it, as they could not possibly get along without it. Some time previous to this they had converted a small room adjoining the sitting room into a toilet room, which they wanted to have heated, and I put a 75-foot radiator in the toilet room (the lady of the house was now willing that I should do as I pleased) and connected it up, as shown, without making any change in the former arrangement; this equalized things again, and they went all right. The next winter they wanted to go away for several months, and did not want to leave the furnace at work, but did not want to have the flowers frozen. I made a small heater by making a spiral coil 25 lineal feet out of 1-inch pipe and put it inside of a sheet iron cylinder, and set it on the base of an old stove, and fitted a gas burner inside of it, and limited the supply of gas to just enough to raise the temperature of the water to 190°.

It has done good service ever since, without any trouble whatever. When you come to see so large a proportion of radiation and so small a portion of heating surface, it may conflict with the rules for calculating the amount of heating surface; but we must bear in mind that every inch of the coil is exposed to the hottest part of the fire, with the flame acting directly on it, and is much more powerful than the average heating surface to be found in boilers and other forms of heaters taken as a whole. It is an old saying that a man's faults travel much faster than his virtues; but give the virtues a good start and they will leave faults in the rear.

After the above job was completed it was spoken of around town, and in a short time I had more of that kind of work than I could attend to. A large portion of it I could not do, even if I had had time, as my customers appeared to think there should be no limit to the thing, one man wanting a chicken house that stood about 50 feet from and 15 feet below the kitchen heated from the water back in the kitchen stove, and thought it strange that I did not want to do it. If this experience will be of any use in forming a rule your readers are welcome to it.

I think you will not find any rule that will take the place of experience. If we could make some rule by which we could get over the unreasonable demands and objections of whimsical women, and men as well, it would be a great benefit to the trade; but I fear this problem will be far more difficult to solve than the first one.



Heating Radiators from Furnace.

Heating Radiators from Furnace.

From C. L., *Baltimore.*—Will the system shown by the sketch give a good circulation of hot water from a furnace containing a boiler 12 x 24 inches with 1 inch supply? I shall be glad to receive any suggestions.

Note.—Our correspondent asks for assistance, and any suggestions from our readers will be welcome. In our opinion the system shown by the solid lines would not prove satisfactory. A better plan would be to run a 1½ inch pipe from the boiler A directly to B, as shown by the dotted lines, taking a 1 inch branch over to the radiator C and returning from the radiator to the boiler, taking out the pipes D, and the horizontal pipe from E to K. From B take a 1¼ inch branch to G, taking a 1 inch connection to the radiator H, and reducing the pipe to 1 inch and continuing to the radiator I. From the radiator H bring a 1 inch return to L, where a 1-inch connection should be made to radiator I, and the return increased to 1¼ inches and taken over to N, where the return should increase to 1½ inches and return to the furnace boiler A. A 1-inch pipe should run from N up to the expansion tank. An air valve should be placed at B, which should be made the highest point of the system. The pipe from M to L should be taken out.

Location of Expansion Tank.

From Rex, *Rochester, N. Y.*—In reply to the inquiry of "M. K." in *The Metal Worker*, March 31, the expansion tank should in all cases be placed on the highest line that the radiators are placed on, and connected both to the return and flow pipes, so that there will be a circulation through the expansion tank at all times. By doing this it will avoid any snapping and cracking in the heating pipes and also prevent the emptying of the boiler, if connected to same, through careless firing. By connecting the expansion tank as above stated, the tank can be placed in a colder place, such as attics, and a large vent pipe be run to some suitable point. So connected it is not very apt to freeze up and burst the boiler, as the writer has seen in a number of cases with the single connection.

T. C. Joy & Co., Titusville, Pa., manufacturers of the Joy steam and hot water heaters and radiators, recently made a slight reduction in wages, which was accepted by all their employees, with the exception of the moulders. The firm

do not anticipate any serious trouble and expect to be running with a full complement of men within a week or ten days.

HEATING NOTES.

Secretary Geo. H. Reynolds informs us that the headquarters of the Master Steam and Hot Water Fitters' Association of the United States will be transferred to the Broadway Central Hotel, New York City, May 1, and that all communications should be sent to that address after that date. This is the hotel that has been selected for holding the national convention June 19 to 21, and Secretary Reynolds will be found there up to that time.

Wm. M. Barber, heating engineer of the Smith & Anthony Company, Boston, Mass., made a visit to the New York house at 54 Beekman street, recently. Mr. Barber drew the plans for the Model School that were sent to the World's Fair by Chief Wade of the Massachusetts State Board of Inspectors.

Geo. P. Jacobs & Company, Brooklyn, N. Y., who make a specialty of supplies for steam and gas fitters and plumbers, are sending out a very convenient desk blotting pad. Cutting and threading pipe to specifications up to 10 inches in diameter occupies one department of their business and heating by either exhaust or live steam another.

The Penn Engineering Company, 312 Cherry street, Philadelphia, are putting on the market a ball joint pipe hanger which they claim will swing in any direction that the pipe expands and is easily adjusted.

The A. A. Griffing Iron Company, Frank Somers agent, will remove their Chicago office from 88 Lake street to 34 Dearborn street.

The Ringen Stove Company, St. Louis, have just completed what is considered one of the largest hot water heating contracts in the West, at the St. Joseph Orphan Asylum, St. Louis, Mo. There are about 18,000 feet of radiation in the building connected with a battery of two 5 x 18 foot boilers which contain each 72 lap welded boiler tubes 4 inches in diameter and 18 feet long. It was deemed advisable to place the boiler at a distance from the building for safety sake, and therefore a large tunnel had to be built purposely for the accommodation of the flow and return pipes for this heating construction. The boiler houses are 120 feet west of the asylum. In the tunnel are laid two 15-inch hot water flow and return mains, through which all water passes.

A. A. Griffing Iron Company, 15 Dey street, New York, have been made the Eastern agents for the Powers regulators, made by the Powers Duplex Regulator Company of Chicago. They have just closed a contract for their introduction in the schools of Long Island City, where they will be used for regulating the dampers in the air ducts as well as for controlling the fire. One of their new things displayed in their window is the Princess radiator, which is of the flue type, handsomely decorated.

The Barron Steam Heating Company have a fine office in the Cable Building, at Broadway and Houston street, New York, where they have just moved.

Pursuant on the death of Arad T. Foster, president of the Haydenville Mfg. Company, 73 Beckman street, New York, a meeting of the directors was held on April 5 to elect new officers. H. H. Beals, treasurer and secretary of the company, was elected president and general manager, retaining also his office as treasurer. Cuyler K. Sanborn, lately vice-president, was elected vice president and secretary. No changes will be made in the policy of the firm, which will continue to be carried out on the lines laid down by their late president.

T. C. Joy & Co., manufacturers of the Joy steam and hot water heaters and radiators, have moved their Chicago office to 82 Lake street.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

The plumbing contract, amounting to $4496, for the new post office at Lowell, Mass., is reported to have been let to the Dalton Company of Chicago.

A. V. Fetter, La Crosse, Wis., has been awarded the contracts for plumbing the new opera house at Stevens Point and also large buildings at Medford and Marshfield.

The James Steam Heating Company, 109 South Sixth street, Brooklyn, are engaged in remodeling the steam heating plant in the carriage factory of R. M. Stivers & Co., New York.

Sealed proposals will be received at the office of the Supervising Architect, Washington, D. C., until May 1 for the interior finish and plumbing of the United States Court House and Post Office building at Sioux Falls, S. Dak. Drawings and specifications may be had from the Supervising Architect, Washington, or from the superintendent at Sioux Falls.

The Smith & Anthony Company, Boston, Mass., are installing the heating plant in the High School building at Arlington, Mass. It is on the blower system with fan, two water tube boilers and the equivalent of 6000 feet of radiation.

Bids will be received by the Board of Education of Cincinnati, Ohio, up to April 16, for the heating and ventilating and a system of flush closets for an eight-room school building.

E. C. Worrell, Moorestown, N. J., will install a steam heating plant and do the plumbing work in the new residence of Samuel L. Allen, at Stanwick.

The contract for plumbing the Wachusett House, at Princeton, Mass., has been awarded to Wm. F. Tucker of Worcester.

The Theo. Jacobs Company, 72-74 Market street, Chicago, have contracted to furnish new boilers and heaters for the building occupied by the Columbus clothing store, State and Monroe streets.

E. Baggot, 169-171 Adams street, Chicago, has taken the contract for the plumbing and sewerage in the Garfield Building, Euclid avenue and Bond street, Cleveland, Ohio.

The J. L. Mott Iron Works, 311-313 Wabash avenue, Chicago, have received orders for two Sunray hot water heaters from Los Angeles, Cal.

Cook & Chick, 253-255 Kinzie street, Chicago, are to install steam heating plants in the flat building of Mrs. M. A. Roth, Jackson Boulevard, near Troy street, and in the flat building of George Bloom, Lawndale avenue.

Ring & Reardon, 3841 Finney avenue, St. Louis, have installed a number of Sunray hot water heaters and received orders for six more.

J. F. Connell, 687 West Indiana street, Chicago, has contracts for the plumbing and gas fitting in the residence of A. B. Campbell, 378 Hoyne avenue; flat building of J. B. Nash, 648 West Erie street, and residence of B. Byan, 840 West Chicago avenue.

The contract for heating and ventilating the new and old prison buildings and warden's residence at Norristown, Pa., has been awarded to the Penn Engineering Company, 312 Cherry street, Philadelphia. The bids were opened in the presence of the bidders and ranged from $4283 to $6031. The amount of the Penn Company's bid was $5210. Edwin F. Bertolette of Norristown, is the architect, and the bids were made upon specifications prepared by him.

J. Sidney Villere & Co. have designed for Miss Etta R Gregory a three-story apartment building to be erected at 16 and 18 St. James place, Chicago, at a cost of $18,000, which will be heated from a hot water plant.

Babb, Witham & Kelley, the plumbers and steam heaters, are installing a steam heating plant in St. Mary's Parochial School, at Bangor, Maine.

Dilworth Carter is building a $6000 residence at Astoria, Ill., which is to be heated by steam or hot water, for which estimates are desired.

D. H. Kelly has secured the contract for the plumbing and steam fitting for the new factory of the Williams Typewriter Company, at Derby, Conn.

Bids will be received until April 16 for the plumbing, gas fitting, heating and ventilating of a High School building to be erected at Lincoln, Neb.

The S. Wilks Mfg. Company, 113 Clinton street, Chicago, have shipped four of their heaters to the Rider Heating Company, Helena, Mont.

Foster & Glidden, general agents for the Farquhar Heating Company, 58 Dearborn street, Chicago, report the following contracts: Hot water heating in the residence of D. N. Hanson, Forty-eighth street and Ellis avenue, and residence of A. B. Smillie, Norwood Park, Ill., steam heating in Park Home Hotel, Blue Island, Ill., and combination heating in residence of F. P. Bagley, Hinsdale, Ill.

A petition signed by 830 captains of British ships navigating the North Atlantic, commanding a gross tonnage of nearly 2,000,000, and representing crews of about 30,000 men and capital of $150,000,000, has been forwarded to the British Government, praying them to make prompt co-operation with the United States Government in destroying ocean derelicts, which constitute a great danger to life and property on the Atlantic.

The Russo-German commercial treaty, recently arranged after much opposition, went into operation on the 20th inst. It is to remain in force for 10 years.

PLUMBING and GAS FITTING.

Pratt Institute Graduates in Plumbing.

On the evening of March 23 a committee of the Journeymen Plumbers' Association of Brooklyn visited the trade school of the Pratt Institute, and held an examination of the plumbing class, with the view of awarding certificates to those students who had completed the prescribed course of study. The examination included an inspection of the work of the candidates and questions by the Examining Committee, which covered a thorough knowledge of methods and work, together with the sanitary and scientific conditions underlying the subject.

Certificates were awarded to six students—namely:

J. S. Wright,
L. Calahan,
J. J. Heilman,
J. Munk,
A. L. Maxwell,
C. B. Kineo,

all of Brooklyn. The committee were accompanied by three master plumbers, who expressed themselves warmly in regard to the progress and efficiency of the class.

These certificates were for the first time, under the new arrangement, granted by the Board of Directors of the Journeymen Plumbers and Steam and Gas Fitters' Helpers of L. U. No. 1. They were countersigned by the trustees of the institute. The institute no longer grants certificates to the evening classes.

Trouble Among Chicago Plumbers.

The Chicago plumbers have decided to strike unless their employers agree to pay the same wages during 1894 that were paid last year. The journeymen plumbers have submitted to the employers individually an agreement, of which the following is a copy:

Agreement entered into between the undersigned employing plumbers and the Chicago Journeymen Plumbers' Protective and Benevolent Association:

SECTION 1. That the hours of labor shall be from 8 a.m. until 5 p.m., with one hour for dinner, and on Saturday from 8 a.m. to 4 p.m., with one hour for dinner, excepting the Saturdays from June 15 to September 15, when the hours of labor shall be from 8 a.m to 12 m.

SEC. 2. That wages shall be $3.75 per day, excepting the Saturdays between June 15 and September 15, for which they shall be $2.25.

SEC. 3. That wages are due and payable when work ceases on Saturdays.

SEC. 4. All Sunday, New Year's, Christmas, Fourth of July, Thanksgiving and overtime work shall be paid for at the rate of double time.

SEC. 5. That members working outside the city of Chicago shall be subject to all the conditions of this agreement, and in addition thereto shall have their board and railroad tickets furnished; traveling time paid at the rate of regular time; when traveling at night sleeper to be furnished where the distance is more than 100 miles; no charge for time traveling at night; Sunday traveling to be paid at single time.

SEC. 6. That sections 1, 3, 4 and 11 of this agreement shall also govern the junior plumbers.

SEC. 7. That all men shall be held responsible for incompetent work when it is due to their negligence and other causes directly traceable to their carelessness and incompetency.

SEC. 8. That whenever a question shall arise between the employing plumber and the employee in regard to inferior work done by said employee, and said question cannot be settled by said parties, then an Arbitration Committee shall be appointed consisting of two plumbers, one to be selected by the employing plumber and the other by the Journeymen Plumbers' Protective and Benevolent Association, and in case said committee of two cannot agree, then said committee shall select a third party, and the decision of the majority of said committee of three shall be final and binding upon both parties.

SEC. 9. That no more than one helper shall be allowed for every three journeymen plumbers working in a shop.

SEC. 10. When more than one man is required on a job it must be under the supervision of a journeymen plumber.

SEC. 11. A sympathetic strike, when ordered by the Building Trades' Council, will not be a violation of this agreement.

SEC. 12. That this agreement shall continue for the space of two years, beginning on the first day of April, 1894, and ending on the first day of April, 1896.

SEC. 13. That in case the parties to these presents shall desire to enter into a further agreement at the expiration of this agreement, then said agreement shall be made by and between said parties at least three months previous to the expiration of the present agreement.

In witness whereof the parties to these presents have hereunto set their hands and seals.

....Name.

.. .. Address.

CHICAGO JOURNEYMEN PLUMBERS' PROTECTIVE AND BENEVOLENT ASSOCIATION.

By .....

The agreement submitted by the Master Plumbers' Association to the union contains the following clauses to which strong objections are made by the men:

That wages shall be $3 per day excepting the Saturdays between July 15 and September 15, for which they shall be $1.50.

That the members of the Chicago Journeymen Plumbers' Association will be responsible for their work, for their incompetency, and that said association shall be responsible for said incompetency.

That this agreement shall continue until December 31, 1895.

That journeymen plumbers furnish their own furnaces.

A large and enthusiastic meeting was held by the Chicago master plumbers, at their hall, 197 Madison street, on Monday afternoon, April 2. The unanimous opinion of those present was that some of the demands made by the Journeymen's Protective and Benevolent Association were unjust.

A large number of the master plumbers who were interviewed criticised the proposed journeymen's agreement as follows:

Sec. 2. The reason the full amount of wages was not conceded was that many investors, having plans prepared, and comparing them with like plans executed during the World's Fair season, discovered that there was not sufficient difference in the estimates offered as compared with the general decline in the price of material, and have not, therefore, entered into the construction of the buildings intended.

Sec. 4. Regarding this section, only time and a half should be paid for overtime between 5 p.m. and 12 m.

Sec. 5. Objected to.

Sec. 8. We do not know what value the agreement would be to us if section 8 was adopted.

Sec. 9. The helper question should be regulated by the Master Plumbers' Association.

Sec. 10. Superintendents of work should always be at the discretion of the employer.

The journeymen plumbers claim that they have already secured a number of signatures of employers to their proposed agreement, but the Master Plumbers' Association assert that those who have signed are only master plumbers running small shops and employing very few men.

TRAPS AND VENTS.

THE BOARD OF HEALTH of Norfolk, Va., have recommended an ordinance to the City Council for adoption that was prepared by a joint committee of master and journeymen plumbers.

THE FOLDING BATHTUB COMPANY, Marshall, Mich., send out colored circulars calling attention to the folding bathtubs of their manufacture. In addition to these specialties the firm also make stationary bathtubs, bath heaters, sanitary bath chairs, clothes hampers, combination commodes, &c.

SAMUEL DAVIDSON of the Steel Clad Bath Mfg. Company, New York, is on a trip through the South explaining that the Steel Clad bath has all the advantages of the wood copper lined bath and all of the advantages also of an exposed plumbing fixture.

The Metal Worker is indebted to Plumbing Inspector Wm. Lunn of Memphis, Tenn., for a copy of the plumbing ordinance recently passed by that city. In a letter inclosing the ordinance he says: "Our sewer system is of the G. E. Waring design, and in many places very near the surface. A large amount of our laterals from the 20-inch main are 6-inch pipe with 4 inch house connections, and each lateral has a great many house connections. The system gives general satisfaction." With a loyal pride he adds, "I will also state that our plumbing will compare favorably with that of any other city".

MARK R. DAYKIN of the plumbing firm of Daykin Bros., Cleveland, Ohio, is a candidate for the School Council of his city at the spring election.

THE BOARD OF HEALTH of Sacramento, Cal., have elected G. W. Horr sanitary and building inspector and Victor J. Talley plumbing inspector.

THROUGH AN ERROR a plumbing ordinance of New Haven, Conn., omits the word "iron" after the words "extra heavy," relating to drain pipes. As a result a spirited contest has waged between a sewer contractor and the

mayor, which will end in the ordinance being amended.

Murray & Maher, New London, Conn., have moved their plumbing and tin shop to 15 Main street.

Dedham, Mass., has under consideration a system of plumbing regulations.

Jacksonville, Fla, has passed an ordinance of 15 sections remodeling the plumbing ordinance of 1889. The plumbers will now have to pass an examination and do their work on the approved modern plan.

The Master Plumbers' Association of Newark, N. J., have made application for membership in the National Association of Master Plumbers, so we are informed by Secretary Don.

The New York Trade School will continue the day class in plumbing, beginning April 9, until April 28, for the benefit of such pupils as desire more practice.

The Court of Special Sessions of New York City last Monday inflicted a fine of $10 on a First avenue plumber who was doing work in violation of the law requiring a certificate of competency and a license. Several other cases are before the court for trial.

Manchester, N. H., has a new set of plumbing regulations of 24 sections.

Widdos & Shaneberger have opened a plumbing establishment at 459 Northampton street, Easton, Pa.

Macon, Ga, is to have a system of sewers, amounting to a length of 42 miles. Gabourg & Noble, Anniston, Ala., have the contract at $100,000.

J. W. Chamberlain & Co, plumbers, have been incorporated, at Bangor, Maine. Joseph W. Chamberlain is president of the new concern and Joseph E. Chamberlain treasurer.

The Detroit Master Plumbers' Association held a reception and ball at Clawson's Hall, 96 Miami avenue, Detroit, on the evening of the 4th inst.

Grant Crittenden, Pekin, Ill., has taken a partnership with Henry Hurkett in his plumbing business.

Arthur Shea, Rockland, Maine, has been making extensive improvements in his plumbing shop in the Glover & Ames Building in that city, where he has been located for the past 12 years.

John C. C. Bohlman & Co. is a new plumbing concern that has gone into business at Pittsfield, Mass.

Smith & Webster, 193 Lake street, Chicago, have moved their plumbers' supply factory to 15 to 21 North Clinton street. The show-room will remain at 193 Lake street until May 1, when a more central location will be secured.

George Fish is arranging to open a plumbing establishment in the Schlosser Building on Ferry street, Albany, Ore.

A. G. Hale and L. W. Thurston, both lately with L. E. Smith & Co., have formed a partnership and will conduct a general plumbing business under the firm name of J. P. Hale & Co. at the store 12 Short street, Gloucester, Mass., formerly occupied by Richard Tufts. They will carry a stock of stoves, furnaces and plumbers' materials, and will pay special attention to tin roofing, pump and vessel work in addition to sanitary plumbing, ventilation and house drainage.

FLASHINGS.

A company, under the style of the Baker Red Slate Company of Troy, N. Y., have been incorporated by Troy capitalists to quarry slate at North Granville, N. Y., with a capital of $100,000.

Most of the slate workers in the Bangor and Pen Argyl district, Pa., struck this week against a reduction of wages recently put into effect. The men are now paid from 85 cents to $1.25 a square, but demand a return to the old scale. It is thought that there will be a general cessation of work in the quarries until the question is settled. The slate industry is just reviving after several months' slackness, and the quarries were running at their fullest capacity.

As an evidence of reviving activity in the building industry the large shipments of roofing slate made by the Slatington-Bangor Syndicate in the month of March are significant. They were much above those of January and February and beat all previous March records. The shipments were in 90 carloads, comprising 4341 squares, and were sent all over the United States east of the Rocky Mountains. The syndicate is said to have orders booked for the season for 25,000 squares, and they regard the outlook for the slate trade in the present year as being remarkably good.

Marlin & Co., Incorporated, Allegheny, Pa., manufacturers of eave troughs and water conductors, have recently added considerable machinery to their equipment and are now prepared to furnish a full line of round and corrugated water conductors in 10-foot lengths. Included in the new machinery added by this firm is a 10-foot power squaring shear, also a forming machine for making eave troughs up to 10 feet in length. For some time past this firm have been working on large orders for galvanized iron cans, to be used for freezing artificial ice. Orders for these cans have been received from artificial ice makers in Philadelphia, Pa., Louisville, Ky., Massilon, Ohio, and other points. The business of Marlin & Co., Incorporated, was established in the present location in Allegheny, Pa., a few years ago under the name of Armor, Marlin & Co., and later changed to Marlin & Co., and finally to Marlin & Co., Incorporated, and has grown very rapidly. Their trade for last year was considerably larger than for any year in their history, notwithstanding the general depression in business. At this time the firm are fully occupied in turning out their various products, and are giving employment to a large force of men.

The iron and steel roofers of Ohio have apparently found bottom on prices and are now getting down to business. Orders are reported more plentiful and the general appearances of activity at the various factories are more satisfactory. Nearly all the roofing and corrugating concerns of Ohio have now become extensive users of galvanized sheets and report increased demand for that class of goods.

The American Roofing Company, St. Louis and Cincinnati, report an improved trade, which has enabled them to equal their March business of last year. The outlook for the present month is excellent, and unless something unforeseen occurs they expect to also equal their April record of last year. They report a good demand for gutters, conductor pipes, elbows, &c. They have just issued a new catalogue relating to these goods, which is now being mailed to the trade.

OBITUARY.

WILSON C. BERGER.

Wilson C. Berger, superintendent of the Berger Mfg. Company, Canton, Ohio, died April 2 after an illness of three weeks. Mr. Berger was born in Millersburg, Pa., 43 years ago. While he was a boy, but 19 years of age, he went to Canton and has resided there ever since, always taking an active part in business and charitable enterprises. In 1872 Mr. Berger married Miss Mary Myers, who with a daughter and two sons survive him. Mr. Berger was a solid and experienced business man and very popular among his employees and friends. His name has become prominent in manufacturing industries, and the business with which he was connected has prospered under his skillful and conscientious management.

JOHN WILKESON.

The death is announced, on April 4, of John Wilkeson, one of the oldest and best known citizens of Buffalo, at the age of 88. Mr. Wilkeson, who was born at Poland, Ohio, was in his earlier days a prolific inventor, and held many patents on stoves and heaters. With his father and brothers he was largely engaged in the iron business in Western New York and Ohio. Later he became interested in the timber and elevating business. He saw active service during the war, in which one of his sons was killed.

ARAD T. FOSTER.

We regret to announce the sudden death, at his home in Brooklyn, on March 30, of Arad T. Foster, president of the Haydenville Mfg. Company and vice-president of the Peck Bros. Mfg. Company of this city. We will give a fuller notice of Mr. Foster in a later issue.

Milk Can for Mule Back.

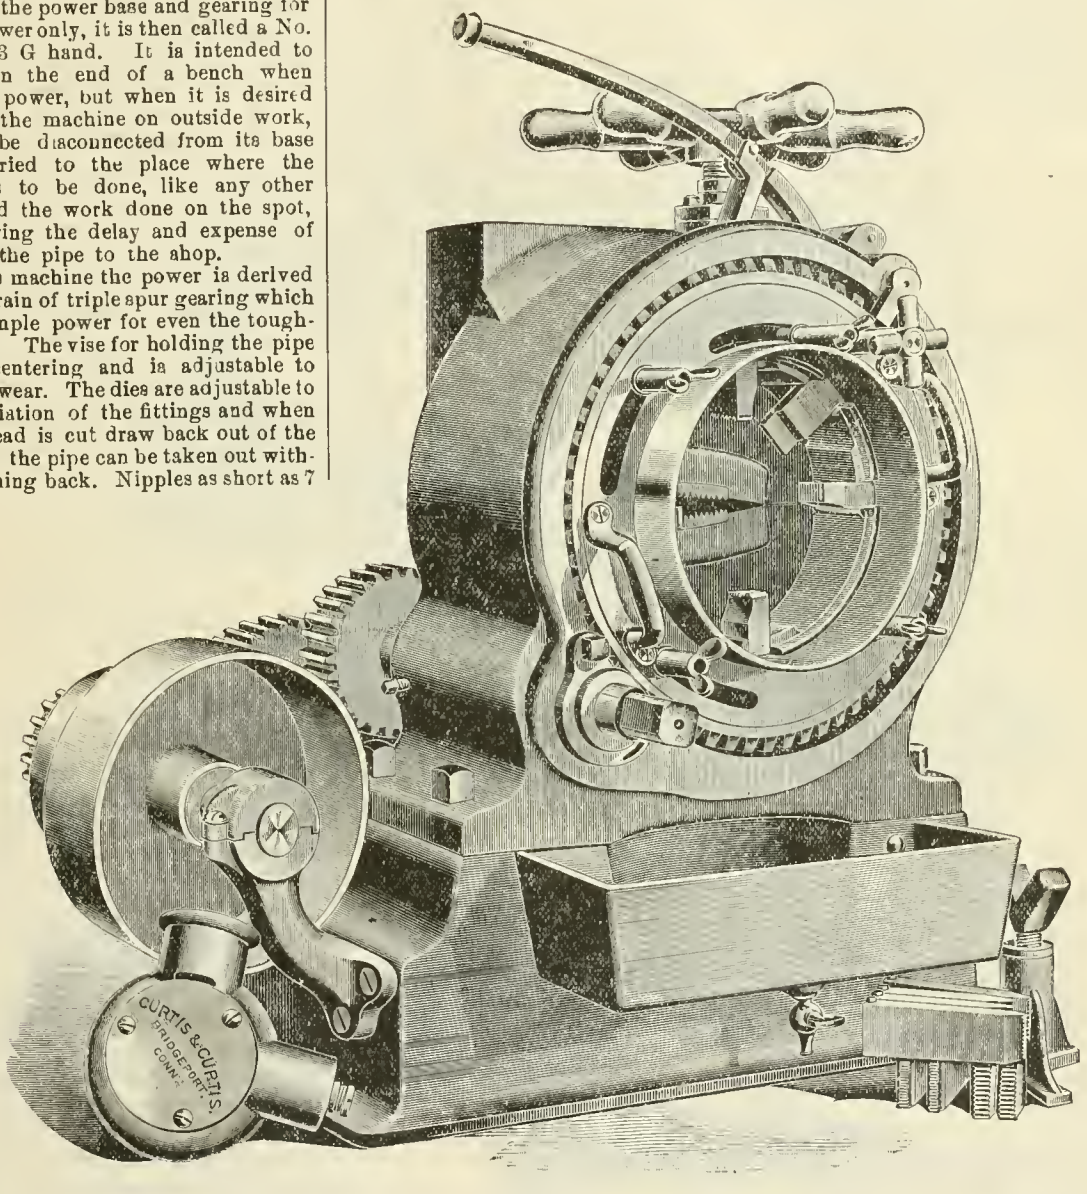
Iron Clad Mfg. Company, 22-24 Cliff street, New York, are manufacturing a novel milk can for fastening on each side of a mule for transportation in mountainous sections. These are sent principally to South American countries, where the milk dealer serves his customers by this method instead of using a horse and wagon, as with us. The can is 21 inches high, 19 inches long and 9 inches through. The top and bottom are round, while the center on both sides is slightly concave, to fit the mule's sides. They are made in three capacities, 5, 8 and 10 gallons. The material is No. 20 gauge sheet steel, tinned. In the center of the top is a 5-inch round opening, so made as to be absolutely tight, the cover being fitted with a lever and rubber gasket, the whole contrivance projecting about 2 inches above the top of the can. The sides extend ¾ inch beyond both ends. On the top are two milk can handles, while the bottom has one.

Indications in the Lake Superior region point to the earliest opening of navigation on record. Everything of this character helps in the revival of business and in the employment of men who have long been idle.

New Form of Forbes Die Stock.

Curtis & Curtis of Bridgeport, Conn., have just brought out a new development of the Forbes patent die stock, which is here illustrated. It is operated by hand or power and is designed to cut off and thread, right hand, all sizes of wrought iron pipe from 1 to 6 inches inclusive. When this same machine is supplied with both right and left hand dies, it is then called a No. 3 G power machine, and when made without the power base and gearing for hand power only, it is then called a No. 3 F or 3 G hand. It is intended to stand on the end of a bench when used by power, but when it is desired to use the machine on outside work, it can be disconnected from its base and carried to the place where the work is to be done, like any other tool, and the work done on the spot, thus saving the delay and expense of carting the pipe to the shop.

In this machine the power is derived from a train of triple spur gearing which gives ample power for even the toughest pipe. The vise for holding the pipe is self centering and is adjustable to take up wear. The dies are adjustable to any variation of the fittings and when the thread is cut draw back out of the way and the pipe can be taken out without running back. Nipples as short as 7 inches can be made without a nipple holder, and with the aid of the Curtis nipple holder, manufactured by this firm, short or close nipples can be made.



New Form of Forbes Die Stock.

Argentina's condition is regarded as very promising. Official reports show that the country during 1893 maintained a steady recovery from the depression of previous years. Immigrants numbered 110,226, while the departures were only 64,100, leaving a balance of 46,126 in favor of the republic.

Yet another ship canal is about to be undertaken on this continent. Last week the Ontario Legislature granted a franchise incorporating the Huron-tario Ship Canal Company and empowered it to have one terminal point on Lake Ontario, near Toronto, and another on Georgian Bay, near Collingwood. This canal will, it is claimed, shorten the route from the West to Liverpool by 800 miles. The capital stock of the company is placed at $65,000,000, and a number of American capitalists are said to be interested in the scheme.

According to the *Labor Gazette* of London, labor disputes in England last year involved 602,668 persons. Of these strikers 390,844 were successful and 134,864 were partially successful, while 68,934 were unsuccessful, and the results were not known in the cases of 8026. The figures for 1893 are of unusual interest, since they embrace the results of the Lancashire cotton strike early in the year and the great coal strike in the summer and fall. The latter dispute is included among the "successful" ones, which accounts for the large figures under that heading.

Among the companies recently incorporated according to the laws of the State of New York is the New York & Chicago Ferris Wheel Company of New York. With a capital of $600,000 the concern will manufacture and exhibit wheels of the Ferris type, constructed for purposes of observation and amusement. The directors are named as follows: Geo. W. G. Ferris of Pittsburgh, Andrew Onderdonk of Chicago, and F. L Marshall, Anson Maltby and Wm. G. Russey of New York City.

M. Bartissol's scheme for the carrying out of the Panama Canal project is said to include a plan for the cutting of a stone tunnel some six miles long through the high level of the canal. Into this the Chagres River is to be turned, and through sluices it is to be discharged into the excavated earth, the force of the stream being counted on to carry the earth off to the Pacific Ocean. Owing to the liability of the river to swell dangerously during freshets, the plan is, however, regarded by some engineers as impracticable.

Experts assert that the passage of the new ship canal across the Isthmus of Corinth is not without possible danger to steam vessels. At certain points, it is said, the danger of a landslip, notwithstanding all precautions, is not excluded. It is believed that the larger portion of the traffic through the canal will be composed of sailing vessels.

J. Stub has opened a tin shop at Brownsfield, Maine.

THE TIN SHOP.

Pattern for Four-Piece Elbow.

From L. A., *New York.*—I would like to have a method published in *The Metal Worker* for describing the pattern of a four piece elbow.

Answer.—In Fig. 1, let *e f g h* represent a cylinder cut by planes oblique to its axis, as shown by *o o'*, *p p'* and *q q'*. An inspection of the figure will show that the angle *e o o'* is similar to the other like angles, as *o o' p'*, *p' p q* and *q q' g*. If these sections A, B, C, D were placed together as shown by A*a* B*a* C*a* D*a* in Fig. 2, a four-piece elbow would be the result. In Fig. 3 the elevation of a four-piece elbow, similar to that in Fig. 2, is shown in connection with the profile and half pattern. To obtain the elevation, draw the square J K L M, and from J as center strike the arc M P K. Also draw J L. Divide the eighth of a circle M P into one less number of parts than there are to be pieces in the elbow, and as in the present instance there are to be four, M P is to be divided into three equal parts, as indicated by the small figures in M P. From the first division, as O, draw O J. Make K Q equal to M O, and draw Q J. From O drop the perpendicular O G, and from the point N set off the diameter of elbow, as shown by N *n*. Through point *n* draw E *o* parallel with G O, and also draw E G parallel with J M. With *x* as center strike the profile E F G H, and divide E F G into any convenient number of equal parts. From the points thus obtained erect perpendiculars, cutting the miter line O J, as shown. Connect the points O P, P Q, and draw Q R parallel with L K. Make J *p* and J *q* equal to J *o*, and draw *o p*, *p q*. Also draw *q r* parallel with Q R. Then R Q P O N *n o p q r* is the elevation of a four-piece elbow.

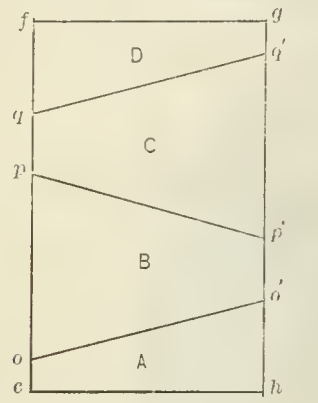


Fig. 1.—Elevation of Cylinder from which Sections are Obtained.

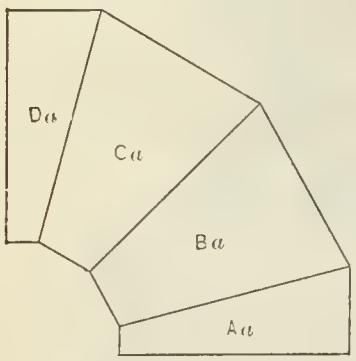

Fig. 2.—Sections Placed Together so as to Form an Elbow.

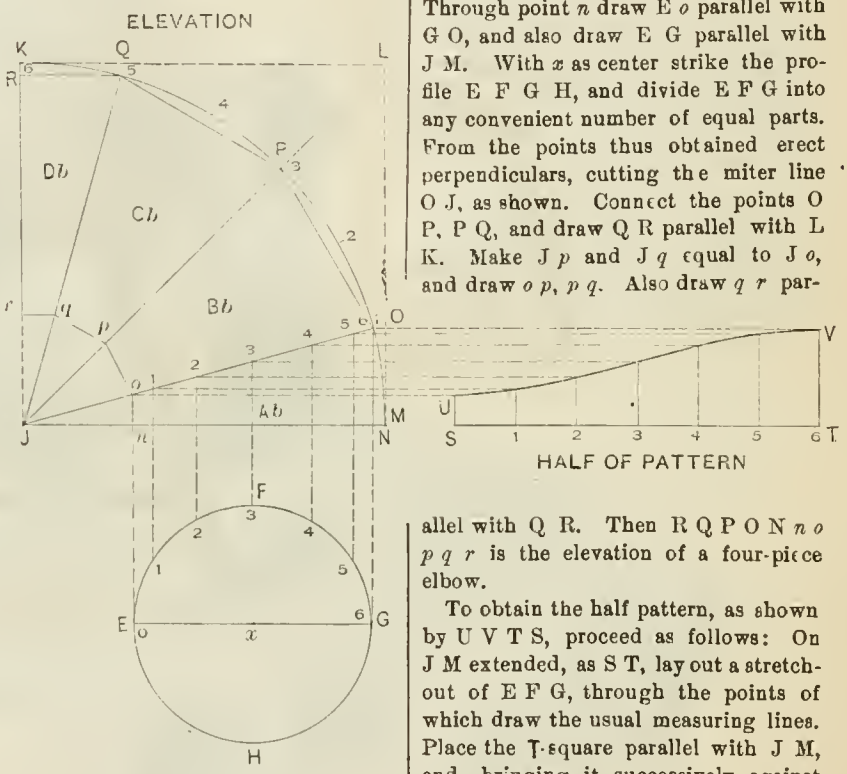

Fig. 3.—Method of Obtaining the Half Pattern.

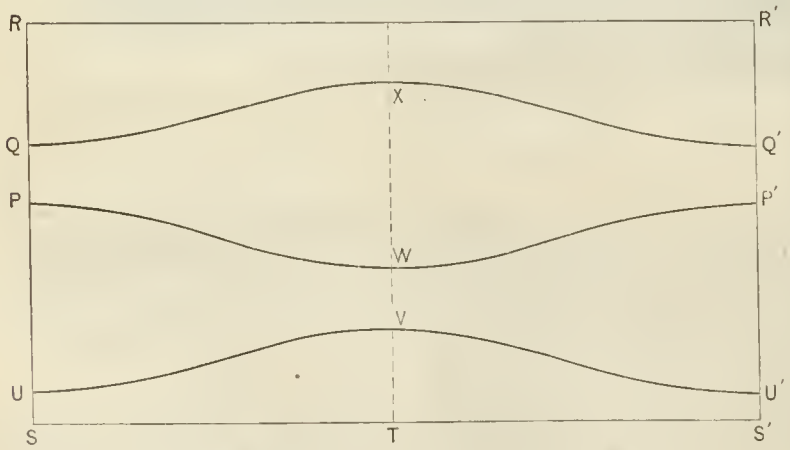

Fig. 4.—Half Pattern Used for Obtaining Pattern of Whole Elbow.

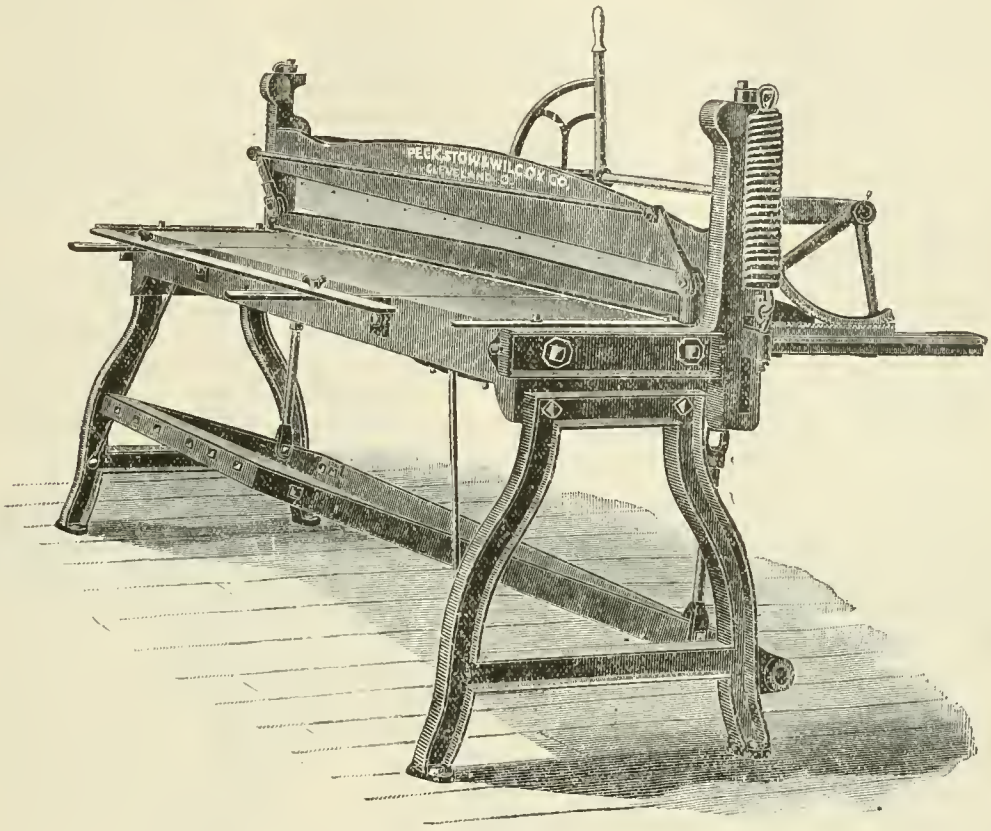
PATTERN FOR FOUR-PIECE ELBOW.

To obtain the half pattern, as shown by U V T S, proceed as follows: On J M extended, as S T, lay out a stretchout of E F G, through the points of which draw the usual measuring lines. Place the T-square parallel with J M, and, bringing it successively against the points in the miter line J O, cut the corresponding measuring lines. A line traced through the points thus obtained, as shown by U V T S, will form the half pattern of part of elbow shown in elevation by O N *n o*, or in profile by E F G. It will be observed that only part of the elevation has been used for obtaining the half pattern, which was derived from the miter line J O in connection with the profile E F G H. In practice it is only necessary to draw the half profile E F G, and above, and in line with same, the right angle J M L, making M J and M L the same length. Connect J L, and with J as center strike the arc M P, which is the eighth of a circle. Divide M P into one less number of parts than there are to be pieces in the elbow, and from the first of these divisions, as O, draw the miter line J O. The pattern is then to be obtained as previously described. The entire pattern of elbow, as shown in Fig. 4 by R R' S S', can be obtained by the use of the half pattern U V T S, as follows: On the line S S' lay the half pattern and mark about it as shown by U V T S. Re-

verse the pattern and mark T V U′ S′. From S and S′ erect the perpendiculars S R and S′ R′. Make U P and U′ P′ of pattern equal to O P of elevation, and also make V W of pattern equal to *o p* of elevation. By using the pattern as previously described, draw P W and W P′. Q X Q′ can be drawn in a similar manner. Make S R and S′ R′ equal and draw R R′. The usual allowances for joining to be made on S R and S′ R′.

Cornice Makers' Squaring Shear.

Peck, Stow & Wilcox Company, Cleveland, Ohio, and 27 Chambers street, New York, are introducing an improved cornice makers' squaring shear, as here shown. This shear is brought out principally for the use of cornice makers and is supplementary to an extensive line of squaring shears made by this concern. It has a hold down attachment and gauges for squaring and cutting at angles, with a lever on graduated arc for working the back gauge with gear and rack from the front of the shear. The arc has a scale up to 27 inches, showing fractions of an inch, and by means of this device the gauge can be set at any point instantly, without leaving the front of the machine. The shear is made in but one size, 97 inches, and is warranted to cut No. 22 iron.

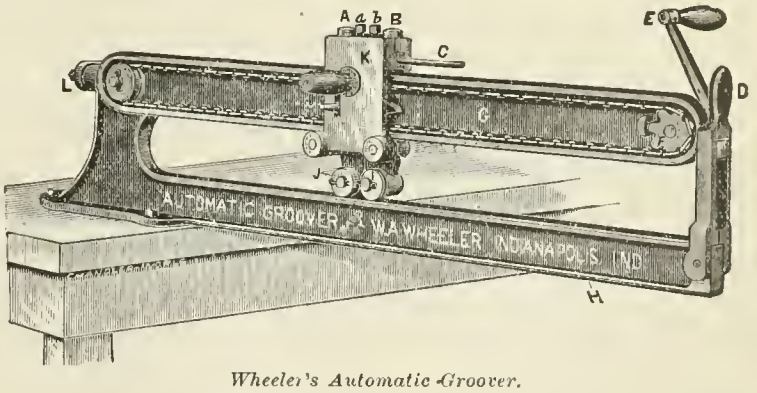


Improved Squaring Shear for Cornice Makers.

Official returns recently published show that the output of coal last year from the English Midland districts was affected by the coal strike to the extent of nearly 17,000,000 tons, compared with the preceding year. The falling off was comparatively as great in the other mining districts of Great Britain.

Wheeler's Automatic Groover.

We show in the accompanying illustration an automatic groover recently brought out by W. A. Wheeler, Indianapolis Elbow Company, Fort Wayne avenue and St. Clair street, Indianapolis, Ind. It is described as quite new in design, it being operated from the outer end, as indicated in the illustration. The operator can thus handle the work and run the machine without stepping out of his tracks, thereby saving much time. The carriage or sliding head, containing the grooving and seaming down rolls I and J, is brought forward over the work by means of a new device, consisting of a chain and sprocket wheel attached to the crank. A latch, M, pivoted within the sliding head, makes the connection with the chain and brings the head forward when the crank is turned. When the carriage has reached the end of its travel a projecting lug seen near the sprocket wheel strikes the beveled end of the latch, tilting it upward, thus freeing it from the chain and causing it to stop automatically. At the same time and just before the carriage comes to a stop, the pusher rod C strikes the top end of the clamp D, and throws it over simultaneously with the stopping of the carriage. The operator now takes hold of the handle on the side of the carriage with the left hand, and with one finger holding up the latch M, quickly shoots the carriage back to the starting point without moving the crank, thus releasing the work. The latch M is now ready to engage the chain again, which it does when the crank is turned. The automatic groover is designed to groove and roll down at one operation the seams on any kind of tin or sheet iron work, from the lightest tin to sheet iron as heavy as No. 24 gauge. It will groove pipe from 2¾ inches diameter and upward 30 inches long. Suitable rolls are furnished with each machine for the different kinds of work, and they can be quickly changed by simply removing a spring pin from the stud that carries them. The sprocket wheel, which drives the chain, is turned up true and the teeth milled out from the solid. Ample provision is made for adjustment and taking up of wear or lost motion.



Wheeler's Automatic Groover.

New York Trade School.

Thirteenth Annual Commencement.

Last Thursday evening an audience composed of 100 ladies, as many prominent tradesmen and over 500 scholars gathered in the auditorium of the New York Trade School, at Sixty seventh street and First avenue, which was tastefully decorated, to participate in the commencement ceremonies. At 8.30 p.m. President R. Fulton Cutting secured for the speakers a sympathetic audience by his genial welcome and promise that only inspiring speeches would be heard, as every speaker was either an officer or an ex-officer, and a natural leader. He then introduced John Byrns, ex-president of the National Association of Master Plumbers.

Address of John Byrns.

Mr. Byrns began by saying he had attended all of the commencements of the school, and grew prouder each year of the boy who gave up his nights or left his home to become a mechanic. Amid so many happy influences there was sorrow for the vacant chair of the founder of the institution, the late Col. Richard T. Auchmuty. He was present in spirit, however, and the world was better for his having lived. The work that he had started had now become a monument established to a memory that would compare with that other notable American, Peter Cooper. It had been so difficult at one time for the American boy to secure a chance to learn a trade that a great strike had been the result among the plumbers of New York, and he was sorry to see that again a movement was being made to interfere with apprentices.

"The old guard who surround me on the platform fought to a victory then, and are prepared to enter the fight for the boys again. Personally I am opposed to proscription against the American boy, and rather than submit to it I would go down to my Babylon home and raise non-union potatoes. Forty-three years ago I had no such chance as you have, who have had the best instructors in the world. In those days we could do as nice lead work as any of the samples you have shown, but we did not understand the vent, the syphon, and the science of the business, which you have been thoroughly taught. You are now going out to work, and there is plenty of room for you. If you want success, deserve it. I don't want to caution you about stealing lead and solder when I say be honest, but when you contract to give a man an hour's labor, 'render unto Cæsar the things that are Cæsar's.' We have raised plumbing from a mere trade to a profession, and in following it I want you to bring credit to it, to the Master Plumbers' Association of this city, which has done so much for you, to the school, which is an inestimable benefit contributed by a most worthy citizen, and to yourselves."

Presentation of Certificates.

President Cutting then stated that certificates of their proficiency would now be presented and introduced Wm. H. Oliver, who gave to the evening class ten certificates to house painters and 12 certificates to fresco painters and to the day class 13 certificates to house and sign painters.

The Allison Medal.

Every year the pupil who has shown the greatest ability in the various branches of painting is presented with a medal furnished by Wm. M. Allison and this year it was awarded to Nathan H. Larkin, who accepted it with a very graceful speech thanking Mr. Allison, Instructor McGowan and the awarding committee.

John H. McCullagh presented 36 certificates to evening scholars and 21 to day scholars in the carpentry class.

Mr. Cutting then introduced Stephen M. Wright, secretary of the General Society of Mechanics and Tradesmen.

Mr. Wright's Address.

In beginning he stated that he represented no organization of one branch of mechanics, but a society that had labored to uphold the whole mechanical interest of the nation. He stated that the founder of the institution had the aim of freeing the American boy from the opposition to his entrance to the trades, and his success enabled the scholars to reap a great benefit. "In your future enjoyment of the great privilege I caution you from ever interfering with others rising, but rather extend a helping hand to repay the favors you have received."

John Hughes presented 10 certificates to the plastering class, 3 to the stonecutting and 14 to the blacksmithing class.

Thomas J. Tuomey presented 40 certificates to the evening plumbing class, and Edward Murphy explained the amount of study in drawing, bookkeeping and lectures in addition to the manual training that was necessary to secure a trade school certificate, in presenting 114 certificates to the day class in plumbing.

The Trade School Yell

then shook the building, in surprise to all but the boys who gave:

"Zip! Boom! Rah! Hear us roar! Trade school boy of 94! Rah! Rah! Rah! Who are we! Plumbers!—As you all can see! Zip! Boom! Rah!"

Which was followed by a cheer for chief instructor of the plumbing class, John Delehanty, who is held in high esteem by all of the scholars.

President Cutting's Address.

Mr. Cutting stated that he was sorry that ex-Mayor Abram S. Hewitt of New York City was unavoidably absent, as it made it necessary for him to fill the place of a prominent speaker. Once, on being introduced to speak in the place of Chauncey M. Depew, as he arose half of the audience arose also and went out; but here he felt more sure of his audience. He then told how Colonel Auchmuty fought to preserve his country and at the close of the war began another patriotic fight in the interest of skilled labor. Taking as an example the Normans, who invaded England centuries ago and who built churches to establish morals for the country which now stands in the foremost ranks of the world, Colonel Auchmuty had established the trade school to build up skilled labor with a reputation for honesty and industry. "Having learned much here it is natural for you to think you can teach others a great deal, but in your teaching do not neglect to instill integrity into your life and the lives of your associates. Join the unions of organized labor and infuse into them the ideas of liberality and intelligence. They need you as a purifying influence and to teach them that the trade school is a boon to coming men. I now say good-by, commending to you the feeling of fellowship here engendered, and would have you remember that you represent the trade school and its interests. I may never see many of you again but, my interest will follow you always and everywhere. Should we meet again I shall be glad, and again I say good-by."

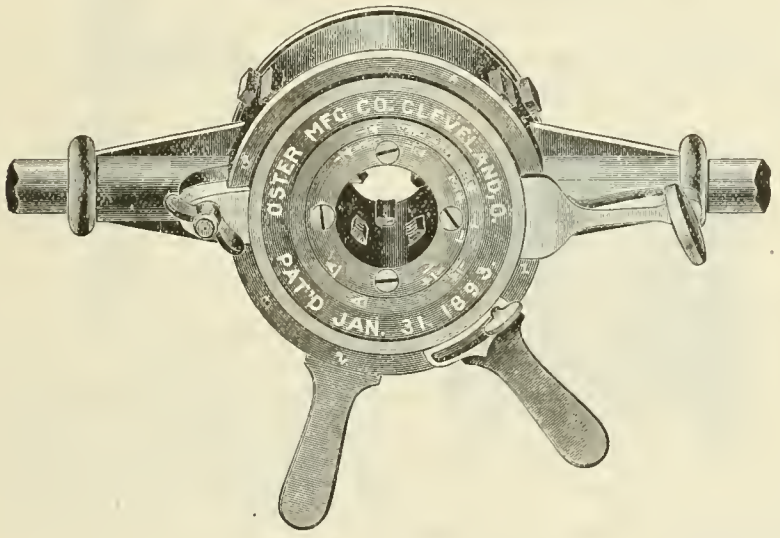
The Oster Adjustable Die Stock.

The cut shown herewith is of an adjustable die stock offered by the Oster Mfg. Company, Cleveland, Ohio. The tool is for hand use for threading pipe and bolts, one stock threading from four to six sizes. It is stated that the stock is made of a new process metal, many times stronger than steel in breaking quality, and that the dies are a special brand of fine steel, strong and durable,



The Oster Adjustable Die Stock.

and that they may be sharpened on a grindstone. It is explained that large pipe can be easily threaded by taking two cuts; that a cut off may be included if desired, combining two tools in one—threading and cutting off; that there is no waste of material, and that oil holes give an opportunity of oiling the dies while in use. The manufacturers claim that the stock is self centering, making a perfect thread every time; that in use no turning back over threads is necessary; that the stock is instantly adjustable and removable; that the adjustable positive stop enables the operator to thread any number of pieces of a given size without resetting, and that the device for holding the cams in position while threading is positive and warranted not to slip. The dies and guides are operated by a cam movement, having suitable handles to enable the operator to easily adjust them to any desired size. The tool is made in six sizes, for pipe from ⅛ to 4 inches. Stocks cutting from 1½ to 4 inches have four handles; other sizes have two handles.

The last Wisconsin Legislature enacted a law doing away with the three days' grace on promissory notes, the law to take effect April 5 of this year. There has been considerable doubt as to what effect the law would have on paper issued on or before April 5. Last week the bankers of Milwaukee issued the following: "By advice of counsel in whom we have full confidence, the banks of Milwaukee have concluded that the law abolishing the days of grace in Wisconsin will take effect and be in force April 6, 1894. We conclude that the act applies to negotiable paper issued on or after April 6, 1894, and not to paper executed prior to that date. We do not believe that the law can apply to negotiable paper in existence at the time it was passed, because it would impair the obligation of the contract; nor to negotiable paper executed prior to April 6, 1894, because it does not take effect until that date, and there are no words evincing any intent of the Legislature to make the act retroactive."

The Uniform Bill of Lading.

The Philadelphia *Manufacturer* calls attention to the victory just now won by the National Transportation Association (an association of shippers) in a contest with the railroad companies against a proposed invasion of shippers' rights. The railroads lately prepared a uniform bill of lading, which they tried to compel the public to accept. This bill of lading contained many clauses of an unfair character, as, for example, one that relieved the transportation companies absolutely from all liability for goods damaged or destroyed by the negligence of the companies' servants. It also had printed across the face of it in large letters the word "non-negotiable," and it made new classifications of freights directly to the advantage of the carriers and against the advantage of shippers. Well-informed persons have fully understood that a bill of lading of such a kind will not stand the test of submission to a court of justice. But the great mass of shippers are not well informed, and the usefulness of such a formidable document to the companies lay in the fact that it might be used to frighten and discourage ignorant, timid and poor men from pressing just claims against the companies.

The attempt to force this bill of lading into use was resisted by the National Transportation Association, of which the Manufacturers' Club is a member. That body protested to the railroad companies; but it did much more. It presented the matter to the Inter-State Commerce Commission backed by 40,000 signatures to an appeal for protection, and it even carried the case into Congress in a petition for legislation which shall make this kind of thing impossible for the future. A speedy consequence of all this active effort has been that the Chicago & Grand Trunk Railroad Company have announced at Chicago that they, for their part, withdraw from the attempt to impose on the public, and repudiate the proposed uniform bill of lading. The company have prepared a bill of lading of their own, containing a small amount of matter, phrased in plain language, and declaring themselves "subject to carrier's liability under the common law in force in the various States, Territories, Provinces, or foreign countries through which the goods may pass."

This is enough for any carrier who proposes to deal fairly with its clients. For in any case, no matter what the bill of lading may say, such matters are governed by law and are always disposed of in accordance with law when a shipper who has had damage has persistence enough to seek justice resolutely, without regard for restrictions and conditions put upon him by the carrier. The time has not yet come when American legislation will relieve public transportation companies from responsibility for valuable material intrusted to their care and for the movement of which fair prices have been paid.

The action of the Grand Trunk Railroad Company will probably cause the abandonment of the uniform bill of lading by all the companies. Competition for business is too eager to permit one line to have the advantage bid for by this concession to indignant public opinion.

The brown prismatic powder furnished by the Duponts for use in the trial tests of the 13-inch gun did not prove as powerful as expected, so that the range test of throwing the 1100-pound projectile 10 miles will not be made until a better quality of powder, having greater velocity, is provided.

Ocean steamship lines report that the number of immigrants booked by them this season is 60 per cent. less than at this time last year, and official figures show that the number entering the port of New York during the past three months was 17,767 less than in the corresponding period of last year. Dull times and strictness in enforcing the immigration laws are credited with this decline.

The recent action of the Superintendent of Canals, under authority of the New York State Legislature, in granting an exclusive 50-year contract to the Cataract General Electric Company for the transmission of electricity along the banks of the canals of the State, with the right to supply light and power not only for use on the canals, but in all the adjacent territory, has raised a storm of indignant protest in several quarters.

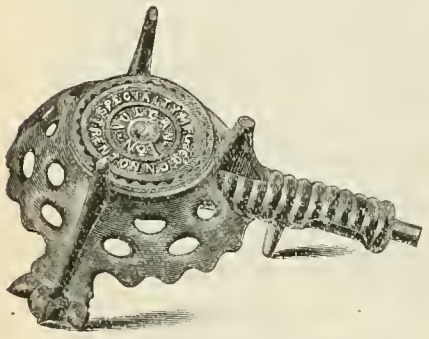
There is said to be a movement on foot among the paper manufacturers of the United States toward a great national combination, or pool, of all the mills.

Terence V. Powderly has filed a claim against the executive board of the Knights of Labor for back salary as General Master Workman.

THE RETAIL STORE.

Vulcan Gas Burner.

The Specialty Mfg. Company of Trenton, N. J., through their selling agents, James R. Steers & Co. of 42 and 44 Broad street, New York, are putting on the market the gas burner or stove shown in the accompanying cut. The burner is intended for use in bedrooms or other places where a quiet and powerful heat is required for heating water or other purposes. It consists of a malleable iron frame or stand, having a removable center piece or burner made of the same material. The supply connection is simply a pointed tube which screws into the sleeve and allows of a piece of rubber tubing being slipped



Vulcan Gas Burner.

over its outer end. The pointed supply tube connects with a passage in the sleeve of the stand and thus allows of the passage of gas to the point of combustion. Provision is made by means of the screwed supply tube for the combination of air with gas, and the combination may be regulated by screwing the tube in or out so as to get the most efficient combustion. The burner consumes but 3 feet of gas per hour, and it is claimed that the pressure required is so slight that the tubing conveying the gas may be placed over the ordinary jet burner without removing the tip. There is no gauze in the burner, and nothing to break or give out. The burner is of neat appearance, light in weight, and occupies very little space. The makers claim that it will heat a quart of water in four minutes, and is easily adjusted to any gas pressure, a turning of the supply tube until a blue flame results being all that is required.

The McKim Patent Measure.

We show in the accompanying illustrations views of the McKim iron bottom ½-bushel measure being put on the market by the Bellaire Stamping Company, Harvey, Ill. Fig. 1 is a general view of the measure, while Fig. 2 shows it with side wall cut away, revealing the top finish and the method of joining on the bottom. Special emphasis is laid upon the fact that it is made of solid steel, the bottom being fastened mechanically in a slot. This slot is formed in an ingenious manner by a series of folds in the bottom of the measure, which can be clearly seen in Fig. 2. The bottom is further strengthened by a metal foot riveted to the center of the bottom

The McKim Patent Measure.—Fig. 1.—General View of Measure.

plate, which prevents the bottom springing down, however great the pressure upon it. The measures are made of a

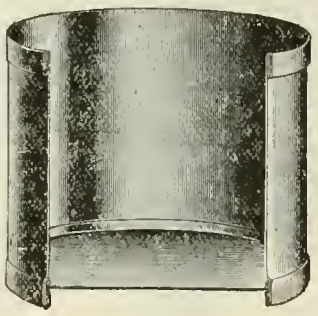


Fig. 2.—Measure with Side Broken Away.

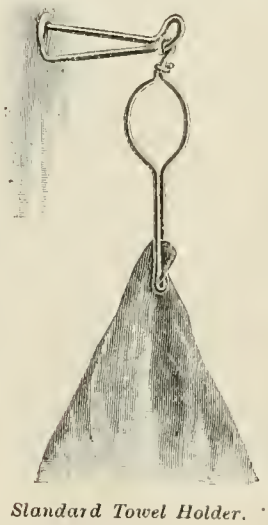
heavy gauge of metal and are thoroughly painted.

Standard Towel Holder.

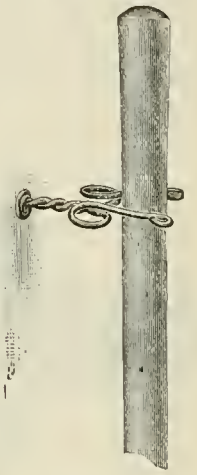
Hamblin & Russell Mfg. Company, Worcester, Mass., are putting this article on the market. It is represented in the illustration herewith given, which indicates its construction and the manner in which it is used. The holder consists of two parts, each of which is made of one continuous piece of steel wire. One of the parts is screwed in the wall or partition, the other part or holder proper being suspended from it. The holder is neatly nickeled.



Standard Towel Holder.

Standard Broom, Brush and Tool Holder.

This device is being put on the market by the Hamblin & Russell Mfg. Company, Worcester, Mass., and is shown in the accompanying illustration, which represents its shape and use.

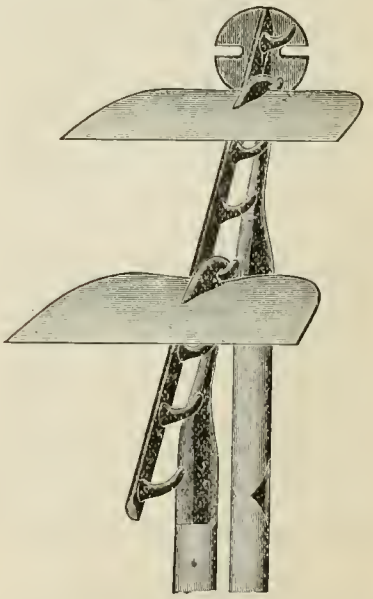


Standard Broom, Brush and Tool Holder.

The holder consists of two steel wires which are twisted together in the manner shown. The end of one of the wires is threaded to act as a screw in securing the holder in place. The holders are made tinned and nickeled.

The Hager Hoe Bracket.

The cut here shown represents a hoe bracket being introduced by John N. Hager, Fort Atkinson, Wis. The



The Hager Hoe Bracket.

bracket is provided with eight hooks, and is described as convenient for hanging up the hoes or taking them down without one hoe interfering with any of the others.

STOVE TRADE NOTES.

The Local Stove Trade.

The stove trade in New York and vicinity during the month of March showed a decided improvement over that of February, and more nearly approached the normal volume than at any time for five or six months past. The atmosphere in the wholesale houses was more charged with business; there was more general activity in nearly all departments; more correspondence, more requests for quotations, more callers from among the dealers, and the quiet and hush that characterized the first two months of 1894 in the stove business and made the business days more like a succession of Sundays was gone—it is hoped never to return, while with the dealers themselves there was less gloom, and instead of the almost automatic shake of the head when the salesman called there was something they needed and ordered.

The repair business, which naturally commenced last fall to increase when the traffic in stoves declined, is now falling off, due largely, of course, to the departure of cold weather, but likewise due in part to a return of confidence among those who can afford to throw the old stove away and purchase a new one. There is nothing in the present increased demand to encourage any hopes of an approaching boom, and nothing to warrant the expectation of large dividends at the end of the year in the stove line, for prices are low and have been cut to an unprofitable point. Many sales have been effected by wholesalers accepting offers made by dealers who know what a bargain is and can afford to hold the goods awhile if necessary. Some orders, too, have been complimentary to the drummers, and did not indicate particular revival of trade with those who gave them. Again, a large percentage of the output of local foundries for March was made on orders from abroad and for new buildings, still leaving, as will be seen, a limited local demand for the smaller portable cooking constructions. But in this line improvement was also noted, and city dealers ordered by the dozen, instead of one or two at a time, as they had been doing since December 1.

The deficiency in demand appears to be settling down to the actual point where the non-employment of working men—those who depend for a living entirely on daily wages—affects trade, and shows less timidity among the middle classes and those who have money saved. This is apparent from the orders, postponed for many months, that are being placed to renew or alter furnaces or heaters or for other changes in the heating plants in private residences.

The most encouraging sign that the revival is genuine and will soon reach the poorer classes, naturally the last to benefit by a return to prosperous times, is the fact that renewed activity in building is taking place in the cities hereabouts on a satisfactory basis, even better than has existed for two or three years past. Many well-known representative and monied men who have been missed from the field for two years or more are making their reappearance and preparing for large operations. The architects' tables are full of plans, the builders' mercantile agencies are becoming active with inquiries about builders whose past records are gratifying to those who inquire, and the agencies are receiving many visits from regular builders who call to announce their intention of undertaking building operations and to make statements of their financial condition.

The speculators are relegated to the rear and an era of healthful prosperity in this line seems at hand. As it is the great mainspring of business, it contains great encouragement and must give employment to thousands of men whose demands on the stove dealers as well as many others will soon compel the employment of other mechanics to supply their wants. Thus the snowball of trade is started on its way, growing in circumference with every turn.

The reason for this activity in building when commercial business generally is but just emerging from such great prostration is plain, for builders realize that values cannot be much lower than at present, and no more favorable time could be expected in which to make contracts. The effect of tariff changes has been discounted and competition from worthless speculative builders is not to be feared. While some materials may go a little lower, everything has nearly touched bottom, and with the last decline reaction is sure to come and the rebound would carry prices above the present market.

It must be borne in mind that the weather during March was very favorable to business, and some portion of it may have been borrowed from April, so that the volume of business this month may be somewhat disappointing, but the fact remains that city trade is on the up grade, and combining the months of March and April, a smaller percentage of decline compared to the same months of 1893 will undoubtedly appear than a comparison for two years of a combination of January and February would show. Very few new patterns of ranges have been brought out this spring, and under the circumstances but few were expected by the dealers.

SIFTER.

The Art Stove Company

of Detroit, Mich., have just issued from the press a new catalogue which is a credit to their taste and understanding of what dealers require in the way of trade literature. It is substantially bound in board covers, is printed in black upon a good quality of calendered paper and is of a size and shape to facilitate reference. The edges of the pages are tinted in a color to form a pleasing contrast with the shade of the cover. The opening pages are given up to various matters of general and specific interest to the dealer, while the body of the work contains illustrations and descriptive matter relative to several lines of new goods. Among the latter may be mentioned the Laurel steel range, embodying the latest improvements and made in a variety of styles and sizes; the Home Laurel six-hole range, made for hard or soft coal, coke, wood or natural gas, and the Family Laurel range, made with four and also with six boiler holes. These goods are referred to as first class in all respects and as embodying those features which render them satisfactory in operation. The ornamentation is of a high order of merit, the nickel plated portions forming a pleasing contrast with the black iron surfaces. In the way of cook stoves the company have added to their assortment the Family Laurel, a four-hole construction provided with duplex or shaking and dumping grate, new and improved hearth, patent oven door opener, large ash pan, ventilated oven and interchangeable reservoir, so that a square stove can be converted into a bracket reservoir stove if desired. The Peerless Laurel six-hole wood range is another new line which the company have brought out in a variety of styles and sizes The makers refer to the Peerless Laurel as "one of the most complete lines ever offered in wood burning ranges, constructed in such a manner as to give the highest possible results." A number of pages are also given to heating stoves known under such names as Radiant, Novelty, the Parlor Laurel, the Oakland, the Cannon Laurel, the New Oak, Monarch Laurel and the Cottage Laurel. The catalogue closes with illustrations of an interesting line of oil heating stoves known under the names Art Laurel and Combination Laurel, followed by a line of improved lamp stoves. The catalogue is neatly arranged throughout and closes with an alphabetical index. The company are doing a good business in their specialties and state that they are running their works full capacity.

ODD PLATES.

SOME OF THE NEW THINGS of the Boynton Furnace Company, 207 and 209 Water street, New York, are the Lakewood range and the Revertible Flue Steel Dome furnace. The range is of the double oven variety and presents a handsome appearance with several attractive features. The bottom plate is of cast iron, having the flue strip as part of it, and can be lifted out, so that the flue can be readily cleaned. The bottom of the oven flue is covered with a non-conducting coating. The water back bears a label stating that it has been tested so stand 100 pounds pressure, and is novel in shape. It lies at the back and inclines toward the front, and extends for a short distance along each side of the fire chamber. A revolving grate and an ash sifter below makes a convenient fire chamber equipment. The range is furnished with either a handsome base or a hot closet under each oven. A nickeled front hearth in one piece extending across the range is a new ornament. The furnace has a substantial base, a capacious ash pit and a lever shaking center dump grate. A cast

iron fire pot supports a large steel dome of heavy plate and gas proof construction. From the sides of the dome two indirect draft columns of steel plate turn down and connect with a crescent shaped flue at the bottom. This crescent flue has at the back another steel column, which connects at the top with both the smoke pipe and the steel dome, a damper in the connection making the furnace either direct draft or revertible flue. A connection between the crescent flue and the back of the ash pit controlled by a damper affords an efficient dust flue and check damper. The casing rings are made for the use of an inner and outer casing.

THE UNION IRON WORKS of Spokane, Wash., contemplate adding a new and larger size to their line of box heating stoves, intended for use in country school houses and railway stations. The following squib is from a local paper of recent date: "Owing to the non-payment by the city for the heat supplied by the Hotel Spokane to the Mining Exchange the steam was turned off recently, much to the discomfort of the visitors and those engaged there As there seemed no chance of an immediate settlement of the trouble Harry E. Curtis, proprietor of the Union Iron Works, kindly donated a large stove to the exchange, and the mercury has again risen to a comfortable degree. The stove donated is a simon pure Spokane product, and is as good a heater as is made in any other part of the country, being especially adapted to heating offices."

JOHN F. BANNON, assignee of the Security Gas & Vapor Stove Company of St. Louis, Mo., has recently disposed of the property to L. B. Jones, who, we understand, intends, with a large working capital, to immediately put the plant into active operation. It is stated that the property sold for more than enough to pay 100 cents on the dollar to the creditors, thus leaving something for the stockholders. It is intimated that Mr. Jones will erect a large factory on the line of the railroad, and thus be in a position to enjoy exceptional shipping facilities.

THE FLORENCE STOVE WORKS at Florence, Ala., were sold on Thursday, March 22, by the trustee of the old land company to H. Thoele and associates. We understand the plant will be put in good condition, and as soon as the work is completed will be actively operated.

THE KEELEY STOVE COMPANY of Columbia, Pa., commenced on Monday, March 26, running five days in the week. For some time past they ran but three days in the week.

THE CORNING STOVE WORKS, located at Corning, N. Y., are now in full operation and running full time.

THE BRAMHALL DEANE COMPANY of New York City were incorporated last week, with a capital of $300,000, for the purpose of manufacturing cooking, heating and ventilating apparatus. The directors are Royal E. Deane, George G. Brooks and George Rawlins of New York City.

THE ROGERS STOVE FOUNDRY, at Belleville, Ill., resumed operations on Tuesday, March 27.

THOMAS FLETCHER, the well-known English manufacturer of gas stoves, in reply to some adverse criticism, writes to the *British Medical Journal* relative to cooking by gas. Among other things he says that for heavy and continuous use, both fuels being used with equal economy, 1 pound of coke or coal is equal in heating power to about 19 cubic feet of ordinary coal gas, the actual comparative cost depending upon local prices. For irregular work, such as cooking, he says that gas is in price a far cheaper fuel than coke or coal.

THE DANGLER STOVE & MFG. COMPANY of Cleveland, Ohio, have recently issued from the press a very attractive catalogue of the Dangler gas stoves and ranges for the season of 1894. The frontispiece consists of a bird's eye view of the company's works, followed by an announcement to the trade in which it is stated that during the season of 1893 their business showed a very large increase over that of any previous season. The 48 pages of which the catalogue consists carry illustrations of a varied line of gas burning appliances adapted for heating and cooking purposes. The descriptive text is of such a character as to inform the dealer as to the special features embodied, while the engravings are specially fine. Cabinet gas ranges, shown with and without connections for hot water boiler, occupy the early pages, following which are junior stoves, hot plates, ovens, burners, water coil attachments, &c. The Dangler radiator occupies several pages, as does also the Dangler cylinder heaters. The little volume is carefully arranged, neatly printed and bound in colored paper covers, with side title embossed in black and old gold. A telegraphic code is a valuable feature of the work.

THE MOUNT PENN STOVE WORKS have purchased the stove business of George Uniacke, 111 and 113 North Second street, Philadelphia, formerly carried on by Thos. Holt, and more recently by Naylor & Uniacke, and will in future conduct it in their own name, carrying a complete line of goods. They propose also to keep in stock the usual line of stove dealers' goods, including gas, gasoline and oil stoves and ranges, vapor torches, plumbers' soldering pots, refrigerators, hollow ware, tinned and enameled ware, farmers' boilers and kettles, mica, stove polish, fire brick and furnace and stove repairs. The store will be in charge of George Uniacke.

WM. HIGHTON & SONS, 55 Charlestown street, Boston, Mass., have taken the agency for the line of furnace fittings made by the Excelsior Steel Furnace Company, Chicago, and in addition to a full line of samples will carry an assorted stock, a feature of which will be oval goods to suit that market.

SECRETARY JOHN A. HAHEN of the Excelsior Steel Furnace Company of Chicago was in New York this week calling on the trade in the interest of their line of furnaces.

WE ARE INDEBTED to the Eclipse Stove Company of Mansfield, Ohio, for a copy of a neatly arranged catalogue illustrating and describing their Premier Eclipse six-hole range. This stove is of substantial appearance, handsome ornamentation and embodies the latest improvements. The castings are described as smoothly finished, the fitting first class and the trimmings of a high order. The range is made two sizes for wood and two sizes for coal or wood. The engravings in the pamphlet are well executed, clearly showing the features of ornamentation, while the descriptive text is of such a character as to give the dealer all necessary information. The last page of the pamphlet contains a request to those interested to write for a copy of their catalogue and discounts on their entire line of Eclipse stoves and ranges.

A CITIZEN OF WESTERN PENNSYLVANIA, residing in Sharon, recently ordered a stove from the foundry in that place, presumably that of Graff & Co., proprietors of the Sharon Stove Works. The customer was somewhat in a hurry for this piece of kitchen furniture, but desired it made especially for him and a record kept of the time consumed from the melting of the pig iron to the starting of the fire in the stove for cooking purposes. The order was taken, the pig iron melted, the cast made, the parts assembled, put together, polished, and the stove delivered at the house of the purchaser in just six hours from the time of beginning operations.

OUR READERS will remember that some time since we mentioned in these columns the fact that a relief fund had been started in the city of Detroit for the needs of the worthy suffering from the extreme business depression. It was also stated that a leading spirit in the movement was George H. Barbour, well known from his connection with the Michigan Stove Company. In a recent issue of the Detroit *Free Press* is presented a detailed statement showing the collections and disbursements, and the manner in which the fund was distributed. The receipts amounted to over $11,000, most of which was distributed by checks to the superintendents of associated charities.

WE HAVE BEFORE US a photograph of the interior of the salesroom of Sam S. Utter of 113 Beekman street, New York City. The picture shows the arrangement of the cast iron stoves and ranges, as well as that of an extensive line of oil cook stoves and heaters, in which Mr. Utter has built up a large and profitable business. Casting about for the owner of the establishment, we find him standing in the background of the picture, one hand resting upon the top of a cook stove while the other is partially inserted in his trousers pocket. The silk hat occupies its customary poise and beneath it beams the face of the genial Sam. Accompanying the photograph we have a folder for 1894, relating to the Beauty and New Beauty oil stoves. These are made in different styles and sizes, are neatly finished in nickel plate and japan and embody features of construction which have established for them a wide and growing popularity.

THE CRAIG-REYNOLDS FOUNDRY COMPANY of Dayton, Ohio, are offering the trade a new furnace known as the Triumph. It is carefully constructed in all its parts, has sectional porcupine fire pot, thus enabling the anti-clinker grate to be easily removed when desired, improved dust damper and other features on which the manufacturers base claims to superiority. The company refer to the durability, economy and cheapness of the heater, and feel confident it will prove popular with the trade.

PENINSULAR STOVE COMPANY are distributing from their Chicago office a circular stating that they are prepared to furnish customers with all kinds of stationery, the letter heads, bill heads, &c., having a lithographed heading as shown on a sample sheet which they inclose. The sheet also indicates the quality of the paper used, the dimensions of the various kinds of stationery

which can be supplied, and the prices for the same in 500 and 1000 lots.

It is reported that wages have been restored at Wood, Bishop & Co.'s foundry at Bangor, Maine.

The Schaab Puff Stove Company of 519–521 Locust street, St. Louis, Mo., have issued their first catalogue illustrating and describing the Empire stoves and ranges, which they manufacture. The steel range made under this name is constructed in a substantial manner, embodying the modern improvements, and is offered in several sizes. It is shown in the catalogue with and without connection with hot water boiler. The company also call attention to the Prize Empire four-hole coal range, the Home Empire four-hole cook, adapted for burning coal and wood, the Popular Empire four-hole cook stove, the Prize Empire wood range, the Farmer's Pride wood cook, and the Hero. The heating stoves include the Radiant Empire, Oak Empire, Floral Empire, New Twilight, Telephone and the Rose. The company are general agents for Dangler gas and gasoline stoves, Palace King furnaces, North Star refrigerators, as well as various lines of hollow ware, &c.

Edward Carton, president of the Carton Furnace Company, Utica, N. Y., was a visitor in New York City this week.

The Novelty Mfg. Company of Jackson, Mich, have brought out an entire new line of oil cooking stoves for the season of 1894. The line is put on the market under the style of Splendid oil cooking stoves. They resemble in appearance some styles of gasoline stoves, having a steel frame supporting a square steel top of commodious size, in which are inserted the usual cooking grates. The lamp is supported in the lower part of the frame work, while the reservoir is made in the shape of a horizontal cylinder, holding ½ gallon of oil, and located at the rear of the burner, so far from the lamp that it is impossible for the oil to become heated. The No. 1 stove has a single 8-inch circular burner, and is 16 inches high. The No. 2 stove has two 8-inch circular burners, with a ¾-gallon reservoir, and also stands 16 inches high. The No. 220 has two 10-inch circular burners, with a 1-gallon reservoir, and is 30 inches high. The No. 235 stove is a three-burner step stove, having two 10-inch burners and one 15-inch burner for the step. It is supplied with two polished brass horizontal tanks, each holding a gallon of oil. The hight of this stove is 30 inches. It is of large cooking capacity, to meet the requirements of a large family. These stoves are fully illustrated and described in a neat catalogue just issued, which also contains illustrations and descriptions of the Ruby round wick lamp stove and the Twin Ruby.

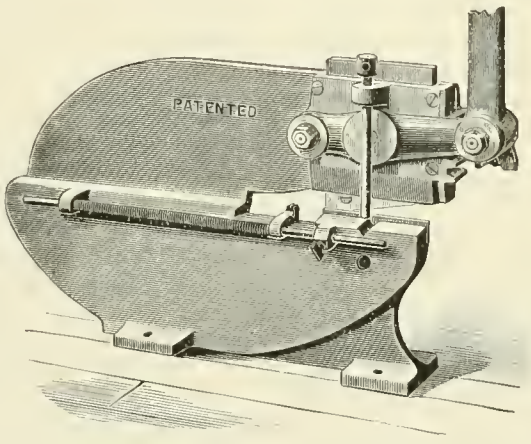
The Ingersoll Mfg. Company of Lansing, Mich., are manufacturing a lamp stove of original design which they style the Magic Room Heater. It consists of a 300 candle power lamp, mounted in a light but strong skeleton frame, which supports overhead a drum of Russia sheet iron. Inside the drum is a double cone made of thin strips of metal of a total length of 500 feet, which is termed the Ingersoll heat battery. The statement is made that with the use of this battery the heating power of the lamp is greatly increased. The heat strikes the lower apex of the cone and is rapidly absorbed by the radiating and intercommunicating strips of metal forming the battery until every part of it becomes heated, and every interstice forms an air duct or pipe through which a strong upward air current is induced which is the full size of the drum, 10 inches in diameter. The manufacturers estimate that in about six minutes a volume of air equal to the contents of a room 16 x 16 feet will pass through the battery. A grate at the top enables the lamp to be used for cooking. It furnishes light at the same time. The parts can easily be lifted out and used separately. The extreme hight of the stove is 30 inches.

The Michigan Stove Company have issued a very pretty catalogue of their Oak-Garland line of heating stoves for hard or soft coal or wood. This catalogue is printed on super-calendered paper in black and red ink, has an illuminated title page, is tied with blue silk cord and consists of 12 pages. The stoves illustrated and described are the Oakdale-Garland, an elegantly designed all cast stove, with both direct draft and reversible flue; the Syphon Oak-Garland, a base heater of original construction, giving a return flue to a boiler iron stove, and specially designed for keeping a fire of soft coal; the 1894 Oak-Garland, for any kind of fuel, in four sizes, furnished with a patented cut off grate when used for wood; the Horizontal Oak-Garland, for wood, with direct draft and revertible flue; the Oak Pennant, a lower priced boiler iron stove, intended for any fuel and made in seven sizes. The Michigan Stove Company's line, it will be seen, is so extensive as to cover every requirement for an oak stove. It embraces stoves adapted to every kind of fuel, even including chips and hay. All tastes are considered, from those who desire the most ornate constructions, rich in nickel and fine carving, down to those who are looking for something reasonable in price to compete with cannon and box stoves. It is unquestionably a magnificent line, as stated in the catalogue.

The many friends of Washington M. Shaddinger, secretary of the Detroit Stove Works, will be pleased to learn that on the 2d inst. he was united in marriage to Florence B. Borgman at Detroit, Mich. Our genial friend Shaddinger had appeared to be proof against the attractions of the fair sex, and the step he has taken is strong evidence that he must have at last encountered a lady of superior charms and far more than ordinary graces. The happy couple are "at home" at the Lexington Hotel, Chicago.

The Conqueror Sheet Iron Shear.

This shear is so designed that pieces of any length can be cut, and that the piece cut off will not bend up, but will be kept straight. This is made possible by the peculiar form of the frame, the upper half of which is set over so that it is not in line with the lower. This provides an unobstructed passage for the edge of the sheet in line with the knives. The piece being cut off also has a free passage in line with the knives on the opposite side of the frame. By referring to the engraving there will be noticed on the side of the frame, and parallel with the knives, a rod upon which is coiled a spring. This spring acts upon an arm which is free to slide on the rod and which is forced toward the knives by the spring. The arm is designed to enter between the sheet and the piece cut from it and to thereby slightly separate the two. It is evident that the thickness of the metal being cut will control the position of the arm, it being nearer the knives when the sheet is thin. The upper knife is actuated by a lever to the free end of which is attached the handle, in the end of which is a segmental gear adapted to engage a rack in the frame. This construction is extremely simple and provides ample power. This machine is made in two sizes by Chas. G. Eckstein & Co. of 41 John street, New York. No. 1 will shear $\frac{5}{32}$-inch sheet iron and has knives 5½ inches long; No. 2 will shear 1¼-inch sheet iron and has knives 6 inches long.



The Conqueror Sheet Iron Shear.

The number of vessels passing through the Suez Canal last year was 3341, as against 3559 in 1892. Of these 2262 were under the English flag. The time of transit through the canal has been gradually reduced of late years, since the aid of the electric light for night navigation has been introduced. The average length of passage last year was 20 hours 45 minutes per vessel. In 1891 and 1892 it was 23 hours 31 minutes and 21 hours 16 minutes, respectively.

The latest estimate of the mint bureau places the production of gold throughout the world in 1893 at $150,000,000. In 1892 the production was $138,860,000.

TRADE REPORT.

The Iron Market.

The condition of the market seems to be precisely as noted in our last. Manufacturers and dealers report a good inquiry and somewhat larger sales, but unfortunately that about exhausts all the favorable features. Prices are easier, and, in fact, lower on Pig Iron, while there is no perceptible improvement in Billets and Finished Material. This hardly bears out the statement that the market is better, although there is reason to believe that the tendency is in that direction, and with anything to give it a start the movement might become one of great activity. For the present, however, there is no disposition to buy anything that can be postponed until a later date, so that it will evidently require something sharp and decisive before consumers can be induced to abandon their hand to mouth policy.

The reduction in freights from Southern furnaces to points north of the Ohio River, amounting to 50¢ @ 65¢, has allowed Southern furnace agents to crowd their prices down further. To some extent, however, the reduction had already been discounted.

Pig Iron.—The New York market is quiet. The great battle ground at the present seems to be the New England market, where Virginia, Alabama, Mahoning and Shenango Valley, Eastern Pennsylvania and Buffalo furnaces are fighting for their share of the market. As yet freights from Southern furnaces to New England and to tidewater points are unchanged, but the drop of 50¢ to other sections is supposed to indicate a similar reduction to this section. Among the Cast Iron Pipe contracts about to be closed is one for about 4000 tons for Syracuse, 1500 to 1800 tons for Buffalo and 600 to 800 tons for Niagara Falls. We quote standard brands $12 75 @ $13.50 for No. 1; $12 @ $12.50 for No. 2, at tidewater. Southern Iron, same delivery, $12.25 @ $13 for No. 1; $11 @ $11.50 for No. 2; $10.75 @ $11.25 for No. 3; $11 @ $11.25 for No. 2 Soft, and $11.25 @ $11.50 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10.25 @ $10.75.

There has been a pretty fair demand for Pig Iron in the Philadelphia market, but the increased output furnished more than a full supply, the result being somewhat lower prices for all descriptions. Foundries are gradually resuming work, but at best the consumption does not average more than 50 to 60 % of what is usual at this season of the year, so that there is still plenty of margin for improvement. Among the curious changes noted in regard to the Pig Iron trade is the practical withdrawal of the Alabama furnaces from this market, and the increasing competition from Central and Western Pennsylvania. The last mentioned appear to control prices entirely, and furnaces that are unable to compete have no alternative but to stand aside. Quotations vary considerably, but as a rule delivered prices for Philadelphia and equivalent points are about as follows:

Standard No. 1 Foundry X	$12.75 @	$13.25
Standard No. 2 Foundry X	12.00 @	12.50
No. 2 Plain	11.00 @	11.25
No. 1 Soft	11.75 @	12.00
No. 2 Soft	11.00 @	11.25

Our Chicago agent reports that another disturbance has occurred in that market in the sudden reduction of freight rates on Southern Pig Iron to the Chicago market to $3 ℔ ton from the Birmingham district. This rate is very much lower than anything ever before known. It at present applies only to the immediate vicinity of Chicago, but dealers expect that, as usual, it will very shortly be made to apply to other points which have hitherto taken Chicago rates. Prices were immediately affected by the reduction, but they have not so far led to much new business. The reductions made in the price of local Irons have not been so great as on Southern, because a part of the drop had been previously anticipated. The bulk of transactions during the past week was as usual in locations in which a moderately active trade was reported, with considerable inquiry indicating an early expansion of business. Consumption is steadily increasing. The largest sale of Lake Superior Charcoal reported during the week was one of 500 tons at private terms. Freight rates to this point from Northern Wisconsin have, curiously, been advanced 25¢ ℔ ton. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @	$15.50
Local Coke Foundry, No. 1	11.25 @	11.50
Local Coke Foundry, No. 2	10.50 @	11.00
Local Coke Foundry, No. 3	10.00 @	10.50
Local Scotch	11.50 @	11.75
Ohio Strong Softeners No. 1	13.00 @	14.00
Southern Silvery, No. 1	..... @	11.50
Southern Silvery, No. 2	..... @	11.00
Southern Coke, No. 2	10.00 @	10.35
Southern Coke, No. 3	9.75 @	10.00
Southern, No. 1, Soft	10.25 @	10.50
Southern, No. 2, Soft	9.75 @	10.00
Tennessee Charcoal, No. 1	15.00 @	15.50
Tennessee Charcoal, No. 2	14.50 @	15.00
Alabama Car Wheel	17.85 @	18.00
Jackson County Silvery	15.00 @	16.00
Other Ohio Silvery	13.00 @	13.50

The troubles in the Connellsville Coke region are the prevailing feature of the Pittsburgh market. Should the strike now under way be greatly prolonged it will necessitate the blowing out of a number of furnaces, and possibly cause an advance in the price of Iron. Foundry Iron is in light demand, No. 2 ruling at $10.50 @ $10 75, Pittsburgh. Quotations are as follows:

Neutral Gray Forge	$9.25 @	$9.50, cash.
All-Ore Mill	9.50 @	9.75 "
No. 1 Foundry	11 25 @	11.50 "
No. 2 Foundry	10.50 @	10.75 "
Bessemer	10.35 @	10.50 "

There has been some increase in the volume of business in Pig Iron during the week, which is seemingly the result of lower prices to consumers at Northern points, there having been a reduction in freight rates from Birmingham to the Ohio River of 50¢ ℔ ton and to some Northern and Eastern points of more than this. This has enabled the Southern furnaces to meet the competition of Northern furnaces on a more equitable footing. As a rule, prices of Pig Iron at the furnace have not changed. No. 2 Foundry is offered at $7 ℔ ton and No. 3 Foundry $6.50, f.o.b. Birmingham. A large part of the business during the week was for Iron delivered, and as it was not expected that the reduction in freight would be so large, rather better prices were obtained than could be now realized. There has been no movement in Charcoal Iron, and prices are nominal. Some sales of Coke Iron have been made for short forward delivery at the same prices as for spot delivery. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$10.50 @	$10.75
Southern Coke, No. 2	9.25 @	9.50
Southern Coke, No. 3	8.75 @	9.00
Ohio Soft Stone Coal, No. 1	14.50 @	15.50
Ohio Soft Stone Coal, No. 2	14.25 @	14.50
Lake Superior Coke, No. 1	13.00 @	13.50
Lake Superior Coke, No. 2	12.00 @	12.25
Hanging Rock Charcoal, No. 1	17.00 @	17.50
Hanging Rock Charcoal, No. 2	16.50 @	17.00
Tennessee Charcoal, No. 1	13.00 @	13.50
Tennessee Charcoal, No. 2	12.00 @	12 50
Standard Southern Car Wheel	16.25 @	17 00
Lake Superior Car Wheel and Malleable	16.50 @	17.0

Metal Market.

Pig Tin.—Prices have undergone an advance of about 30¢ ℔ 100 lb, and the market has been very firm, although devoid of anything in the nature of speculative support. It is estimated that the spot stock in first hands is not to exceed 1200 tons. The monthly consumption is estimated at 1200 tons. Of the 1200 tons spot stock about 980 tons are in bonded warehouse. It would therefore appear that only 320 tons of Tin imported prior to the levy of the duty of 4¢ ℔ lb remain unsold. Since the duty went into effect 3326 tons have been imported. The present bonded stock of dutiable Tin is about 980 tons. On the face of

the returns it would appear that duty has been paid on about 2346 tons since July 1, 1893, and it is not improbable, considering the course of local market prices in the interval, that a loss was made on the greater portion. The market seems now to be shaping for more satisfactory results, and the movement in that direction would probably be more rapid but for the uncertainties attending tariff legislation. At the close the market was strong, with Straits quoted at 19.50¢ net, cash, for 5-ton lots, early delivery. Forward deliveries are held at a premium of 5¢ @ 10¢ per month ; 19.60¢ was paid for 1 carload. Meanwhile the requirements of consumers have not induced any marked expansion in the demand, which continues moderate. Small lots of Straits Pig are quoted at 21¢ @ 21¼¢ ℔ lb.

Copper.—Little, if any, change has taken place in the market for ingot during the past week. Business shows no improvement, and sellers have been more actively interested than buyers. Still it does not appear that this slight sign of anxiety to sell has weakened prices, although imparting somewhat uncertain tone to the market. Current quotations are 9⅛¢ for Lake Superior Ingot, 9¼¢ @ 9⅜¢ for Electrolytic and 9¢ @ 9¼¢ for casting stock. Jobbing business is correspondingly slow, the demand for both Ingot and manufactured Copper being entirely disappointing. Retail prices for small lots are unchanged at former quotations.

Pig Lead.—The market has remained very quiet, and prices have averaged somewhat lower. Further than this there are really no facts to report, except that 3 40¢ is now a quite general selling price for common Western in carload lots. Regarding supplies little is said, but it is the general belief that an accumulation at primary points has taken place during the past two weeks. Jobbers and retailers complain of extreme dullness and indifference on the part of consumers. Prices are inclined to weakness.

Lead Sheet and Pipe.—There has been absolutely no improvement in the demand for these materials. Purchasing of plumbers' supplies is on the narrowest scale possible, consumers taking nothing beyond what is required to fill immediate needs. Business compares very unfavorably with former seasons.

Spelter.—Slow business and very indifferent demand have again been experienced, leaving the market in a flat, uninteresting condition. No pressure to sell has developed, however, and prices seem quite steady at 3.80¢ for ordinary Western brands, delivered here or at common points. One car, spot, was offered at 3.75¢ on the Metal Exchange. Statistically, however, the conditions for an advance in Spelter could hardly be better. There are at present 62 furnaces in operation west of the Mississippi River, in comparison with 122 furnaces at this time a year ago. In addition to this, over 95% of the galvanizing works in the country are in operation. Stocks everywhere are light; consequently an upward turn in prices seems to be only a question of time.

Antimony.—The demand is still of ordinary type and the market bsre of new feature. Prices stand at about 8⅞¢ @ 9¢ for Hallett's and 10¢ @ 10½¢ for Cookson's. with the usual premium of about ¼¢ on small lots from store.

Nickel.—No change is reported, 40¢ being quoted as the going price.

Tin Plates.—At intervals there has been a fair trade in spot Plates and some manifestations of interest in futures; but, on the whole, the volume of business has been light in comparison with the general run at this season of the year and decidedly disappointing. Prices show no radical change, being at about the bottom level in all lines of Plates. The demand for Bessemer Cokes for the use of Southern canners, which should be exceedingly active at this time of the year, is particularly slack. This is partially accounted for by the damage done to the fruit crops and injury to growing vegetables by the recent severe weather. But tariff uncertainties have also contributed materially to restrict purchases. Canners generally are hanging on until the last moment before placing orders for what they will need this season, and they have about another month's leeway before they absolutely need to purchase. Meanwhile, stocks of imported Cokes are unprecedentedly short and but little stock is on its way to this country. Consequently, any large expansion of the demand would be difficult to meet. It is said, moreover, that the stock of Bessemer Cokes on the other side is by no means large. Roofing Plates are in fair average routine demand, which is easily met by the domestic manufacturers.

A special cable dispatch to *The Iron Age* from London, dated April 4, reports a fair business in 14 x 20 Cokes. Good orders had also been received for Black Plates. Liverpool quotations for Plates were as follows:

IC Charcoal, Alloway grade	12/ @ 12/3
IC Bessemer Steel, Coke finish	10/6 @ ....
IC Siemens " " "	11/ @ ....
IC Coke, B. V. grade, 14 x 20	Nominal.
Charcoal Terne, Dean grade	10/3 @ 10/6

V. Clad & Sons, Philadelphia, Pa., issue for the season of 1894 an illustrated price-list of ice cream machinery. The pamphlet opens with a brief description, illustrations and price-lists of a variety of different styles of ice cream machines for hand and power, this section including freezer with steam engine attachments. The next goods noticed are ice breakers and freezers. Then come a variety of supplies. It is impossible to enumerate all the goods referred to in this pamphlet, but suffice it to say that it contains a most complete list of articles of this sort.

Chicago Report.

Scrap.—Very little is being done in anything but Cast Scrap. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....
No. 2, such as Shovels, Hoes, &c	3.00	....
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5 ¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5½¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite. — Prices have been reduced 85¢ ℔ ton on the old schedule. Carload lots of 12 net tons or over are now quoted as follows:

	Grate.	Egg, Sto. and Ch
Chicago, Ill	$5.00	$5.25
Milwaukee, Wis	5.00	5.25
Kansas City, Mo	8.20	8.45
Council Bluffs, Iowa	8.20	8.45
Lincoln, Neb	8.35	8.60
Sioux City, Iowa	8.20	8.45
Aberdeen, S. Dak	8.25	8.50
Dubuque, Iowa	6.30	6.55
Madison, Wis	6.50	6.75
St. Paul, Minn	7.50	7.75
Burlington, Iowa	6.50	6 75
Des Moines, Iowa	7.95	8.20
Davenport, Iowa	6.30	6 55
St. Joseph, Mo	8.20	8.45
Leavenworth, Kan	8.20	8.45
Omaha, Neb	8.20	8.45

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.	
Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.55

The estate of S. Whitnum (E. H. Little, manager), North Eleventh street and Driggs avenue, Brooklyn, N. Y., report that the past year has been the most prosperous one they have had. The firm, who are manufacturers and galvanizers of Leader Pipe, Kitchen Boilers, Sinks and Boiler Stands, have just put in a 40-ton cupola, and have increased their galvanizing department by an additional pot, making six in all. Their plant is very complete, being some 200 feet square, and having a capacity for galvanizing articles 20 feet in length.

John H. Blood, representing John McVoy & Co. and the Midland Steel Company of Muncie, Ind., with warehouse in Chicago, has opened an office in room 1141 Monadnock Building, Chicago, for the sale of Galvanized and Corrugated Sheet Iron and Sheet Steel.

M. L. Hull of Cleveland, Ohio, directs attention in his advertisement this week to various specialties, some of the claims for which are set forth in connection therewith. The assortment includes burners of various kinds, together with Plumbers' and Tinners' Furnaces.

CONDITION OF THE

Hardware Trade.

OUR ADVICES from the trade at large indicate on the whole a continued improvement in business, and in some of the trade centers there is a very fair volume of trade. In others the reports are not quite so satisfactory, but on the whole it is evident that there is a better demand for goods, which, it is expected, will continue with some increase as the season advances. The trade are still buying very carefully and limiting their purchases to their immediate requirements. They are influenced to continue this policy by the lack of strength in the market and the lower prices which have been developed in many lines. Collections afford little ground for complaint, and the financial condition appears to be on the whole satisfactory.

Advices from Chicago.—Orders for Shelf Hardware are now increasing in amount, showing a gradual improvement in the business of the country at large. The demand held up remarkably well last week in view of the severe storms and very cold weather which prevailed throughout the entire Northwest. The proportion of straight Hardware continues to grow larger, and jobbers look forward to a good trade during April from the way in which the month has opened up. The demand for staple goods is inclined to be quiet except Barb Wire, which is moving in a very satisfactory manner. The Heavy Hardware trade kept up last week to the average for the month, and March closed with a record fully equal to expectations. The trade for April has thus far shown a slight falling off as compared with the opening of March. Collections are steadily improving.

Notes on Prices.

Wire Nails.—The Wire Nail market is in a peculiar condition, inasmuch as notwithstanding the fact that the volume of business is good and most of the mills are well occupied on orders, prices are lower and the tone of the market not strong. The price is represented by the quotation of 95 cents to $1 for carload lots at mill. The fact that such prices are named is evidence of the active competition which exists among the manufacturers and their desire to keep their mills in operation. Some orders are being received from the large trade, and a good many smaller houses are taking advantage of the low prices prevailing and find that in many instances on fair lots they can purchase more advantageously from the manufacturers than through jobbing houses. Small lots from store in New York are held at $1.20 to $1.30.

Advices from Chicago.—Not much new business is reported by manufacturers' agents. Buyers are inclined to hold off and await developments, being very well stocked for the present. Quotations from factory are a shade under $1.10, Chicago, but the general price asked seems to be $1 at factory. Freight rates vary according to the location of the establishment. Small lots from stock are now selling at $1.15 to $1.20.

Cut Nails.—The price of Cut Nails in the Eastern market is somewhat unsettled, as the desire to keep their mills in operation has had the effect of inducing lower quotations by the manufacturers than prevailed a month or two ago, and at the same time they are feeling the effect of Western competition to a certain extent. Western Nails are being offered delivered in New York and other Eastern points at 95 cents to $1 base, and it is intimated that these figures have been shaded in some cases. Small lots from store in New York are held at $1.10 to $1.15, slight concessions being made on larger lots.

Advices from Chicago.—A report was circulated widely last week that the Lake Side Nail Works had shut down for lack of orders. This report was false. The works are in full operation with no immediate prospect of closing. Manufacturers report a very fair volume of business for the week. The market, however, was disturbed by the appearance of Ohio River manufacturers, who made very low quotations in the hope of securing a share of the Chicago business. Regular rates are still $1 on 55 cent average. Small lots are quoted at $1.10 from stock.

Barb Wire.—There is little change in the condition of the Barb Wire market, the demand continuing excellent and prices being on the whole well maintained. The regular quotations of the manufacturers are as follows on Four Point Galvanized: Pittsburgh, $2.15; Cleveland, $2.20; Cincinnati or Allentown, $2.25; Chicago or New York, $2.35.

Advices from Chicago.—Nothing new has occurred in this line. Manufacturers appear to be in excellent shape, with sufficient business on hand and daily being received to hold prices up to the figures recently quoted and maintained. Carload lots of Galvanized are selling at $2.25 to $2.30, and small lots from stock are quoted at $2.35 to $2.40.

Cordage.—The Cordage market is in an unsettled condition, and lower prices have been developed. Last week a leading outside concern made a quotation of 6 cents base on Manila Rope, which had the effect of bringing down the prices of other manufacturers, some of whom are selling at this price, while others refuse to name lower than 6¼ cents. The latter figure is regarded as representing the market at this time, though it is intimated that slight concessions may be obtained. Sisal is being sold at 4¼ cents base, and there is little difficulty in obtaining the goods at this price. New Zealand is also quoted at 4¼ cents base. Rumors are current in regard to impending changes in the management of the United States Cordage Company, and it is understood that negotiations are still pending with a view to the identification of the Good interests with those of the company. What the outcome may be is uncertain, but it would not be surprising if there were some developments of interest within a short time.

Stove Bolts.—The base discount on Flat and Round Head Stove Bolts has been made 65 per cent. instead of 60 per cent. as heretofore.

Bay State Rivets.—In their discount sheet, April 2, American Screw Company, Providence, R. I., quote Bay State Rivets ¼ cent net per pound less than Norway Rivets, instead of by list and discount as heretofore.

Sheet Zinc.—Under date March 27, Matthiessen & Hegeler Zinc Company, La Salle, Ill., issue revised discounts on Sheet Zinc. The price remains $4.50 per 100 pounds in 600-pound casks, of the thicknesses between Nos. 9 to 15, inclusive, and of the widths between 32 to 46 inches, and of the lengths between 84 to 90 inches. The extras are also unchanged. The revised discounts are as follows:

Discounts.	First class. 15 600-pound casks and upward.	Second class. 10 to 14 600-pound casks.	Third class. 5 to 9 600-pound casks.	Fourth class. Under 5 600-pound casks.
	Per cent.	Per cent.	Per cent.	Per cent.
Special	9	9	9	9
Cash with order	3	3	3	3
Quantity	3	2	1	0
Totals	15	14	13	12

All discounts are computed straight when money accompanies the order. Quantity discount is added to special discount in all cases. If remittance is received within 10 days of date of invoice the cash discount will be only 2 per cent. instead of 3 per cent., and not computed straight. Each order is strictly subject to the quotation of the class to which it belongs.

Furnace Fittings.—Under date of April 1, 1894, the Carton Furnace Company, Utica, N. Y., and Chicago, Ill., issue a special net trade price-list of Furnace Fittings. These Tin Plate Fittings, they announce, are made of best quality of IX prime, full weight, charcoal bright Tin Plate, and the Gal-

vanized Iron Fittings are made of best Bloom Galvanized Iron. All are hand made. We reprint below the prices on Round Hot Air Pipe, Register Boxes and Elbows:

Round Hot Air Pipe.

Inch.	Per foot.
7	$0.10

18	.95

Prices are also given on Square Pipe, hot air; Square Pipe Elbows, regular; Square Pipe Elbows, flat; Square Pipe Tees, regular and flat; Square Pipe Offsets, regular and flat; Boots, regular pattern, flat back; Boots, center pattern, round; Boots, offset; Floor Register Heads; Side Wall Register Heads, square and circular top; Double Side Wall Register Boxes, square and circular top; Furnace Collars for flat and pitch casing tops; Hot Air Pipe Dampers and Clips, Safety Thimbles, Galvanized Iron Smoke Pipe, Galvanized Iron Smoke Pipe Elbows; Check Damper Tee Pieces, Galvanized Iron; Common Smoke Pipe Dampers and Check Dampers, Cast Iron.

These Fittings are also furnished, covered with the best quality of asbestos paper, for 20 per cent. additional to the net prices. Terms are net cash, 30 days from date of invoice. No discount is allowed at settlement.

Yates' Astringent Lacquer.—Yates & Co., Rockford, Ill., are furnishing Yates' Astringent Lacquer to dealers for making paste stove polish in large or small quantities and at a very low price; also avoiding the trouble with the variation that may occur in the quality of paste polish after it has been in a can any length of time. The point is made that a dealer can thus mix, without heat, any grade of paste polish in a short time, saving the cost of manufacturing, canning and packing. It is pointed out that the lacquer can be used for making liquid stove polish, rust proof varnish, rust proof paint for roofs, soldering flux, &c. The lacquer is put up in from 2 to 10 gallon cans, and sold at the following net prices:

	Per gallon.
2 and 3 gallon cans	$1.25
5 and 10 gallon cans	1.00

Glass.—If there is any change in the condition of the Glass market, it is encouraging for manufacturers rather than otherwise. Local jobbers report a fair business for the month of March and a tendency toward firmer prices. There is a feeling among representative manufacturers and jobbers that the prices which have ruled for the past month or more should not continue indefinitely. This is indicated by a rather informal meeting of Glass men held at Pittsburgh a week or two since, at which the situation was reviewed; also by a meeting recently held at Marion, Ind., by Glass manufacturers. While the objects of the meetings were not divulged, it is understood that the discussion related to existing prices. It is also understood that the Western manufacturers met entirely independent of those of Pittsburgh or other Glass districts.

Old Metals.—There is rather more business doing in Old Metals, but it is on a strictly conservative basis. Prices continue low. In the case of some grades of Scrap Iron, however, it is said that dealers have been able to get a little more money. Inquiries are somewhat more numerous. The following quotations represent dealers' purchasing prices in New York:

Heavy Copper	℔ lb	7¢
Light and Tinned Copper	℔ lb	6¢
Heavy Brass	℔ lb	5¢
Light Brass	℔ lb	4¢
Lead	℔ lb	3¢
Tea Lead	℔ lb	2½¢
Zinc	℔ lb	2¼¢
No. 1 Pewter	℔ lb	13¢
No. 2 Pewter	℔ lb	6¢
Wrought Scrap Iron	℔ gross ton	$7.50 @ $8.50
Heavy Cast Scrap	℔ gross ton	7.00 @ 8.00
Stove Plate Scrap	℔ gross ton	4.00 @ 5.00
Burnt Iron,	℔ gross ton	3.50 @ 4.00

Old Rags, Paper, &c.—Prices for these materials show but little improvement, and the demand does not broaden to any extent. Quotations are nominally as follows:

No. 1 White Rags	℔ lb	3¼ @ 3½¢
No. 2 White Rags	℔ lb	2¼ @ 2½¢
Mixed Rags	℔ lb	3¼¢
Blues and 3ds	℔ lb	1 @ 1¼¢
Hard Sized White Shavings	℔ lb	2¼ @ 2½¢
No.1 White Book Shavings	℔ lb	2 @ 2⅛¢
No.2 White Book Shavings	℔ lb	1 @ 1⅛¢

Hemp Twine	℔ lb	2 @ 2¼¢
Manila Rope	℔ lb	2¼ @ 2⅝¢
Jute Rope	℔ lb	1½ @ 1¾¢
Mixed Rope	℔ lb	¾ @ ⅞¢

Old Rubber.—The market for Old Rubber shows some improvement, but prices are somewhat irregular. The following quotations represent approximately those given by dealers in this city:

Car Springs, ton lots	℔ lb	@ $0.03½
Rubber Shoes, carloads, delivered at factory	℔ lb	@ .03½
Rubber shoes, less than carloads	℔ lb	@ .03¾
Large Hose,	℔ ton	@ 12.00
White Wringer Rolls	℔ lb	@ .03¾
White Syringes,	℔ lb	@ .03¾

Trade Notes.

The Union Soapstone Works, 14 Marshall street, Boston, Mass., issue circulars illustrating and giving prices of their various Soapstone articles. The cuts show Laundry Tubs, Sinks, Drainboard Sinks, Foot Warmers, Griddles, &c. Full lists of sizes and prices accompany the illustrations.

Among the manufacturers who have given special attention to perfecting the quality of Galvanized Sheet Steel Ware are the Geuder & Paeschke Mfg. Company, Milwaukee, Wis., whose trade in this line has extended all over the United States. The goods are made of Sheet Steel of the best quality, and after the articles are completed they are immersed in a bath of molten slab zinc, which effectually closes all seams and makes the ware proof against rust and leakage.

The Star Milk Cooler Company, Haddonfield, N. J., have shipped to Stephen Francisco, Caldwell, N. J., the largest Milk Cooler that they have ever built. The apparatus is 11 feet high, 6 feet 6 inches wide and weighs 1000 pounds. It has a capacity to reduce the temperature of 20 quarts of milk per minute from 98° to within 2° of the spring water used as the refrigerant, which is forced through the machine by a steam pump. This Cooler was selected by a number of the leading physicians of Newark, East Orange and Orange, to co-operate with the Board of Health of Newark to improve the condition of the city's milk supply.

Kieckhefer Bros.' tinware factory in Milwaukee, Wis., was slightly damaged by fire on the night of the 28th ult. While the loss was trifling and the fire caused no interruption to business, it was attended with a most lamentable accident. When it had been extinguished, the body of the night watchman was found in the japanning room. The supposition is that he was knocked senseless by an explosion, and was then suffocated before the firemen discovered him.

Donlon & Miller Mfg. Company of Brooklyn, N. Y., were incorporated at Albany last week, to deal in gas and electric fixtures. The directors are John Donlon, Arthur S. Miller, John F. Miller of Brooklyn, and others. Capital, $50,000.

The city of Niles, Ohio, has voted $10,000 for the purchase of a site and for a bonus to the new Sykes sheet mill to be built there at a cost of $100,000, and to employ 75 men. They will manufacture sheets for roofing purposes.

Repairs on the sheet mill engine being completed, the mills of the Reeves Iron Company, Canal Dover, Ohio, have resumed operations.

It is announced that the sheet mills of the Newport Rolling Mill Company, Newport, Ky., will resume operations this week after a shut down of several weeks. The heavy assorted stocks usually carried by this company have been depleted and a steady run is expected.

Reports are current to the effect that Raymond G. Sykes of Niles, Ohio, and

James Ward of Newcastle, Pa., are interested in the project to start the sheet rolling mills at Joliet, Ill.

WHILE MANY BELIEVE that an early return to the normal conditions of business is improbable, yet there are concerns who find much encouragement in the outlook for the near future. The E. W. Bliss Company of Brooklyn are erecting in their works two of the largest and heaviest presses which they make—viz., their Nos. 14 and 15 Toggle Drawing Presses. The former weighs about 140,000 pounds, and is driven by an engine attached to it. It is about 14½ feet in hight and has a width between the uprights of 54 inches and will draw articles up to 11 inches in depth. It can be started or stopped at any point in the stroke by means of a friction clutch. These Presses are used in drawing up such articles as kitchen boiler heads, cylinders, steel sinks, heavy black iron and enameled ware. The press is to be shipped in about a week to England to be used in drawing up heavy steel shells. The No. 14 Press is somewhat lighter, weighing about 75,000 pounds, having a distance between the uprights of 30 inches, and will draw articles in depth up to 10½ and 12½ inches. This Press, while it will draw articles of greater depth, has not the requirements for doing nearly as heavy work as the No. 15 Press. This Press is being built for one of the large tinware stamping concerns in this country for drawing up heavy enameled iron ware of various descriptions.

E. T. BARNUM, Detroit, Mich., has furnished for the Alpena National Bank, Alpena, Mich., the grill work for their newly arranged offices. It consists of flat twisted metal in square mesh, riveted at each intersection with scroll border, having scroll pickets on top. All the work is electro plated in antique copper finish.

BRUCE SMITH & CLARENCE BREWSTER, Middletown, Conn., have begun the manufacture of their recently invented Water Filter. The Filter is reversible and embodies some new features.

THE PITTSBURGH REDUCTION COMPANY of Pittsburgh, manufacturers of pure Aluminum, have fitted up a large room in the Ferguson Block in that city, in which is shown a large number of articles made of Aluminum. Cooking and other culinary utensils, toilet articles and fine art castings form a part of the interesting display.

KRAUSHAAR LAMP & REFLECTOR COMPANY, St. Louis, Mo., have removed to 2510 and 2512 North Eighth street. The specialties which they manufacture consist of Car Trimmings, Headlights, Lamps, Street Railway Brass Work, &c.

WE RECEIVE from Josiah M. Read, 63 Blackstone street, Boston, Mass., circulars of the different styles of sliding dampers manufactured by him for controlling the draft of air in pipes. Their use in connection with stoves and furnaces is commended by a number of testimonials.

A substantial find of gold is reported from Virginia, a town in the Mesaba range, St. Louis County, Minn. The discovery is said to have been made accidentally while explorations for iron ore were being conducted on property owned by P. J. McCann. West Superior capitalists have become interested in the matter.

SCRAP.

THE PHILLIPS TIN PLATE COMPANY, Philadelphia, are putting in a new tinning machine of the Phillips type specially for best and ordinary coke finish plates. This will make an equipment of five sets, three of which will be employed on ternes, one on best charcoal tins and one on best and common coke finish tin plates. The firm are also adding to their plant a new and economical automatic pickling machine built by Newbold & Son of Norristown, Pa.

NORTON BROTHERS, manufacturers of tin and sheet metal goods, whose Chicago factory was recently burned, have decided to concentrate their manufacturing operations at Maywood, Ill. They require much greater facilities than they now have at that place, and propose to add considerably to the plant. The new building will probably cost $200,000 and will be located on the south side of the Northwestern Railroad and extend from Sixth to Eighth or Ninth avenue. Plans for the new structure have been completed by Frederick R. Schock, and bids for its construction are being received. The building will be constructed in the shape of a hollow square covering an area of 243 x 243 feet, two stories high. It will extend to a depth of 72 feet to an inner court, and in center of this a boiler house, 30 x 40 feet, will be constructed. In this court will be a one-story section on both sides of the boiler house for the use of employees. On the side of the main structure there will be an annex 21 x 155 feet. The interior of the building will be of mill construction throughout and will be provided with elevators. The exterior will be constructed of pressed brick, relieved by stone trimmings, and will be ornamented by two towers.

THE ELLWOOD TIN PLATE COMPANY, Ellwood City, Pa., have been granted a charter, with a capital stock of $10,000. The directors are A. W. Brown, Cambridge, Ohio, H. W. Bishop, Cleveland, Ohio, and R. C. Aiken, North Sewickley, Pa.

THE CHICAGO TIN PLATE MFG. COMPANY, whose works are located at Fortieth street and Wentworth avenue, Chicago, have opened a city office at Room 583, The Rookery. All purchases of material and sales of product will in future be made from the city office. The company have made steady progress since their establishment in June of last year. They report their tin and terne plate as giving so much satisfaction that they cannot meet the demand and are therefore arranging to at once put in additional cleaning and tinning machines.

N. E. WHITAKER of the Whitaker Iron Company, Wheeling, W. Va., in association with some friends, is contemplating the erection of a tin plate manufacturing plant. The matter will, however, depend largely on the outcome of the tariff bill now before Congress. Washington, Pa., is mentioned as the probable location of the works.

A PARAGRAPH has been going the rounds of the daily press which states that a number of New York capitalists have organized a syndicate and completed plans for the erection of one of the largest tin plate plants in the country. The syndicate is said to have a capital of $300,000 to spend on the establishment of the plant, which, says the report, is to employ, when completed, 800 men. The citizens of Washington, Pa., are said to be anxious for the location of the new works in that town, and to have expressed their readiness to take shares in the concern. Inquiries made in New York elicit the fact that there is a foundation of truth in the above report, although some of the details given are premature. A number of persons of prominence in the iron and metal trades are forming plans for the establishment of a large tin plate works, but the carrying out of the project will largely depend on the course of tariff legislation. The place of location is not, however, yet decided on, nor have any definite plans been yet completed.

It Is Reported—

Delaware.

That J. H. Cleaver, late of the firm of Cleaver & Hearn, Stove dealers, Wilmington, has opened a store with a full line of Stoves and Tinware at 6 East Fourth street.

Illinois.

That J. B. Watson's Hardware store at Barry was destroyed in a large fire at that place March 30.

That Boutwell & Schad have recently opened a new Hardware store at Lake Villa.

That Patterson & Moss, late of Danville, have leased two large rooms in the Haworth Block, Decatur, where they will establish a wholesale Hardware house, carrying a stock valued at $25,000.

Indiana.

That the H. Lundt Hardware & Roofing Company have recently commenced business at Hammond.

Indian Territory.

That the Turner Hardware Company, Muscogee, have commenced the erection of a large new building, which they will occupy on completion.

Iowa.

That Smith Bros.' Hardware store, at Sheldon, was damaged by fire on the 21st ult.

That E. S. Carson has entered the Hardware business at Lacona, having purchased one of the Hardware stocks at that place.

That C. E. Foster, lately of Stanbury, Mo., has located at Cincinnati, where he will engage in the Hardware and Implement business.

That Bailey & Ford is the style of a Hardware firm recently formed at Duncombe.

That L. Parrish recently disposed of his interest in the Hardware business, at Glenwood, to his partner, Frank Gigray, and is now traveling for a dry goods house.

That the Implement store of Carter & Shakers, El Dora, was destroyed by fire on the 19th ult.

Louisiana.

That the capital stock of the C. A. Brusle Hardware Company, Plaquemine, has been increased from $10,000 to $25,000.

Maine.

That Alger Munsey has opened a Stove and tinsmith store at Wiscasset.

Michigan.

That Adam Wagner has opened a new Hardware store at his old stand at Utica.

That Jilbert & Lang will soon open a new Hardware store at Houghton.

That Mr. Gray of Leonidas has purchased G. Baldwin's Hardware stock and is now conducting the business.

That Frank E. Hixson of West Bay City has purchased the interest of Asa Newman in the Hardware firm of Newman & Kennedy, Portland, and the style of the firm has become Kennedy & Hixson.

That A. D. Banker, Grand Blanc, has sold a one-half interest in his Hardware and Implement business to Charles M. Stuart, The business will hereafter be conducted under the style of A. D. Banker & Co.

Minnesota.

That Andrew Byram of Redwood Falls will soon enter the Hardware business at Austin.

That Henry Nelson has purchased the Hardware stock of P. Lier, Ashby.

That A. E. Johnson has bought the Hardware store of A. B. Hansen & Co., on Second street, Hastings, and will hereafter conduct the business under his own name.

That thieves entered the Hardware store of Otto Kaupp & Son, Blue Earth City, on the 18th ult., and breaking open the safe abstracted $15 in cash and a gold watch. A drawer in the safe containing $90 was overlooked.

That the large fire at Cokato on the 20th ult. destroyed the Hardware store of P. O. Hamburg; loss, $6000; insurance, $3000.

That Schneider Bros. have opened a new Hardware store at Adams.

That Horn Bros. of Delavan have sold their Hardware store to Shoen & Herring.

That Newton & Parks have disposed of their Hardware stock at Tracy to D. H. Evans.

That H. O. Monson & Co., Hardware merchants of Wheaton, have gone out of business.

That B. F. Turnbull will soon open a Hardware store at Rainy Lake City.

That Bronson & Son of Luverne have disposed of their Hardware and Farm Machinery business to Elmer Huntington.

Tin Plate Production.

Col. Ira Ayer's special report of the production of tin and terne plates in the United States for the quarter ended December 31, 1893, an abstract of which is printed in another column, presents several features of interest in connection with this industry. Although the aggregate output of plates —27,357,241 pounds—was but little over 200,000 pounds in excess of that of the previous quarter, it should be borne in mind that the last quarter of the year was one of unusual depression, bordering on panic to all the industries of the country. In this depression the sheet metal trade took its full share; and that the tin plate manufacturing industry not only held its own during that disastrous quarter, but even exceeded the output of the previous three-monthly period, is cause for congratulation. It is an indication of underlying strength which is quite significant. Had the then condition of things been normal, there is no reason to doubt that the tin plate industry would have shown a remarkable step in advance in the last quarter of 1893. On this account the report must be taken as a satisfactory one.

American Black Plates.

But a further source of satisfaction is shown in the increasing ratio of American black sheets, lighter than 63 pounds per 100 square feet, produced and used for tinning. The rapid development of the production of these sheets is clearly shown in the tables presented. The total output of black plates for tinning purposes, according to the sworn statements of 17 firms, was 19,679,910 pounds, as compared with 11,355,368 pounds in the former quarter. Of this total 90 per cent. belonged to the lighter class, as against a proportion of 72 per cent. in the September period. Then again, out of 39 manufacturing concerns the proportion of firms using entirely the American product has increased to 21, while 12 more use domestic plates in part. The aggregate output of tin and terne plates made from American black sheets, and, therefore, being American plates in the strictest sense of the term, increased in the December quarter to 15,907,669 pounds, against 11,443,572 pounds made from foreign black plate, or about 58.16 per cent. of the whole. These figures are, as we have said, interesting, as showing that even the fear of tariff changes and the universal trade depression of the latter part of last year, were not operative in depressing this industry to any appreciable extent.

Machinery in Sheet Metal Working.

Probably no field of mechanical industry has been more completely transformed in its methods and in its commercial importance by the increasing use of machinery than sheet metal working. In coppersmithing, it is true, old time methods still prevail to a considerable extent, but in the working of sheet iron, tin plate, sheet brass, &c., in which individual parts are joined by seaming, riveting, soldering or brazing, the largest proportion of all the operations is performed by machinery. Even the soldering of a large number of articles now made of tin plate is done by machines. No doubt the reasons why the coppersmith's art has not shared to an equal extent the revolution thus effected in other branches of sheet metal working are partly the fact that the principal industrial uses to which copper lends itself in the unalloyed state do not necessitate the extensive employment of numerous small pieces to be shaped and subsequently joined together, and partly the nature of the metal itself, which distinguishes it from other metals, rendering processes by which they are worked inapplicable to it in greater or less measure.

Cleveland, Ohio, Manual Training School.

The new building which is to accommodate the Central Manual Training School, in Cleveland, Ohio, was recently thrown open for use. Its interior arrangements and general design are after plans prepared by the principal, William C. Skinner, to whose unwearied efforts a large share of the credit for its erection is due. The building is of white sandstone, handsome in appearance and surmounted by a high tower. It is divided into three general subdivisions on the two main floors and in the basement, and a large number of windows afford perfect illumination to the various classrooms. Among the departments on the main entrance floor is that of wood working, which includes a pattern shop containing 25 lathes of latest design. This shop will accommodate 25 boys at one time, and four classes will be taught in a day. The machine shop, equipped with engine lathes, planers, shapers, drillers, milling machines, &c., is on the same floor. The second floor contains the carpenters' shop and drawing room, each of which will hold a class of 25 boys at a time. The smiths' shop occupies one-half of the basement, with a score of modern forges. The other half is given up to the power, heating, lighting and ventilating apparatus. The heating and ventilation are well provided for. A large fan run by a small auxiliary engine draws in the air from outside and through a screen which separates from it the particles of dust. The air is then passed through a system of steam pipes, which heat it to the desired temperature before it is sent through the building.

Evening Educational Classes for Mechanics.

The Young Men's Institute of New York, Y. M. C. A., located at 222 and 224 Bowery, New York, is an institution doing splendid educational work in the line of instruction and assistance, in both general and technical knowledge, to the young mechanics of the city, by means of evening classes. These classes are growing in importance every year. They have been found to fill, in a very satisfactory degree, the educational requirements of a large number of young men employed in various trades, who are anxious to widen their knowledge or supply the deficiencies in their early mental or mechanical training. During the season of 1893-4, just brought to a close, 635 young men have availed themselves of the advantages offered by the institute for a very small fee. These youths have had the choice of 11 different courses of study, which include such valuable practical subjects as freehand, mechanical and architectural drawing, carriage drafting, penmanship, bookkeeping, shorthand and typewriting, arithmetic, steam engineering and electricity, and it is a gratifying circumstance that so many young mechanics have embraced the opportunity. The mental and moral value of such work as is being carried on by the Young Men's Institute is obvious.

The next meeting of the Western Foundrymen's Association will take place on Wednesday, April 18, at 7.30 p.m., in rooms 702-703 Temple Court Building, 225 Dearborn street, Chicago. A paper by Thos. D. West will be read.

THE LETTER BOX.

No Place for Boiler.

From F. H. A., *Lancaster, Pa.*—Will *The Metal Worker* please inform me if I can get a satisfactory circulation with a boiler setting in a basement and connected with a range on the floor above, which would make the top of the boiler below the bottom of the range? I have tried every way to find space for the boiler without putting it in the basement, but it is impossible.

Answer.—There would be danger with the arrangement described, for under heavy firing steam would be sure to form in the water back and probably in sufficient quantity to drive all of the water out of a hot water back, and when, through condensation, water could again enter an explosion through quick generation of steam would be a natural result. The boiler may be auspended horizontally from the ceiling in the room where the range is, with the side opening at the bottom to carry the cold water to the water back and the return to connect with the opening in the bottom of the boiler. The supply may be attached to the opening having the tube as usual, and the hot water outlet should have a pipe to run into the boiler and up near the top, ao as to secure the hottest water. A boiler is frequently set in an upper room.

Sheathing for Tin Roofing.

From B. J. P., *New York.*—I intend putting tin on a steep roof, using the standing seams, and a question ariaes with me whether the tin will rust quicker on the under side if the sheathing is laid about 2 inches apart than it would if matched sheathing is used laid tight. I would like to hear from the roofers on this subject.

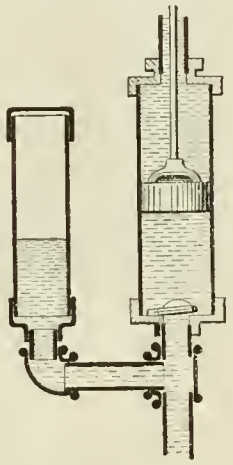
Buoyancy of Air Chambers.

From B. S., *Connecticut.*—I am making air chambers to put in a sail boat which are 10 inches in diameter and 26 inches long, made of galvanized iron of No. 28 gauge. Please inform me what is the buoyancy of these cans—that is, how much will each one hold up in the water?

Answer.—A calculation shows the weight of the cans to be about 5 pounds apiece, or, allowing for the seaming of the metal and the solder, &c., perhaps a little over 5 pounds. The capacity of a can 10 inches in diameter and 26 inches long is 2042 cubic inches. Reducing this to cubic feet and multiplying by 64.08, which is the weight in pounds of a cubic foot of water, we find the weight of a volume of water of the capacity of a can to be 75.7 pounds. Allowing 5.7 pounds for the weight of the can itself gives a buoyancy of 70 pounds each. We have taken no account of the weight of the air, as it would be a very small matter to allow for.

Vacuum Chamber for Drive Well.

From C. S. S., *Litchfield, Minn.*—I send a sketch of a vacuum chamber which I have used with good results in several cases where pumps in drive wells failed to operate properly. Of course the chamber will not make a pump give water where there is none, but it will greatly increase the capacity of any single action pump that is connected with a drive well where there is a supply of water. The chamber will also greatly relieve the pump from the jerk or kick caused by the water not



Vacuum Chamber for Drive Well.

coming up the pipe as fast as the plunger rises in the cylinder. The partial vacuum in the chamber above the water line causes the water to rush through the supply pipe during the upward stroke of the pump handle or downward movement of the plunger. When the handle is forced down and the plunger raised, water is drawn from the chamber as well as from the supply pipe. I have applied this device to pumps in drive wells that worked very hard and gave a limited supply of water. In every instance it overcame the difficulty, and in some cases caused the pump to work as easily as if connected with an open well. I hope this device will be of service to the readers of *The Metal Worker*, and that some of them will give it a trial and report the result.

Strips or Sheet at a Time?

From C. A. W., *Chicago, Ohio.*—I would like to be informed through *The Metal Worker* which makes the best flat seam roof when 20 x 28 tin is used—that laid sheet at a time, or that put on in strips when the strips are from 18 to 26 feet long? What is a "kicker," of which "J. F. S." speaks in *The Metal Worker* of March 31?

Note.—We hope our readers will answer this correspondent on the roofing question. The "kicker" is the name generally applied to roofing seamers made by different manufacturers, and probably comes from the use of the foot in operating them. They are used, in standing seam roof, to turn the higher edge over the lower one, which is done by the hands, while the turn down is closed tight by stamping the foot on a lever.

Lukewarm Water.

From C. D. F., *Berwick, Pa.*—I am called in to arrange a plumbing system, that was erected by another person, so that hot water can be got from it at all times. I inclose herewith a sketch of it. An ordinary range is connected with a 50-gallon boiler, and after it had run for a few days only lukewarm water ran from the faucets. The boiler was connected with the water back with 1-inch pipes. I took these out and put in ¾-inch pipes, and for about eight or ten days a good supply of hot water was secured, when the old trouble was renewed and only lukewarm water could be drawn. I shall be glad to receive any suggestions as to what would overcome this difficulty, for it is the first time I have been stuck in 35 years of practice. There is a good supply or force of water at the top story even when five or six hot water faucets are opened.

Note.—Our correspondent's sketch has not been reproduced, as the method of connecting the boiler showed nothing unusual, and the pipe if run as shown had no defect. We will be glad to have our readers make suggestions as to the cause of the lukewarm water after a supply of hot water has been secured from the system. We think that the changing of the pipe from 1-inch to ¾-inch was a move in the wrong direction, although this would not create the trouble reported. It is possible that the water deposits lime in the pipes and partially closes them, or it might be that the longer the fire is run the more ashes accumulate against the water back and reduce the heating capacity.

Cold Water Comes First.

From W. L. H., *Sudbury, Ont.*—I inclose you a sketch of a job of plumbing which I have done in our town which does not work satisfactorily. The difficulty is hot water cannot be gotten before about a pailful of water is drawn from any of the taps. Three-quarter-inch pipe is used throughout, with the exception of the boiler connections, where 1-inch pipes are used for connecting a 40-gallon boiler with the water back. The hot water pipe is brought up above the supply tank and a check valve put on the end to prevent air entering from the tank and to permit the escape of any air or steam that may arise in the boiler.

Answer.—We have not reproduced our correspondent's sketch, which shows

fixtures on the same floor with the boiler and on two floors above it. It is natural that the water in the pipe between the boiler and the fixtures will become cool if none is drawn off and that when the faucet is opened the cold water in the pipe would have to escape before the hot water comes. This can be overcome by connecting a smaller pipe with the hot water pipe at the highest point and returning it to the boiler and connecting it with the pipe from the boiler to the water back. This will keep up a continual circulation and enable hot water to flow from the faucets as soon as they are opened.

Wants Furnace Suggestions.

From CÆSAR, *Louisville, Ky.*—In the diagram and request from "A Tinner, Montana," in *The Metal Worker* March 24, for suggestions regarding the heating of a church, I notice one omission on his part that is very essential for a person to know before he can intelligently make suggestions: it is the size of the furnace. This church should have a furnace with a 30 to 32 inch fire pot at the least. In regard to the outlet for smoke, "A Tinner" has a very serious difficulty to overcome at the outset in a 10-inch collar and smoke pipe and an 8-inch flue. The smoke pipe has an area of 78 square inches, and the flue has only 64 square inches, making a difference of at least 25 per cent. against him. This, however, can be overcome by constructing a flue box having a 10-inch collar on one end and two 8-inch collars on outlet end. This box should be not less than 18 inches wide and 12 inches deep and 12 to 14 inches long, that is, from collar on furnace to end where both 8 inch pipes connect. Then divide the box by a partition placed perpendicularly so as to throw the two 8-inch collars separate from each other. This partition must continue the full length of box until the end of partition will divide the 10-inch collar on furnace into two equal parts, as shown by sketch. By this construction a workman is enabled to attach from two to four smoke pipes to one flue or *vice versa*. In regard to the registers, it is noticed that the hot air outlet is cramped, being only 685 square inches in area, and the exhaust, as near as can be judged by the size of registers, one 20-inch and two 12 inch, equal 540 square inches in area, making a difference of 145 square inches. In the style of heating adopted in this case the exhaust should equal hot air inlet in area. If I might offer the suggestion I would plant this job as follows: One 48-inch round register over furnace with an area of 900 square inches. I would connect pit under furnace with 18 x 18 registers placed in four corners of church by four 17-inch pipes having a combined area of 907 square inches. This will give a complete circulation in the church. I notice that all of the exhaust is placed in south end of the church, while the north end, which is the coldest end of building, is left to contend against the natural pressure from the north and west, but also against the unequal circulation inside. I hope that these suggestions will be received in the same spirit in which they are offered.

Wants Furnace Suggestions.

Loss of Steam Pressure.

From J. G., *Philadelphia.*—I think, from reading *The Metal Worker*, April 7, that "H. B. C.," St. Louis, probably has gauge pipe on kettles obstructed. I would suggest that he transpose kettle gauge to steam pipe and steam pipe gauge to kettles and note the result. While kettle gauge is off blow steam through opening where it was. Look into gauge and see that it is not obstructed. When sure that gauges are both right—if result is as now—then he has a leaking pipe underground, or steam traps leak through. If the kettles are very large and the contents cold, probably the ¾-inch supply pipes are too small to maintain pressure above 20 pounds. Possibly the valves have the pressure on top of the disk instead of under it, and the disk drifts upon the valve opening, being loose, and partially closes the same. I have known a loose disk to entirely close a line of steam pipe, and while the valve handle turned the disk did not respond, consequently when the valve was thought to be open it was really closed.

From R. D., *New York.*—In reply to "H. B C.," in *The Metal Worker* of April 7, would suggest that he disconnect the kettle and see if the annular opening between the two shells has not been contracted more than was intended, or the steam pipe may go through so far as to come in contact with the inner shell, thereby contracting the opening. It may be that the valve on the trap has been removed and allows the steam to blow through. The gauges may not be placed in a favorable position. I would take out all the ¾-inch pipe, also the gauge pipe, and ream them out, as the cutters leave large burrs projecting on the inside, which is very serious where the pipe is small.

From REX, *Rochester, N. Y.*—If "H. B C.," St. Louis, will turn steam on to his kettles when empty, he will find that the pressure on the kettle gauge will stand very near the same as the gauge on the line; by filling the kettles with water he will see how quick the pressure will drop, showing that the steam connections to the kettles are too small.

Fuel for Furnaces.

In a letter from a correspondent in Rochester, N. Y., entitled "Fuel for Furnaces" and published in *The Metal Worker* of April 7, page 36, appeared some misprints which need correction. In the first column, on the twenty-fourth line from the top "250 bushels" should read "520 bushels," and similarly in the thirty-second line. On the fifty-ninth line the price of coal should read $5.25, and in the fourteenth and fifteenth lines from the bottom of that column the phrase "three times longer" should read "three days longer."

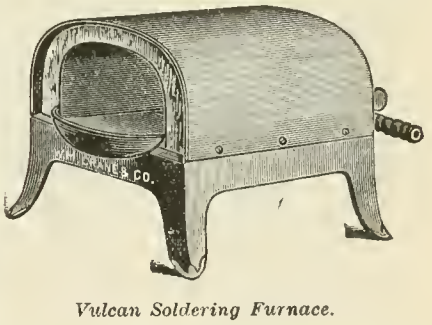
A. B. Sproul, New Haven, Conn., tin and sheet iron worker, has been obliged by increase in business to add to his premises and has taken in 240 Wooster street in addition to 242 Wooster street, where he has been located.

Chicago Builders and Walking Delegates.

The builders and contractors of Chicago have planned a grand *coup* for the discomfiture of the walking delegates who have been giving them so much trouble this spring. It is the cessation of all building operations throughout the city on the 12th inst., to continue until an agreement can be made by the employers and their workmen which will enable work to be prosecuted without the vexatious interference of the walking delegates, who are constantly fomenting trouble in order to magnify their own importance. There is no question of wages involved in this movement, although in some lines there are such disputes pending. These troubles, however, are to be settled by those interests which are directly concerned. The builders, contractors and materialmen have formed an organization styled the Central Building League to carry out their purposes. The action was taken at this time to forestall strikes threatened in several trades which promised to seriously interfere with building operations now becoming unusually heavy. It is deplorable that action of this kind should seem necessary just as workmen are finding employment in large numbers after a most trying winter of scanty work and great privations. The conflict, however, has been brought about by the workmen themselves. It is hoped that a speedy settlement may be made, so that the interruption to work will not be serious. If it should be prolonged it will be a severe shock to business, as so many interests are affected apart from those directly engaged in the unfortunate controversy.

Vulcan Soldering Furnace.

W. M Crane & Co., 838 Broadway, New York, are marketing the Vulcan soldering furnace, as here illustrated.



Vulcan Soldering Furnace.

It is intended for heating soldering coppers by gas. The burners are located on each side of an opening 7 inches long and 2 inches wide in the floor of the oven, and so arranged that melted solder cannot get into it and clog them. Parallel with the floor of the furnace are a set of cast iron supports on each side, on which a pair of coppers can be placed, keeping them warm when not in actual use. When needed, the copper rests directly over the opening, so that the flame passes over and around the whole copper. The furnaces are made in two sizes, Nos. 1 and 2. No. 1 is 8½ inches long, 5 inches wide and 7 inches high, No. 2 being the same length and hight, but 2 inches wider. These are brick lined, to economize fuel. Nos. 3 and 4 are similar, but not lined. The consumption of gas is put at 12 cubic feet an hour, but can be graduated at the cock if less be required.

Press Working of Sheet Metals.—IV.

BY OBERLIN SMITH.

Cutting Processes.

Having more or less accurately formulated the ideas of writer and reader regarding tools and materials, we will now deal with actual processes, showing in such diagrams as may be necessary only conventional forms for shear blades, dies, &c., and omitting as far as possible, for the sake of simplicity, pictures of the presses themselves or of the methods of fastening dies thereto. The details treated of will generally require only certain views of the working surfaces of the respective dies and of the materials worked therein. The letters U and L will represent upper and lower dies respectively in their conventional sense, although it must be remembered that the respective positions of these are, in practice, sometimes reversed, or in some cases turned at right angles or at some other angle to their usual vertical position—as in horizontal shearing machines, inclined presses, &c. The metal or other material when shown between the dies will usually be represented by dotted lines and will be marked M.

Chiseling.

If we analyze cutting processes as performed in presses we find a most primitive idea to be that of the chisel, as shown in Fig. 84. This is in a certain sense a form of coining or forcing the tool bodily into the metal. Practically it is an application of the wedge, which was probably carried out in antediluvian times, when the primeval metalworker found a particularly sharp edged stone and pressed it hard down upon his piece of copper or lead that he might separate it and make the one twain. In modern practice this principle is carried out in the blacksmith's chisel, in the tinman's punch, in various sharp edged dies for cutting shoe soles or other articles of leather, paper, &c., and in that form of foot or power press known as a "sprue cutter," which is usually made with two chisels meeting each other, as in Fig. 85, or more often with one sided chisels, as in Fig. 86, these leaving less of a lump upon the casting *s* when the sprue *c* is removed.

In all chiseling processes there is, of course, a tendency to raise a burr upon each side of the knife, as shown by the dotted lines in M.

Shearing.

The next and most usual process for cutting materials embodies the principle of shearing, shown in its most primitive form in Fig. 87, where a certain part of the material is pushed away from a plane represented by one of its surfaces, as *a a*, Fig. 87, into another plane parallel thereto, by being slid past the other part of the material, which remains in its normal position. This sliding of certain particles or molecules of metal past certain other ones constitutes the stress known in engineering by the general term of "shear," and is governed by well-known laws as to the resistance of the material itself. These laws it is not necessary now to define or formulate further than the reference which will be found near the end of this chapter to the pressures required for such shearing.

In Fig. 88 is shown, in end view, a more usual form of shear blades, the cutting edges being made at an angle of about 75° between their two limiting surfaces, instead of 90° as in Fig. 87. In Fig. 89 is shown the same blades as they often appear after practical use, with their edges rounded off and their adjustment altered so that their vertical faces do not touch one another. In Fig. 90 is shown the appearance of a bar of metal as sheared apart at *s* with the dull blades just mentioned. In the left hand piece the lower corner is rounded, while the upper corner runs up into a sharp burr that has crept up between the blades. Just to the left is an indentation caused by the compressive action of the blade itself. The other piece of metal is, of course, the same but reversed in position.

In Fig. 91 is shown in vertical cross section a piece of sheared sheet metal with the same rounded corner and the same burr at the top, but with a cleaner cut, as made by sharper and well set blades. The burr and round corner are exaggerated, but they are usually present in some degree in all kinds of shearing and punching work. They must be allowed for even in working thin metals with sharp dies, as it is often a matter of consequence on which side of the work this slight burr shall appear and which side shall have a slightly rounded corner.

In Fig. 92 is shown a face view of the blades in Fig. 88, the same being made parallel, so that all points along their cutting edges will come into contact with the metal at the same time. This form is best where the metal must not be twisted or otherwise disturbed, and is good enough in any case where it is quite narrow in comparison with its thickness, as with square bars. With such proportions it obviously is not practicable to much lessen the pressure required to do the cutting by dividing it up and extending it over a longer time. Such an extension of time and lessening of the pressure at any particular moment may sometimes be obtained, however, by making one of the blades, like the upper blade in Fig. 93, with an inclination of the edge, commonly known as "shear." This evidently is useful only where the width of metal cut is considerable. It is obvious that in such case one edge of the piece of bar or sheet metal is pushed down by the upper blade and depressed in advance of the other edge, thus producing a bending action across the sheet which distorts it more or less from its original flat condition as at M. This action is seen in the curling up and twisting of a narrow strip cut from a piece of paper with a pair of scissors, or a sheet of tin plate with a pair of snip shears. In many cases it does no harm, and we therefore see the great majority of shearing machinery made in this way. This inclination of one blade to the other is usually somewhere between 2° and 10°. If the angle is too great the tendency of the work is, obviously, to slide lengthwise of the blades, or toward the left in Fig. 93. The greater the angle the easier the work is done by the machine and the more the sheet is distorted, and *vice versa*.

It is very desirable that the word "shear," as designating the angle of inclination referred to and also the act of mechanically producing such inclination, should be changed for a less confusing term, as this word is already used in many cases for the press itself which does the shearing and for each of the blades which are mounted thereupon, and for the act of doing the cutting work itself. Thus in this connection we may easily have such an awkward and misleading sentence as the following:

"Tom, shear half an inch the upper shear in the two-ton shear, that it may shear more easily by having more shear—and, I say, Tom, leave a sheer opening of an inch and a half."

The above sentence reads like sheer nonsense. It is, of course, given as an extreme case of the evil referred to, but I have heard orders uttered which were nearly as confusing. The word in question is above used the first time as a verb, denoting the act of grinding more inclination upon one of the blades; the second time as a noun, meaning the blade itself; the third time as a noun, meaning the machine in which the blades are mounted; the fourth time as a verb, denoting the act by the machine of shearing the material worked upon; the fifth time as a noun, designating a detail of construction of the blades, and the sixth time (differently spelled) as an adjective, defining the space between said blades. In my own practice I am endeavoring to use the term "dip" as a substitute for "shear" in this connection, but I probably may not succeed in inducing the public to accept it. This word is given by Webster as a synonym for slope and pitch and has in its favor brevity and crispness, together with no danger of confusion with other terms apt to be used in the same connection. It also is correct from an engineering point of view (at any rate in the case of ordinary upright shearing presses) as representing some angle of inclination with the horizon, and it is already applied to such angles in mining parlance when speaking of mineral veins. It would also seem somewhat appropriate in speaking of gangs and punches as shown in Fig. 97, which are set with their lower ends in a series of different hights, that they may not enter the work all at once and thus bring the pressure required for each cumulatively upon the press. In this case certain of the punches have a dip, so to speak, below the other ones, in the sense of reaching downward. A word often used in connection with such punches is lead, meaning that one has the lead of some other one in first striking the work. To tools of this kind the word "shear" is hardly applicable at all, but the word "dip," if it could be generally introduced, would answer for all cases of punches as well as shear blades.

Punching.

In Fig. 94 is shown in vertical axial section (which, by the way, is the kind of view given in most of the previous pictures where circular work has been represented, and which will be usually understood hereafter unless otherwise specified) a pair of ordinary round cutting dies, without dip, both working surfaces lying in planes parallel to each other. It is evident that such a pair of dies are in principle simply a pair of shear blades, like Fig. 92, bent around into a circle, and that the same principles involved in ordinary shearing hold good. This statement may be somewhat modified where the diameter of the blank (this term "blank" meaning in general any shaped flat piece cut from a sheet) is quite small in comparison with its thickness, as for instance in

[*Correction.*—In the article on "Press Working of Sheet Metals" in *The Metal Worker* of March 17, page 45, Figs. 76 and 77 were transposed, the latter being intended to represent the end of a flat bar of metal and the former a sheet of tin plate. Upon page 47, in the thirty-first line from the top of the first column, Fig. 82 should read Fig. 81.]

punching boiler plate, &c. In such cases a little more force must be required to do the shearing, on account of the blank being tightly confined in the hole from which it is pushed; while in doing the same amount of shearing in a straight line the piece cut off usually falls freely away without friction.

In Fig. 95 is shown an upper die or punch, such as is often used for boiler work, &c., with its lower end made in a spiral form, instead of lying in a plane normal to its axis. Various experiments with such punches have shown them to require considerably less force to drive them through than in the case of the ordinary flat bottomed ones.

about the vertical axis of the ram. Of course this cannot always be done, and in such cases a more rigid press will be required than in the other case. The lower die L in Fig. 96 is also shown dipped, having in this case four high points. In practice, however, one die is usually made flat, all of the dip being put upon the other. Which die should be flat depends upon the nature of the work. With a thin material, such as tin plate, and with diameters, say, not over 2 inches, this point is of little consequence, as both the blank and the sheet outside of it, if sprung out of flat while the die is going through, will readily be restored to a flat condition

In general, it is better theoretically to have only two high points upon cutting dies, either round or otherwise, as the metal which is sprung out of flat by reason of the dip is, in such case, simply bent into an approximately cylindrical shape, while with more than two points it is distorted in more than one direction into a dished shape or otherwise, which may permanently warp it beyond power of recovery, because certain parts of the metal are then actually stretched while others remain normal. This can be vividly demonstrated by merely bending a thick sheet of writing paper, which does not hurt it, and then by pushing it a little way into one's hat,

PRESS WORKING OF SHEET METALS.

In Fig. 96 the same principle of dip is shown in the upper die U with its two high points *d d'*. These strike the metal first, the bottom of this die being scooped out in general as if it had been held against a cylindrical grindstone. For large diameters this is much better than a single high point, as in Fig. 95, because the pressure upon the press ram is balanced, whereas with one point striking the metal first there is a tipping action which tends to spring the ram and upper part of the press frame out of a vertical position, and consequently to slide the upper die sidewise over the lower one. Such action often occurs in practice, to the considerable detriment of the cutting edges, and great care should always be taken, where a die is over 2 or 3 inches in diameter at any rate, to see that it strikes the metal at two or more points equally balanced

by their own elasticity. If, however, the metal is thick and rather non-elastic and the diameter small, it is evident that an upper die scooped out, as in Fig. 96, would bend the blank, perhaps beyond its elastic limit. In such cases, therefore, the upper die should be perfectly flat, that is, if no damage will be done to the sheet outside by its being bent as it rests on the dipped lower die. Usually in such cases this sheet outside is only scrap, and such bending will make no difference. If, however, it too must remain flat, the only recourse is to make both dies without dip and use more pressure to drive them. In cases where mere perforating is done—that is, where the sheet outside the blank is the article required for use and the blank is regarded as scrap—the upper die should always be the dipped one.

which ruins it. Practically, with thin metals this action may be neglected, and it is often best to put a high point at each angle of the contour line of blank, as *e. g.*, three in a triangular die, four in a square one, &c. These points entering the other die first serve to guide their relative motion during the rest of the stroke and thus to protect such parts of the cutting edges as follow after in their contact.

In Fig. 98 is shown a part of the frame of a press with a pair of plain shear blades mounted directly upon bed and ram. In Fig. 99 is a similar view, with shear blades made for cutting off round iron, there being a series of semicircular notches in each blade adapted to the sizes of iron to be worked. Upon this view there is also shown an adjustable gauge, G, such as is often used for pushing a bar against,

to regulate the length of the piece cut off. In Fig. 100 is a similar view of a deep throated press frame, with a small round punch and die mounted in chucks set therein, and supplied with an adjustable stripper, S. It may be here remarked that the word "punch" is very generally used to designate an upper die, whether cutting, forming, drawing or otherwise, but this practice is not universal. In many cases "upper die" is the better term—for one reason, because the word "punch" is also used as a verb to denote the operation and as a noun to designate the press itself, which is often called a "punch," especially if used for small holes in thick metals. The three views just given are copied from various machines commercially in the market, but are not given as of ideally the best design.

Blanks.

In Figs. 101 to 133, 135 to 150 and 155 to 160, all inclusive, are shown top views of various blanks, each of which has been cut from the sheet at one stroke of an ordinary pair of cutting dies. They are mostly of such shapes as are produced in ordinary tinware factories and consist chiefly of parts of pots, kettles and pans, &c. Figs. 151 to 154 have been merely sheared apart from a rectangular sheet by a gang of curved shear blades, thus producing at one blow the necessary pieces for a stove pipe elbow. Such work as Figs. 134 and 161 are perforated in gang dies, where a number of punches are set in an upper plate, as shown in Fig. 97, and where the lower die usually, but not always, consists of a single plate of steel containing proper holes for the punches to enter.

Gang Punching.

Fig. 162 illustrates a system of gang punching used for producing washers like Fig. 164 and other perforated articles. A pair of dies for such work are shown in Fig. 165, where the metal M, being fed in the direction of the arrow, is advanced to the point *a* at first stroke of the press so that the punch *u* will perforate it and drop through the punching or blank M′ (or Fig. 163). It is then advanced to the point *b* so that at the second stroke the punch *u′* will make the large hole around the small one. The pintle P, projecting below the same and set centrally therewith, enters the small hole and serves to guide the metal more accurately than would otherwise be done by ordinary gauging, so that a completed washer M″ (or Fig. 164) drops through the lower die L. At the same time the punch *u* is punching a second hole and dropping through another blank M′, which again is advanced at the next stroke to have another washer punched from around it, &c. Thus is produced a complete piece of work at each stroke, except the first and last at the respective ends of the bar or sheet. This method can of course be amplified so as to punch any number of holes, of any shape, and in any relative position, at the first stroke, and then, at subsequent strokes, to punch around each one separately or around or between any of them or any groups of them that may be desired. In this way are cheaply produced many small articles such as keys, parts of locks, &c.

Combination Cutting Dies.

Another general method of producing completed pieces at a single operation is by combination cutting dies, wherein one or more male dies are usually set inside of a female die, and *vice versa*. The sexual terms just used have not been before mentioned herein, but are generally understood as designating respectively any punch, such as U, Fig. 94—the male—which enters a die, and any die, such as L—the female—which is entered by a punch. This nomenclature applies not only to cutting dies, but also to those for forming, drawing, &c.

In Fig. 166 is shown a typical form of combination die of the kind referred to, which will produce any perforated work like Figs. 134, 161 or 164. As shown, it is arranged for cutting simply a circular ring or washer, M. Such ring, of course, remains upon top of the lower die L, the small blank cut from it dropping through as usual. An inspection of the picture will show that L consists of a male die at the outside and a female die in the center, while U consists of a female die outside and a male die in the center. The rings K K′ are used as knockouts or strippers and are usually driven by springs, the function of K being to drive the finished ring out of the upper die and of K′ to lift the surrounding remainder of the sheet from the lower die. The work is, of course, shoved out sidewise or backward, either by means of the sheet itself or by means of gravity, when the press happens to be in an inclined position. Such dies as these are largely used for cutting armature disks and such like accurate work, oftentimes being built with a large number of teeth or notches around the outer edge, which obviously makes them very expensive. They are, however, usually built up in sections, so that if one piece needs repairing or renewing the whole die need not be thrown away. Sometimes dies of the kind just described are turned upside down from the position shown. The objection to this, however, is that the blanks from the perforations have to be driven upward through a hole or tube which usually curves over and delivers them at one side of the upper die, or of the ram, should they be pushed so far up.

Recurring to ordinary gang punching dies for producing work, or rather scrap, of the general character shown in Figs. 161, 167 and 169, it is evident that in some cases the holes might be so near together that the little isthmuses, as we may call them, *i*, *i*, *i*, &c., would be too narrow (so as to avoid waste of metal) in the female die to secure the requisite strength for it to hold together. The remedy in such case is to so set the gang of punches and corresponding holes in the lower die that certain alternating holes may be punched in the metal, omitting the ones between, as for instance in Fig. 167, where those marked A are thus punched first. This diagram represents a sheet of tin plate from which six fruit can tops have been made in gang combination dies. The lower die is shown in top view in Fig. 168. After the first stroke the sheet is either turned around or turned over so that at the second stroke all those holes marked B will be punched, and so on. In feeding a long strip of metal by this system (see Fig. 169) there is no lost time except at the ends of the strip, where, for instance, in the case shown, only two holes, A A, could be punched at the first stroke, two whole ones and three halves, B B, &c., at the second stroke, but the five complete ones, C C, &c., as located in the lower die, Fig. 170, at the third and subsequent strokes.

A great deal of work is done upon this system in brass factories and other places producing small articles from long rolls of metal, the feeding usually being automatic. I am informed that this principle of interspacing dies has recently become the subject of a patent which, of course, is an absurdity, as the system is very old.

Cutting Dies.

In general, some of the important points desirable to secure in cutting dies are first rate material of proper hardness; great rigidity against distortion by springiness, especially in lateral directions, and durability by having ample length of bearing surfaces, as from *w* to *x* and *y* to *z*, in Fig. 94. Each die between these points should be perfectly parallel, so that when sharpened by grinding off the top surface of L and the bottom surface of U they will still fit each other as tightly as at first, or as nearly so as is consistent with what their cylindrical or prismatic surfaces, as the case may be, which slide against each other, have actually worn away. It is, therefore, very bad practice to make the hole in a round lower die conical all the way through and to make the upper die conical, decreasing from the bottom upward. Such dies will work well at first, but have very little life, whereas if made as in Fig. 94 they can be ground away gradually (upon their horizontal surfaces) to the points *w* and *z*. Below *z* it is necessary to have the size of the hole somewhat increased to give clearance to the blank, that it may not clog therein. Sometimes this is made conical, as shown, and sometimes it is enlarged bodily and left parallel, with a small step at *z*. It is well, however, to have this clearance quite small. On ordinary dies about 2 inches thick the writer has found it good practice to make the clearance distance *a* from $\frac{1}{32}$ to $\frac{1}{16}$ inch. In the upper die there is no need of giving any clearance, and some die makers even go so far as to make U slightly larger at the top, so that as the lower surface is ground off the bottom diameter is slightly increased, thus maintaining a tighter fit in the lower die than would otherwise be the case. It is generally easier, however, to make the sides parallel all the way up.

Hardness of Dies.

While in the case of punching and shearing thick metals the upper and lower dies or shear blades, as the case may be, are both made hard, there is a large variety of work where one of the dies is made moderately soft, the other one being as hard as possible consistently with not having the sharp edges crack off in working. Such dies can usually be worked upon all metals no harder than iron or very mild steel which are less than $\frac{1}{16}$ inch thick. The object is that the dies may be quickly and cheaply repaired, as far as maintaining sharp cutting edges is concerned, by hammering up the top or bottom surface, as the case may be, of the soft die, thus spreading out or riveting such die sidewise, making it larger if it be the male and smaller if it be the female. This can often be done without unsetting either of them from the press. After the proper amount of hammering the dies are oiled and forced together, the hard one shaving or broaching off the surplus metal from the soft one, thus leaving them again a good fit, one within the other. It is, of course, necessary that the hard die should in such case have a reasonably sharp edge. In most cases it is best to have it freshly ground.

The vexed question of which die shall be hard, male or female, is not of very much consequence, although many peo-

ple take it for granted that it should be the female, simply because they have always been accustomed to that method. One good reason exists for this, however, viz., the presence of a hard surface, which will not wear away so fast, over which to slide the sheets, these sometimes being covered with scale, and therefore doing a good deal of grinding on their own account. In some cases, however, where great accuracy of shape and size is required it is difficult to make the female die hard, because of the trouble of grinding it out to exact dimensions after hardening, ordinary grinding machinery not being made for sliding through small holes of irregular shapes. If, on the other hand, the male die is hard it usually can be ground exactly as wanted, because such grinding is on the outside where accessible. The reason for such after grinding being necessary is, of course, the warping or shrinking, or both, of the steel, which often happens after hardening to an extent great enough to spoil the accuracy with which the die was originally made. The difficulty of grinding above spoken of obviously does not occur with round and elliptical dies, as the female ones can be ground out inside in ordinary grinding lathes.

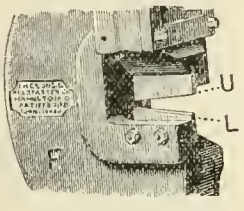

Fig. 98.

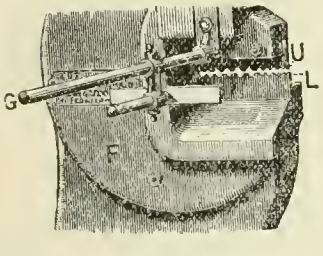

Fig. 99.

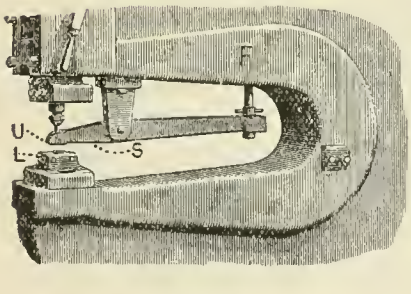

Fig. 100.

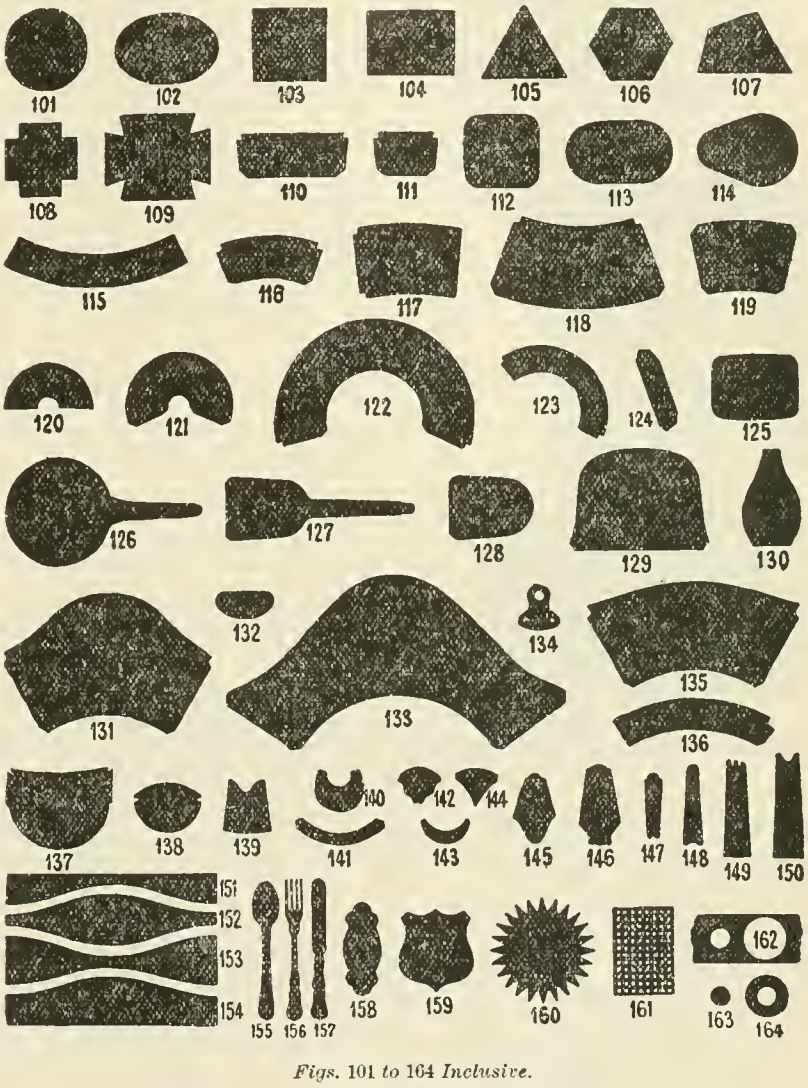

Figs. 101 *to* 104 *Inclusive.*

Bevels of Shear Blades.

The bevel of shear blades has been already referred to as being usually about 75°. This angle of course appears in cutting dies, as A and A′, Fig. 94. Its object is chiefly to facilitate the grinding and hammering up practiced in repairs, although it is supposed that the metal is cut easier, with a little less power, than when the edges are at an angle of 90°, as in Fig. 87. Just how much power is saved thereby I have at present no accurate data regarding. In some cases, however, it is better to make the surface of dies perfectly flat, with a 90° angle, to avoid the little notch that is left in the work, as shown at *n n*, Fig. 90.

Strippers.

It is usually necessary to supply a male cutting die with a stripper, which in general consists of a stationary ring surrounding it and extending slightly below it when in upper position, as shown at S, Fig. 96. This is usually secured either to the press frame back of the ram or to the lower die or bolster, it being bent downwardly in such case to meet the place of fastening. The latter method serves a good purpose where the downwardly extending portion is not in the way of the sheet, as for instance where the sheets are narrow. If, however, it is desirable to move the sheet back a considerable distance, as for cutting another row of holes forward of the first row, &c., a stripper is apt to be in the way if mounted as last mentioned. Sometimes a stripper is a ring sliding upon the male die and driven down by springs abutting thereagainst. In still other cases it slides in this way, but is struck upon the up stroke by stationary abutments fastened to the press frame.

Gauges.

In regard to gauges, they are too numerous in design to be described in detail here. In their simplest form they are simply round pins, projecting from the upper die, as at G G′, Fig. 96, for back gauges and G″ for an end gauge, so called. Sometimes, however, gauges are so arranged as to confine a strip of metal at both front and back, and in many cases the end gauge G is arranged as a finger gauge, so that it will move up and down automatically by the action of the press at the proper time. When the feeding and gauging is done by hand, however, the work is lifted so as to slide over the top of G″.

Speed of Dies.

In regard to the best speed for running cutting dies, but little has been accurately determined. The ordinary quick running presses in common use, making from 50 to 150 strokes per minute and generally averaging perhaps 100, seem to work well for shearing and punching most of the common metals which are not over ¼ inch thick. An exception, however, should be made for cast steel, for cutting which a press should be geared so as to run very much

PRESS WORKING OF SHEET METALS.

slower than for mild steel, iron, brass and the softer metals. The reason for this is simply to get more durability in the dies, as the edges seem to get dull very rapidly at quick speeds. For punching metals over ¼ inch thick it is usually better to use what is known as a geared press, which generally makes from 25 to 75 strokes per minute. In the cases mentioned presses of short stroke, usually 2 inches or less, are referred to. Where a press happens to have a much longer stroke, it is of course necessary to run at a lower number of strokes per minute to secure the same actual cutting speed.

PRESS WORKING OF SHEET METALS.

Pressures.

In regard to pressure required for shearing and punching, it may be said in general that the actual force required to shear a given unit of section is slightly less than that required to pull apart the same section by stretching—that is to say, in most of the ordinary ductile metals, such as steel, iron, brass, copper, &c. In other words, the ultimate shearing strength of these metals is a little less than their ultimate tensile strength, sometimes (as observed with certain steels) being only about 75 per cent. thereof.

This is assuming sharp cutting edges, however, which are not always present. Considering the fact that such dies are often dull, a safe general rule in providing a press for doing certain shearing or punching work would be to have it capable of safely exerting and resisting a force powerful enough to tear apart 1 square inch of section of the particular metal to be used for each square inch which is required to be sheared. In the case of mild steel this may be considered roughly as about 60,000 pounds per square inch; with wrought iron 50,000 pounds, and with other metals less, but always in the same way, according to their tensile strength, which may generally be found in any engineering reference book—that is to say, in cases where the author of the book has taken the trouble to mention the particular metal which the reader happens to want, which is not always.

To give an example: Supposing a press user wishes to shear off bars of iron 1 inch square, or bars 2 inches by ⅓ inch, or 4 inches by ¼ inch, or to punch a hole 1 inch in diameter (which is about 3 inches round) in iron ⅛ inch thick, or 2 inches diameter in a sheet ¼ inch thick, or 12 inches diameter in a sheet $\frac{1}{32}$ inch thick. In any of these cases he will wish to cut an actual section of about 1 inch square. He will, therefore, need to use a machine which will give 50,000 pounds pressure at the beginning of the cutting operation, or, more accurately speaking, a little after its beginning, when some slight crush-

ing of the metal has taken place. This initial pressure, for instance in the case of cutting off a bar 1 inch square, will not have to be maintained during the whole 1 inch of ram descent while the cutting is going on. This is because the resistance will soon begin to decrease, probably after the first $\frac{3}{8}$ inch or $\frac{1}{2}$ inch of descending, ceasing entirely after about $\frac{3}{4}$ inch of motion, as at this time the bar will have been so disintegrated as to fall apart before being pushed entirely down to the amount of its own thickness.

The maximum pressure necessary, therefore, for shearing proper is measured by the amount of cross section to be cut, and may be formulated thus: Taking P=pressure in pounds required from ram, W=width and T=thickness in inches of bar to be sheared off, and S=shearing strength per square inch in pounds of the material of the bar, we have: WT=area of section cut and SWT=total initial pressure.

Hence P=SWT, that is, providing there is no dip to the blades.

Applying this rule to punching, we let W=circumference, or length of contour line, of the hole, which is really the width to be sheared. For round holes, taking D=diameter in inches, we have W=Dπ (or 3.14 times D). For square holes, taking D'=short diameter, we have W=4D'. As before stated, a rule easily remembered and one that is on the safe side is to let S=50,000 for iron and tin plate.

The rule just given must, of course, be modified in favor of less pressure requirement wherever it is practicable to use dip upon one of the blades or dies. Figs. 171, 172 and 173 show successive stages of the descent of an upper blade, U, upon a bar of metal, M. In the first position it will be seen that the practical width of cut W is only about one-half that of the bar, while in the second it has become equal to the whole width of bar, and this is evidently the maximum width upon which it will act. The average thickness, however, in this position is but one-half that of the bar, and the area of metal yet to be cut is measured by the triangle just below the blade, which is evidently but one-half the area of the bar's cross section. In the last position the width of cut has been reduced. From these diagrams it will be seen that a blade that has as much dip as that shown will require only about one-half the pressure required by a blade without dip, and this is nearly correct, except that some excess would be required to bend and twist the bar, as in Fig. 93. In Fig. 174 is shown a bar twice as thick as before, and it is here evident that when the width of cut has reached that of the bar itself there remains about three-quarters of the area yet to be cut. Consequently the pressure is reduced by the dip something less than one-quarter only. In Fig. 175 is shown the opposite extreme, where only about one-half the width of the bar and one-half the thickness are at the same time being contributed as factors to the area being sheared. Consequently the pressure required is only a little more than one quarter of what it would be with a dipless blade. In Fig. 176 is shown a gang of punches, *a*, *b*, *c*, *d*, *a* having just reached through the bar of metal M when *b* is ready to commence. In the same way *b* will reach through when *c* commences, &c. Thus it is obvious that the pressure required at any time is only that due to the resistance of one punch, but that the whole hight traveled by the ram while doing its work is represented by *h*, which is four times the thickness of M, or, in general, as many times its thickness as there are punches, providing they are set with this amount of dip. An analysis of the preceding diagrams will show that the same rule holds good—viz, that the maximum pressure required is approximately in inverse proportion to the working distance traveled by the ram.

In estimating, therefore, the necessary pressure for any given pair of dies, the pressure required for flat dies without dip should first be ascertained by the formula given above, and then a reduction should be made in proportion to the increase of time during which the dies are doing their work over that due to the thickness of the metal itself, as caused by the particular amount of dip that may be present in the dies.

The pressure data given assume an upper die or punch of the same diameter as the die which it enters, such construction insuring a parallel hole through the metal. This close fitting is usually practiced with metals below $\frac{1}{16}$ inch thick, such as tin plate, &c., but is absolutely necessary with very thin metallic sheets and with soft substances, like cloth, leather, paper, &c. Indeed, a rule frequently used by the writer for accurately testing such dies has been to make them cut wet tissue paper cleanly all around. With thick metals, however, as in boiler making, bridge work, &c., it is customary to make the punch considerably smaller than the die. In some extreme cases this has been as much as one-fifth of the thickness of the metal, which has been proved by certain interesting experiments tried by the Messrs. Sellers some years ago to be a proportion that requires the minimum pressure. Practically, the amount of clearance between punch and die is usually less than this, varying generally from $\frac{1}{32}$ inch to $\frac{1}{16}$ inch in metals not over $\frac{1}{4}$ inch thick. With such clearance the pressure is considerably lessened, but the holes are of course conical. In some cases this may happen to be an advantage, as when the large end can be turned outward in riveted joints, &c., but in other cases it is a detriment.

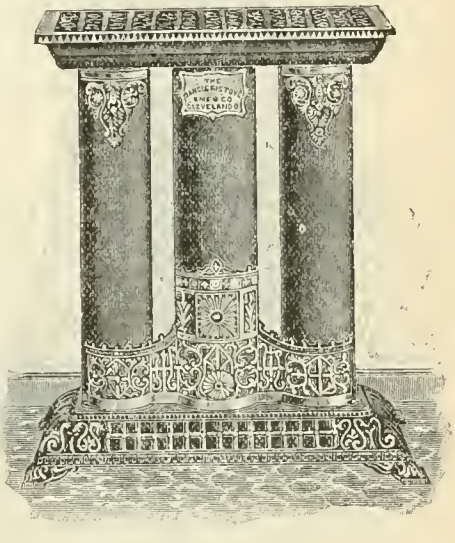
The punching pressure required when holes are located very near the edge of a sheet is somewhat lessened on account of the spreading of the metals sidewise, but this does not amount to much in practice, and such punching should be avoided.

Regarding the pressure required for stripping metal from a punch during its ascending stroke, I have no reliable data at hand. It varies considerably with the amount of punch and die clearance, the smoothness of the punch and the squareness of the stripper therewith, together with its rigidity, &c. It is undoubtedly a good deal less than one-tenth of the punching pressure, even in extreme cases. A series of experiments in this direction are certainly very desirable, and the writer hopes upon some future occasion to be able to publish an experience of this kind which he has not yet enjoyed.

Regarding the kinds of presses used for the cutting processes which have been described in this chapter, it may be said that, like the Scotchman's whisky, there are no bad kinds. In other words, almost any sort of a press is sometimes suitable—the nearest approach to an exception to this statement being perhaps the drop press tribe, whose members are generally employed in other work.

The Dangler Hot Air Radiator.

In the accompanying illustration we present a general view of a hot air radiator which has recently been placed upon the market by the Dangler Stove & Mfg. Company, Cleveland, Ohio, and for which a patent was granted last month. The radiator is referred to by the manufacturers as being new in principle, conveying its heat upward through the center flue, passing it down the two side ones, and discharging it through the openings in the base. The air by this arrangement is crowded into the top of the radiator, causing the flues to become very hot, and while radiating a great deal of heat from the top and sides, it forces the air downward to the openings in the base, enabling persons to warm their feet as readily as by means of a base burning



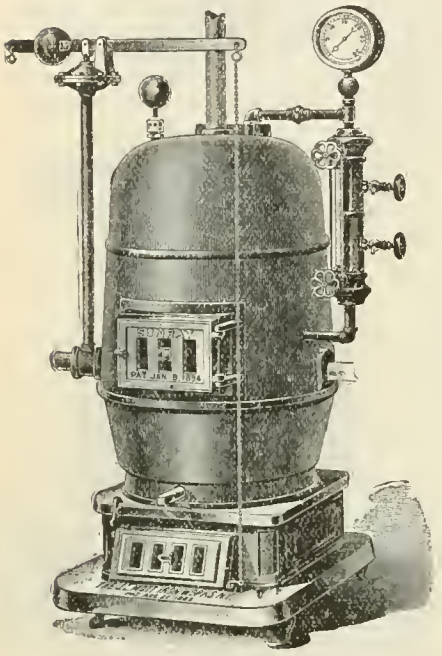
Dangler Hot Air Radiator.

parlor stove. The burner in this radiator is placed at the bottom of the center flue, which, it will be noticed, is a trifle shorter than the ones at the right and left, and is also made a trifle larger in cross section so as to be able to carry a supply of air sufficient for the other tubes. The burner frame is formed with a tubular ring having jets at intervals, and connected at its center by cross tubes and with the gas supply pipe, which passes up centrally through the base, serving as a support for the frame. By means of the construction employed there is a free circulation of air from beneath, both within and without the burner ring. The manufacturers refer to the fact that the distance which the air is forced to travel from the time it enters the central tube until it is discharged through the openings in the base is sufficient to retard the flow just enough to insure good radiation. The arrangement is also such as to render the heat easily controlled, allowing it to be distributed fast or slow, as may be desired. The grating shown at the bottom of the radiator can be easily removed for the purpose of dusting. The appearance of the device is neat, some of the parts being treated with nickel, which forms a pleasing contrast with the black iron surfaces. The radiator shown herewith has three tubes, while other sizes have four, six, eight and twelve tubes. The manufacturers state that this radiator has proven very popular with the trade, and that during the past winter and fall they sold large numbers.

STEAM AND HOT WATER.

The Sunray Steam Boiler.

The accompanying cuts illustrate a new steam heater just placed on the market by the J. L. Mott Iron Works,



Sunray Steam Boiler.—Fig. 1.—Showing Complete Apparatus.

New York and Chicago. The heater is designed for small residence work and for furnishing steam for coffee rooms, steam kettles, carving tables or any

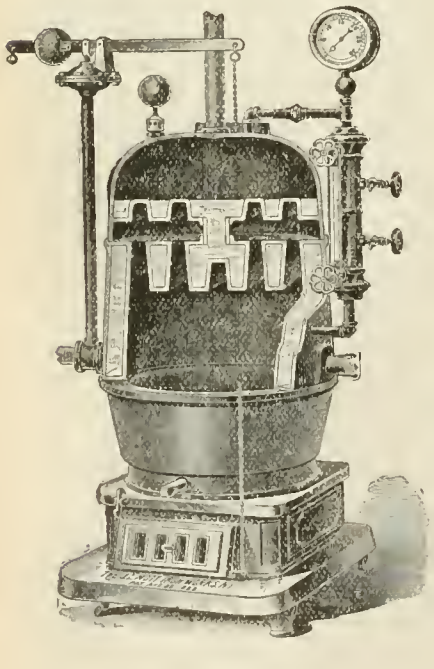


Fig. 2.—Sectional View.

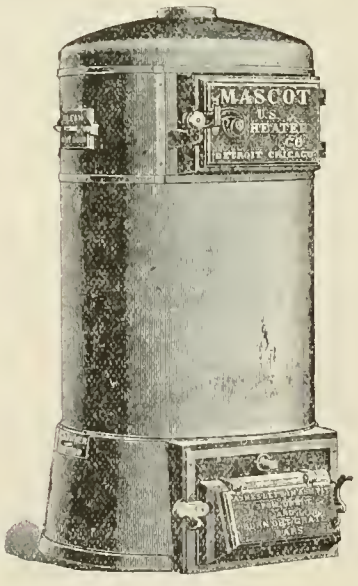
other purpose requiring a moderate supply of steam at a low pressure. It is claimed that technical tests of this heater show a very high rate of economy and efficiency. It has an ample fire chamber and the heating surface is brought in direct contact with the fire, thus making a quick and powerful steamer. Fig. 1 gives the external appearance of the heater, and Fig. 2 is a sectional cut showing arrangement of fire surfaces, water line and steam chamber. It will be seen from the illustrations that no steam or water joints are left for the fitter to make, as the generating part of the heater is all put together before shipment; also that no packed or washer joints are used in its construction. It is easily handled and can be taken in at any ordinary door or window. It is claimed by the makers that this heater can be set up ready for piping in one-half hour after it has been unloaded at the building. This heater is made in five sizes, with grates 14, 17 and 21 inches in diameter, and is capable of supplying from 150 to 400 square feet of heating surface, or the equivalent in any other service it may be used for.

The Mascot Heater.

We show in the accompanying illustrations views of a new heater, known as the Mascot, that is brought out by the United States Heater Company, Detroit, Mich., with Chicago branch at



The Mascot Heater.—Fig. 1.—General View of Mascot Hot Water Heater.

100 Lake street, and New England selling agents Gilchrist & Taylor, 106 High street, Boston, Mass. The heater shown in the illustrations is intended for both steam and hot water. Fig. 1 is an exterior view of the hot water heater, while Fig. 2 is a broken view of the steam heater. The constructions are essentially the same, but the upper chamber in the steam heater is larger. The water space is inclosed between a double shell, the inner surface, as shown in Fig. 2, being corrugated, giving an extended surface and increasing the efficiency of the apparatus. In the hot water heater the steam dome is replaced by a top header or distributing chamber. It is mentioned that the Mascot is so arranged that ample heating surface is presented, while the products of combustion are made to strike first the top

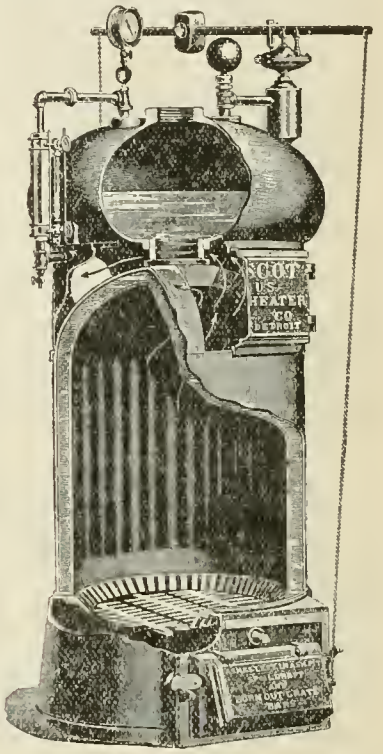


Fig. 2.—Broken View of Mascot Steam Heater.

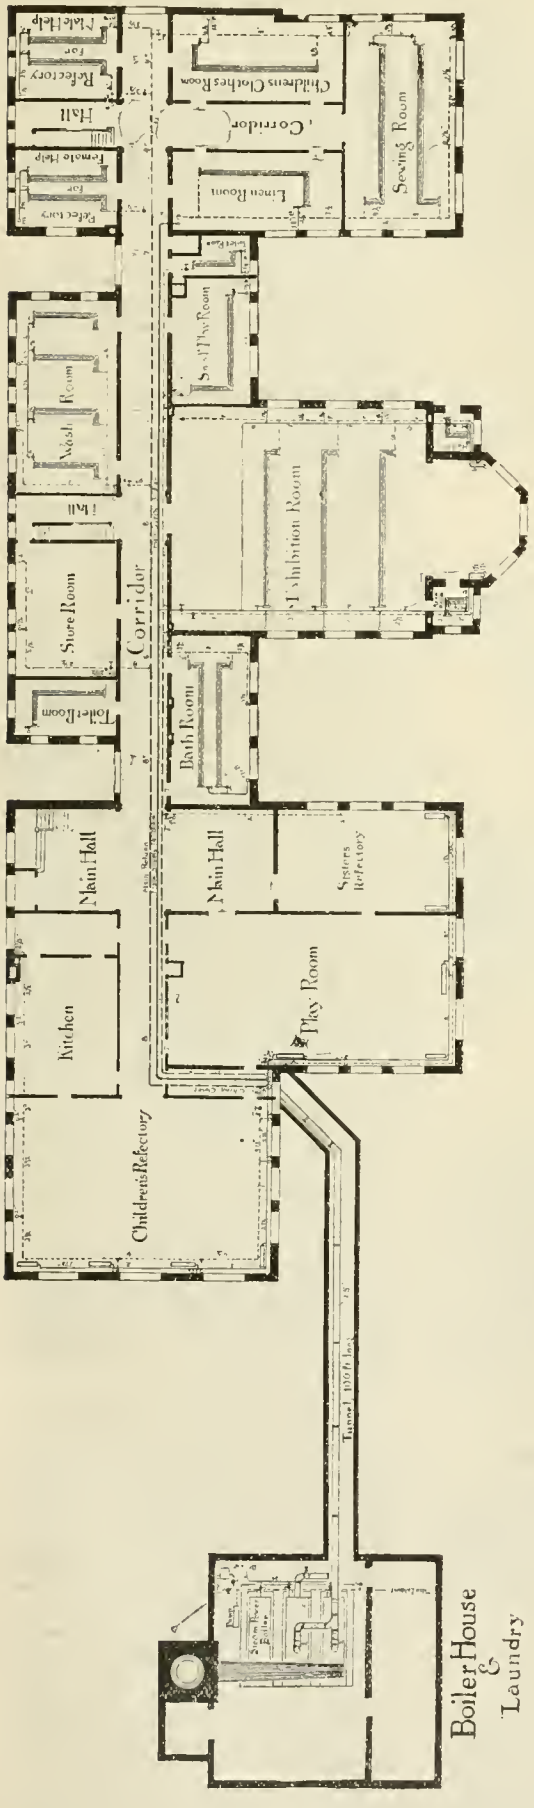
of the heater proper, then the top header or steam dome before finding an exit through the smoke pipe. A special feature to which attention is directed is the ease with which it may be cleaned. It is also easy to handle and set up. The Mascot hot water heater is made in three sizes with diameter of grate 15, 18 and 21 inches, adapted to supply from 275 to 475 square feet of radiation in addition to mains. The Mascot steam heater likewise is made in three sizes with the same diameters of grate, adapted to supply from 175 to 350 square feet of radiation in addition to mains.

THE HOWARD THERMOSTAT COMPANY of Syracuse, N. Y., with New York office at 210 Water street, have brought out an improvement on their thermostat regulator, by which the check of the fire in the furnace is accomplished through the ash pit, thereby avoiding, it is said, any possibility of gas escaping, and affording a quick and efficient check to the fire without admitting cold air into the smoke pipe. They also have in process of manufacture a larger cylinder designed to furnish sufficient check for the largest furnace or heating apparatus constructed. This method of regulating is adapted to hot air, hot water or steam heating apparatus.

An Extensive Hot Water Plant.

The Ringen Stove Company, St. Louis, Mo., have recently completed an extensive heating contract in the St. Joseph's Orphan Asylum at St. Louis. There is a total of 19,500 square feet of hot water radiation, in addition to the mains, which are all exposed and utilized as heating surfaces. The radiation is supplied from two multitubular boilers, 18 x 60 inches in size, with 72 4-inch flues in each. The location of the boiler is shown in Fig. 1, which is a basement plan. Attached to the boilers is a Hawley down draft smokeless furnace, guaranteed by the manufacturers to effect a saving of 25 per cent in fuel. The boiler house is situated 102 feet west of main building. The boilers are connected so that either or both can be used for the purpose of firing heavy or light, according to the weather. The flow and return from each boiler are 12 inches in diameter. The two 12-inch supplies connect into one 15-inch main trunk supply, and the two 12-inch returns into one 15-inch main trunk return, which are the sole supply and return of the building, all the water passing through them. The 15-inch supply and return mains pass through a tunnel connecting the two buildings, the pipes being suspended on extra heavy rollers to permit of expansion. This tunnel is brick lined, arched, and is 6 feet high by 5 feet wide. After the 15-inch pipe enters the building it rises to the ceiling of the basement, and from this point one 4½-inch is taken first to supply the radiators situated on the floor of the basement to heat what is known as the children's refectory, playroom and sisters' refectory. Returns from these three rooms are carried back on base board into the tunnel direct and here connected with the main return. The main trunk continues, 14 inches in size, on the ceiling of the basement 130



An Extensive Hot Water Plant.—Fig. 1.—Basement Plan of St Joseph's Orphan Asylum.

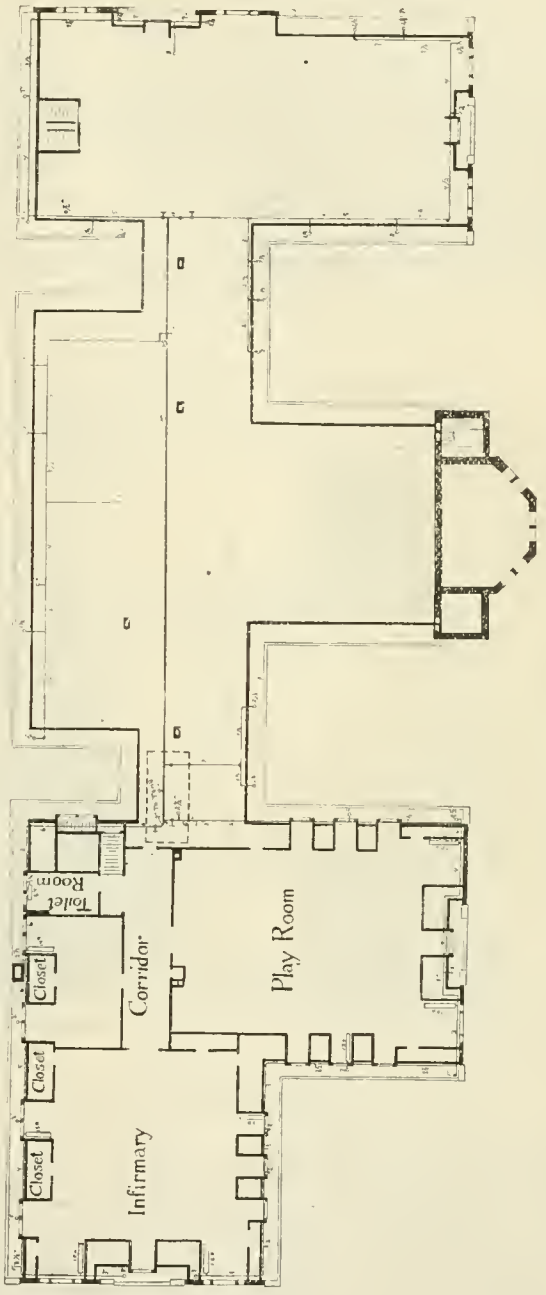


Fig. 2.—Attic Plan of St. Joseph's Orphan Asylum.

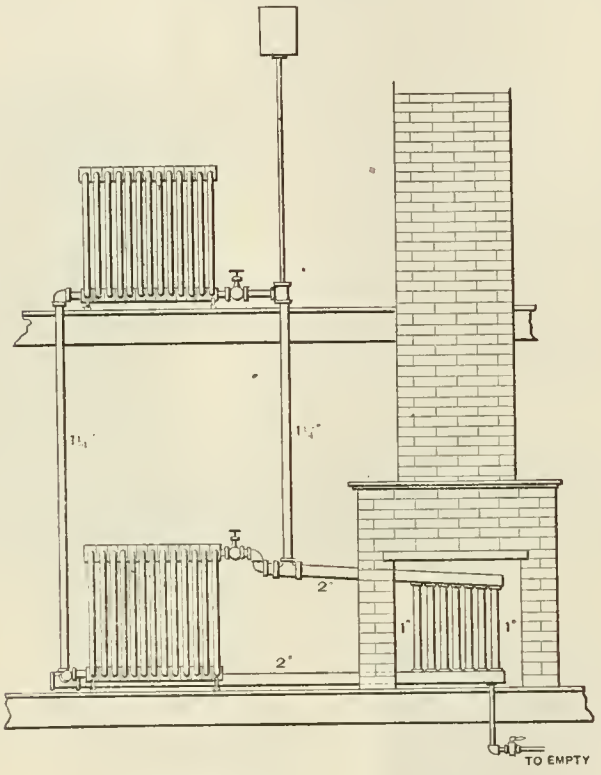
feet, and at this point a 5-inch main is taken off for the supply of radiation in the chapel. Then the main trunk continues, 13 inches in size, on the ceiling to the bottom of the trunk riser for 105 feet; this riser, being 13 inches in size, goes to the attic, a hight of 42 feet. A plan of the attic is shown in Fig. 2. From here one 5-inch and one 6-inch main are first taken off to supply all radiation on the eastern front part of the building. The trunk main continues, 12 inches in size, westward 36 feet, where a 5-inch main branch is taken off to supply all radiation on north side of the building. The main trunk continues, 10 inches in size, 110 feet, and at this, the higheat point, the expansion tank is suspended over the main. At this point two 6-inch mains are taken off, supplying all radiators in the western portion of the building. The total distance traveled by the water before the last radiation is supplied measures 726 feet, and upon several tests a loss of no more than 4° to 6° of heat was recorded by a special hot water thermometer placed at convenient points. The total distance traveled over by the water in main trunk from the beginning of flow to the end of return measures 1000 feet. It was found necessary to construct special fittings throughout this entire work to promote easy and rapid circulation. Any portion of this immense plant can be shut off by a system of valves, making any part independent of any other part. Standard radiators, with top openings, are used, the flow and return being in the same loop, and the entire system is vented automatically.



Radiators Heated from Open Fire.

Radiators Heated from Open Fire.

From G. T. K., *Radford, Va.*—A copy of *The Metal Worker* of January 27 having come to my hands, it is with interest I have noticed the article on "Radiator at Boiler Level." Herewith I give you a sketch showing two rooms heated from a water back in fire place on level or same floor as lower radiator.

The winter of 1892 the back having burned out of my fire place, in which I keep constant fire, the suggestion came, why not utilize this heat? As receiver for a plumbing company I had use of tools, and a friend gave me piping and radiators from a house which burned, and the following summer I put in this apparatus. It works entirely satisfactorily by heating one room at a time, controlling by valves, in very cold weather; in moderate weather both rooms are comfortable. The water back is made of 2 inch pipe for horizontals, and the down pipes, seven in number, are of 1-inch pipe. Two-inch pipe runs through chimney and is reduced to 1¼ inches for radiator connections. The return pipe from the upper radiator connects with 2-inch return at lower radiator, passing behind lower radiator, drops below floor level in chimney and in ash pit. An 18-inch grate hangs in the usual place. The system holds about 35 gallons of water and evaporates 1 quart a month. An emptying cock is placed in the cellar.

HEATING NOTES.

M. Mahony, Troy, N. Y., follows his March calendar card with a similar one for April. The variation is in the decoration, the one for the current month being truthfully representative of a showery day.

"What Are We Here For?" is the catching title of a pamphlet issued by the United States Heater Company, Detroit, Mich. It is needless to tell what the answer to this question is, for every one knows the Capitol, Hecla and Mascot heaters made by this firm. Following a dissertation on the boilers made by the United States Heater Company is a report on the Capitol hot water heater by Leicester Allen, a well known authority in such matters. At the close are extracts from letters telling of the good results attained by these boilers.

T. R. McMann, 56–60 Gold street, New York, is one of the old houses in the pipe and fitting trade, some men of the establishment having had nearly a half century's experience and the business having been started early in the "Sixties." The progressiveness of the house is shown in their method of handling some large extra double heavy pipe that weigh 800 pounds to the length that is being cut for an order. By means of a crane over the sidewalk, and an overhead railway in their shop, one man can bring these pipes to the machine and cut and thread them without assistance.

Johnson & Co., 71 John street, New York, agents for the Gurney Hot Water Heater Company, have a fine showroom in which they display a line of the 300 Series and Crown hot water heaters and Gurney radiators. The line is attractively painted and is displayed on platforms. The latest attraction is the new Gurney steam boiler, which is conspicuously located. A feature of the showroom that attracts not a little attention is the method of heating, which is from a small boiler of the 300 Series and radiators all on the same floor.

The Raymond & Campbell Mfg. Company of Middletown, Pa., manufacturers of the Sun heating boiler, have made some improvements in the boiler which will be appreciated by the trade. The draft door is now placed in the center of the ash pit door, and the position formerly assigned to the draft door is now occupied by a mica door, through which an attendant may observe the state of the fire when shaking down. The grate has been remodeled, its present form insuring durability and better combustion. The shaker is of entirely new design, being so adjusted that the lever works from the front and toward the attendant, instead of sideways as in the old style. The boiler has been generally redressed and presents a pleasing appearance. The company report that business in the boiler department last season assumed large proportions and sorely taxed their facilities for handling it. Anticipating their share of trade during the coming season they have added to the equipment of their boiler and erecting shop and have increased their facilities to quite an extent. At the present time they have upward of 200 boilers on the floor, in course of erection. They have just shipped a carload to Littlefield & Co. of Wakefield, Mass., and have other large orders awaiting shipment.

The Peerless is the name of a flange steel steam and hot water boiler which Geo. H. Bell & Co., 114 Nassau street, New York, are introducing. They will open a showroom at 41 Dey street May 1, and display a line of samples. The boiler has been previously noticed in our columns and is cylindrical in shape, consisting of an inner and outer annular water space, so arranged and connected as to cause an indirect draft. The outer water chamber extends up and forms a part of the boiler proper, which hangs directly over the fire. Pipes lead from the inner water chamber up into the center of the bottom of the boiler. The apparatus is provided with a labor saving grate, and both economy and great heating power is claimed for it. It is made in four sizes, with fire pot from 20 to 36 inches in diameter, and rated to carry from 200 to 1400 feet of radiation.

OBITUARY.

ARAD T. FOSTER.

As briefly announced in our last issue, Arad T. Foster, whose portrait is presented herewith, died suddenly, of apoplexy, at his home, 47 New York avenue, Brooklyn, N. Y., on March 29. Mr. Foster was well known and highly esteemed by the plumbing and heating trades, from his long connection with two prominent manufacturing concerns in this city catering to those trades—namely, the Haydenville Mfg. Company, 73 Beekman street, and Peck Bros. & Co., 47 Cliff street. At the time of his death Mr. Foster was president and general manager of the first named concern and vice-president of the latter.

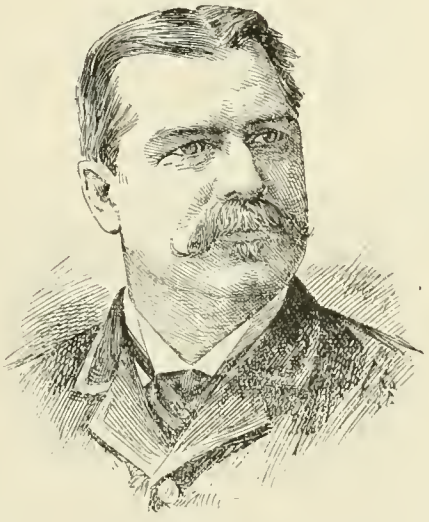
Arad T. Foster was born in Canada on April 12, 1837. His father and mother were descended from some of the most distinguished families in New England. The former was a renowned physician and became a member of the Canadian Parliament and Governor of the Dominion College of Physicians and Surgeons. Coming to the United States in 1864, Arad T. Foster became connected with the plumbing supply house of Peck Bros. of New Haven, Conn., as manager of the New York branch. For 30 years he was closely identified with this concern, of which he was vice-president at the time of his death. He was also president and general manager of the Haydenville Mfg. Company, brass and iron founders and manufacturers of water, gas and steam goods, a competing concern established in 1845 by the late Governor Hayden, at Haydenville, Mass., where the firm's works are still located. This corporation was bought out by Mr. Foster and the Peck Brothers in 1884 and has been owned and operated by them since that date.

Mr. Foster was for a number of years a member of the New York Metal Exchange, and was chosen president of the Manufacturers' National Association, at Pittsburgh, in 1886, to which position he was re-elected at each succeeding annual meeting. Since its commencement, his business career was a successful one. He was a man of cool judgment and dogged perseverance, united to the strictest integrity; generous in his nature, kind and sympathetic toward the unfortunate, and considerate to his employees. Of sterling Christian character, his religion was brightly reflected in all his domestic, social and business relations. In the words of the funeral address of his close friend and pastor, the Rev. Dr. Theo. L. Cuyler of Brooklyn, it was his religion "that made his business life so upright and his domestic life so happy. He had a large, warm heart: and I never knew a more kind and courteous gentleman. We cannot afford to lose such men as Mr. Foster. Such men are needed in the commercial world and in the community. He was a true man and bound his friends to him with 'hooks of steel.' He not only served God in the church, but he served Him all through the week by his life of strict integrity."

Mr. Foster was twice married. By his first marriage he had two promising sons, both of whom died in California, the younger having deceased but a few months ago. Mr. Foster's stepson, Cuyler K. Sanborn, was associated in business with him, and is now vice-president and secretary of the Haydenville Mfg. Company.

Mr. Foster was conspicuous in Masonic circles and a member of the Union League Club of Brooklyn. He was also an active and esteemed member of the Lafayette Avenue Presbyterian Church in that city.

On Monday, April 30, and Tuesday, May 1, during the day and evening, there will be a large exhibit of drawings made by members of the freehand, mechanical, architectural and carriage drafting classes, also manuscripts from the penmanship, bookkeeping, shorthand and typewriting, arithmetic, steam engineering and electricity classes of the Young Men's Institute, 222 Bowery, New York. All persons interested in such work are invited to visit the rooms and inspect the work done by the pupils. On Tuesday evening, May 1, the closing exercises of the classes will be held in the Institute Hall. Certificates of progress, diplomas and prizes will be awarded and there will be special music and addresses. The work of the school year 1893-94 has been very satisfactory, with an enrollment of about 635 young men in 11 studies. The committee are planning to add one or two new subjects to the curriculum for 1894-95. The fall term will begin October 3, 1894. Enrollment can be made any time during the spring, summer or early fall.



ARAD T. FOSTER.

The opening of the Chilean National Mining and Metallurgical Exposition, which was to occur at Santiago during the current month, has been postponed by decree of the Supreme Government until September next. The postponement has been decided upon in order to give opportunity for more thorough preparation by the Government, and because it was thought impracticable for exhibitors to prepare and forward their exhibits in the short time allowed. The exhibition will be divided into the following sections: Motive power, electricity, mining machinery, mechanical preparation of minerals, metallurgy, chemical industries, statistics and plans, and mining and metallurgical products. The Government will convey gratis to the exhibition all articles comprised in the above classifications which it may be desired to exhibit. The Government will also pay the passage money by sea and land of the workmen and operatives whom exhibitors may desire to send for the purpose of setting up and running the machinery and apparatus they exhibit. Application for space should be made to the Chilean Legation at Washington, D. C.

A New Aluminum Solder.—One of the most perplexing questions encountered in the development of the uses of aluminum has been that of soldering the metal. In many instances the effort has been made to get around the difficulty by riveting, a method frequently awkward and often leading to structural weakness. A series of tests were recently made of a solder which is being introduced by the Alsite Aluminum Company, 106 and 108 Liberty street, New York. Among the tests made were butt welds of sheets and plates, which under tension showed the soldered joint to be so well made that rupture took place in every instance outside of the joint. Strips connected by butt soldering were twisted in the vise without opening the seam, and soldered tubing has been successfully drawn recently. The surfaces to be soldered are cleaned by dipping in a hot solution of soda or potash, then dipped into nitric acid, rinsed in hot water and dried. Sometimes the surfaces are cleaned by filing the edges to be joined. The parts to besoldered are heated as hot as can safely be done without melting and a small portion of the solder is spread over the edges by means of a soldering brush, which should be kept heated during the process. The edges are then joined and more solder is applied and spread evenly over with the brush. During the entire operation the metal is kept as hot as possible, and it is completed when the solder becomes distinctly white or the aluminum assumes a reddish hue. Authorities on the working of aluminum have acknowledged that soldering by the Alsite process accomplishes results not hitherto attained.

Philadelphia is to spend some $14,000,000 this season on city improvement work of a permanent character. This includes a subway for the Reading Railroad, miles of new street pavement, a better sewerage system, &c. This work will furnish employment for some thousands of the unemployed in the coming months.

The approaching consolidation of some of the largest Chicago packing houses is stated to be a fact.

TIN PLATES.

American Tin Plate Manufacturers.

The following revised list of concerns engaged in the manufacture of tin and terne plates in the United States is extracted from the report of Col. Ira Ayer, special Treasury agent, for the quarter ended December 31, 1893:

Revised list of firms or companies engaged in tin and terne plate manufactures, December 31, 1893. (*a*, made sworn return; *s*, manufacture suspended; *b*, building; ‖, making or preparing to make black plates; †, make only black plates; ‡, manufacturing—failed to make sworn returns.)

NOTE.—In the following list are included the names of such firms or companies, only, as were manufacturing, or had begun building operations, prior to December 31, 1893.

A. A. Thomson & Co., *a*, New York, N. Y.
Alan Wood Co., ‖ *s* †, Philadelphia, Pa.
Aliquippa Tin Plate Co., *s*, Aliquippa, Pa.
American Stamping Co., *a*, Brooklyn, N. Y.
American Tin Plate Co., ‖ *a*, Elwood, Ind.
American Tin Plate Machine & Mfg. Co., *a*, Linfield, Pa.
American Tin & Terne Plate Co., *a*, Philadelphia, Pa.
Apollo Iron & Steel Co., ‖ *a*, Apollo, Pa.
Baltimore Steel, Iron & Tin Plate Co., *a*, Baltimore, Md.
Black Diamond Tin Plate Works, *a*, Philadelphia, Pa.
Blairsville Rolling Mill & Tin Plate Co., ‖ *a*, Blairsville, Pa.
Britton Rolling Mill Co., ‖ *b*, Cleveland, Ohio.
Burn Stamping & Mfg. Co., *s*, Chicago, Ill.
Canonsburg Iron & Steel Co., ‖ *a* †, Canonsburg, Pa.
Chicago Stamping Co., *b*, Chicago, Ill.
Chicago Tin Plate Mfg. Co., *a*, Chicago, Ill.
Cincinnati Corrugating Co., *a*, Piqua, Ohio.
Cleveland Tin Plate Co., *a*, Cleveland, Ohio.
Columbia Tin Plate Co., *s*, Piqua, Ohio.
Cumberland Steel & Tin Plate Co., ‖ *a* †, Cumberland, Md.
Duquesne Tin Plate Works, *a*, Pittsburgh, Pa.
East River Lead Co., *a*, New York, N. Y.
Falcon Tin Plate & Sheet Co., ‖ *a* †, Niles, Ohio.
Griffiths & Cadwallader, *a*, Pittsburgh, Pa.
Gummey, Spering & Co., *a*, Philadelphia, Pa.
Hughes & Patterson, ‖ *a*, Philadelphia, Pa.
Indiana Tin Plate Mfg. Co., *s*, Atlanta, Ind.
James B. Scott & Co., *a*, Pittsburgh, Pa.
Jennings Bros. & Co., Ltd., ‖ *a* †, Pittsburgh, Pa.
John Hamilton, *a*, Pittsburgh, Pa.
Kirkpatrick & Co., Ltd., ‖ *a* †, Pittsburgh, Pa.
Lalance & Grosjean Mfg. Co., ‖ *a* †, New York, N. Y.
Laufman Tin Plate Co., *s*, Butler Junction, Pa.
Locust Point Iron & Steel Works Co., ‖ *a*, Baltimore, Md.
Marshall Bros. & Co., ‖ *a*, Philadelphia, Pa.
Matthai, Ingram & Co., *a*, Baltimore, Md.
McKinley Tin Plate Co., *a*, Wilkinshurg, Pa.
Merchant & Co., *a*, Philadelphia, Pa.
Meurer Bros. Co , *b*, Brooklyn, N. Y.
Morewood Co., ‖ *a*, Gas City, Ind.
Morewood Tin Plate Mfg. Co., *a*, Elizabethport, N. J.
New Castle Steel & Tin Plate Co., ‖ *a*, New Castle, Pa.
N. & G. Taylor Co., *a*, Philadelphia, Pa.
Norristown Tin Plate Co., *a*, Norristown, Pa.
Norton Bros., ‖ *a*, Chicago, Ill.
Philadelphia Tin Plate Co., *b*, Philadelphia, Pa.
Phillips Tin Plate Co., *a*, Philadelphia, Pa.
P. H. Laufman & Co., Ltd., ‖ *a*, Apollo, Pa.
Pittsburgh Tin Plate Works, *a*, New Kensington, Pa.
Record Mfg. Co., *a*, Conneaut, Ohio.
Saunders, Fielding & Bond, ‡, New York, N. Y.
Somerton Tin Plate Works, ‖ *a*, Brooklyn, N. Y.
St. Louis Stamping Co., ‖ *a*, St. Louis, Mo.
United States Iron & Tin Plate Mfg. Co., ‖ *a*, Demmler, Pa.
Wallace, Baufield & Co., Ltd., ‖ *a*, Irondale, Ohio.
Western Tin Plate Works, *a*, Belleville, Ill.

Number of new companies	4

SCRAP.

THE QUARTERLY REPORT of the United States Iron & Tin Plate Mfg. Company, Demmler, Pa., to the Special Agent of the United States Treasury Department showa that during the quarter ending March 31, 1894, the output of the above concern was as follows: 2,020,767 pounds of tinned plates; 1,186,360 pounds of black plates for tinning, or a total of 3,207,117 pounds. Of this 2,867,648 pounds were lighter than 63 pounds and 339,469 pounds over 63 pounds per 100 square feet.

THE BRITISH BOARD OF TRADE STATISTICS for March, 1894, show the shipments of tin and terne plates from the United Kingdom to the United States during the month to have been 16,000 tons, as compared with 31,000 tons in March, 1893. The total tin plate exports to all countries during the month of March were 25,000 tons, as against 42,000 tons last year.

A PATENT has been granted in England to F. Player and D. Mainwaring of Ystalyfera, South Wales, for a new method of cleaning metal plates. The system is thus described: Pairs of rollers having surfaces of suitable material, the two rollers of each pair revolving at different speeds, are kept apart the proper distance by springs inserted between the bearings, the slack being taken up as the surfaces wear. The plate is delivered to the first pair, and is by them passed on to the next without the intervention of any carrying rollers. In consequence of the rollers turning at different speeds, both surfaces of the sheet are rubbed alternately by the top or bottom rollers of the successive pairs, or the rollers may be joined by belts which would be running at different speeds, and the plate would be simultaneously carried forward and rubbed between the surfaces of the upper and lower belts. For polishing tin plates it is only necessary to pass them through the machine, but for removing the grease the rollers or belts must be fed with bran or some other cleaning material.

The Production of Tin Plate.

The special report to the Secretary of the Treasury by Ira Ayer, special agent, Treasury Department, relative to the production of tin and terne plates in the United States during the quarter ended December 31, 1893, with comparative statements of production dated March 22, 1894, has been received, and shows the following results of his investigations:

A total of 39 firms manufactured 27,351,241 pounds of tin and terne plates proper, against an output of 27,145,430 pounds by 35 firms during the previous quarter. Of the output for the quarter, 15,907,669 pounds, more than 58 per cent., was made from sheets rolled in the United States. Of this amount, 15,309,009 pounds, more than 96 per cent., consisted of the class of plates weighing lighter than 63 pounds per 100 square feet. Of the commercial plates made during the quarter, 14,682,045 pounds were coated with tin, and 12,669,196 pounds were terne coated. More than 96 per cent. of all the commercial plates belonged to the lighter class. The quantity of American sheet iron and steel made into articles and wares tinned or terne plated was 1,244,707 pounds. This makes the aggregate output for the quarter from all sources 28,595,948 pounds; previous quarter, 28,198,293 pounds.

The production for the quarter subject to comparison with net imports under the recent ruling of the Department, inclusive of products from American sheet iron and steel, tinned or terne plated, was 16,553 716 pounds, as compared with 9,257,610 pounds during the previous quarter. The total for the two quarters was 25,811,326 pounds.

Three companies, Hughes & Patterson of Philadelphia, Pa.; the New Castle Steel & Tin Plate Company of New Castle, Pa., and the Western Tin Plate Works of Belleville, Ill., made their first sworn returns to the Government. The works at New Castle are complete, both for rolling and coating tin plates, and during the quarter operations were carried on in both branches of manufacture. The number of firms submitting sworn statements of production in excess of previous quarter was four. Besides the Western Tin Plate Works above named the Chicago Stamping Company of Chicago, Ill.; the Meurer Bros. Company of Brooklyn, N. Y., and the Philadelphia Tin Plate Company of Philadelphia were engaged during the quarter in erecting the necessary machinery for coating the plates.

Black Plate Production.—The production of black plate in the United States during the quarter was 19,679,910 pounds, of which 17,197,664 pounds, or nearly 90 per cent., belonged to the class weighing lighter than 63 pounds per 100 square feet. The production of the previous quarter was 11,355,368 pounds, of which 8,147,092 pounds, or about 72 per cent., was of the lighter class. The production of American black plates of the class weighing lighter than 63 pounds per 100 square feet was 2,989 472 pounds in excess of that of any previous quarter since the law became operative. Seventeen rolling mills made sworn returns of production, against 16 for the preceding quarter.

Consumption of American Plates.—Of the 39 firms making sworn returns of the manufacture of commercial tin and terne plates 21 used wholly American plates, with an output of 12,576,443 pounds; 12 used both American and foreign plates, with an output of 10,174,755 pounds, of which 3,331,226 pounds, or about 33 per cent.. was made from sheets rolled in the United States; six used wholly foreign plates, with an output of 4,600,043 pounds. Sixteen stamping or other manufacturing companies that use American sheet iron and steel in the manufacture of articles and wares tinned or terne plated submitted sworn statements of production, as against 18 during the previous quarter. The aggregate consumption of American plates in the various forms of manufacture was 17,152,376 pounds, which was equal to about 90 per cent. of the entire production of such plates during the quarter.

The following is a condensed comparative statement of the manufacture of tin and terne plates proper during the fiscal years ended June 30, 1892 and 1893, and the six months ended December 31, 1893:

Period of manufacture.	Amount made from— American black plate.	Per cent. American.	Foreign black plate.	Per cent. foreign.	Total.
	Pounds.		Pounds.		Pounds.
Quarter ended September 30, 1891	785,547	95.00	41,375	5.09	826,922
December 31, 1891	1,200,661	85.16	209,160	14.84	1,409,821
March 31, 1892	2,132,682	66.44	1,077,143	33 56	3,209,225
June 30, 1892	5,178,563	63.14	3,022,488	36.86	8,200,757
Totals	9,296,553	68.12	4,350,166	31.88	13,646,719
From September 30, 1892, to June 30, 1893	43,599,724	43.68	56,219,470	56.32	99,818,202
Quarter ended September 30, 1893	8,794,027	32.46	18,351,453	67.60	27,145,489
December 31, 1893	15,907,669	58.16	11,443,572	41.84	27,357,241
Totals for year 1893	54,337,889	.....	69,268,818	.....	123,606,707

The amount of American sheet iron and steel made into articles and wares tinned or terne plated during the same period was as follows:

	Pounds.
From July 1, 1891, to June 30, 1892, total	5,620,867
From July 1, 1892, to June 30, 1893, total	8,802,681
Quarter ended September 30, 1893	1,052,813
Quarter ended December 31, 1893	1,244,707
Total calendar year 1893	7,350,306

The amount of American black plates used in the aggregate manufactures during the period from July 1, 1891, to December 31, 1893, was:

Quarter ended—	Pounds.
September 30, 1891	1,914,764
December 31, 1891	2,159,991
March 31, 1892	3,620,343

September 30, 1893	9,846,840
December 31, 1893	17,152,376

A very instructive statement has been compiled, showing the rapid development of the production of sheet steel or black plates. The table below proves how rapidly American manufacture increased the output of plates lighter than 63 pounds per 100 square feet. It will be noted that while in the earlier periods the heavier plate represented by far the larger percentage, the quantity of light plates rose to its maximum, even during the panic period of the fourth quarter of last year.

Statement by Quarters of Fine Sheet Steel, or Black Plates, Produced in the United States from July 1, 1891, to December 31, 1893.

Periods.	Lighter than 63 pounds per 100 sq. feet.	63 pounds per 100 sq. feet and heavier.	Total.
Quarter ending—	Pounds.	Pounds.	Pounds.
Sept. 30, 1891	489,107	3,016,006	3,505,113
Dec. 31, 1891	679,584	4,593,416	5,273,000
March 31, 1892	1,696,595	4,909,370	6,605,965
June 30, 1892	4,761,641	6,067,537	10,289,178
Totals	7,626,927	18,586,329	26,213,256
Quarter ending—			
Sept. 30, 1892	4,821,180	4,202,277	9,023,457

Totals	25,344,756	5,690,522	31,035,278

Imports and Exports.—The quantity of tin plates and terne plates imported and entered for immediate consumption and of such as were imported on and after July 1, 1891, and were withdrawn from warehouse for consumption during the quarter ended December 31, 1893, was:

Imports.	Lighter than 63 pounds per 100 sq. ft.	63 pounds per 100 sq. ft. and heavier.	Total.
	Pounds.	Pounds	Pounds.
Tin plates	72,612,106	1,337,023	73,949,929
Terne plates	9,775,513	120,941	9,896,454
Totals	82,388,419	1,457,964	83,846,383

The quantity of tin plates and terne plates on which duties were paid and which were used in the manufacture of articles exported with benefit of drawback during the quarter was:

Exports.	Lighter than 63 pounds per 100 sq. ft.	63 pounds per 100 sq. ft. and heavier.	Total.
	Pounds.	Pounds	Pounds
Tin plates	32,663,671	86,540	32,750,211
Terne plates	4,423	.....	4,423
Totals	32,668,094	86,540	32,754,634

FLASHINGS.

Auld & Conger, Cleveland, Ohio, are sending out to the trade and to architects a card bearing a *fac simile* of the official ribbon which was evidence of a premium awarded to Auld & Conger by the World's Columbian Exposition for their Bangor roofing slate. The ribbon *fac-simile* is mounted on a heavy cardboard, on the reverse of which is a table giving the number of slate in any number of squares from ½ up to 60 squares. In connection with this table attention is also directed to the Mammoth Vein sea green slate and Bangor Union slate. In sending this advertisement to the trade, and more especially to architects, it is the desire of Messrs. Auld & Conger to persuade them to specify particular brands of slate for roofing contracts. It is well known that the practice of specifying tin plate brands is extensively carried out, and it is now suggested that the same plan might be followed to advantage in roofing slate. It is pointed out that to merely specify No. 1 roofing slate is altogether too indefinite, and it could be legally filled by the product from a hundred quarries, no two of which would be of equal value.

The strike of slaters in the Bangor district, Pennsylvania, mentioned last week, is practically over. Most of the men have returned to work. There has been no increase in wages.

The St. Paul Roofing, Cornice & Ornamental Company filed articles of incorporation with the Secretary of State, April 2, with a capital stock of $100,000. The incorporators are P. A. de Launirs, C. D. Pruden, A. K. Pruden, J. Seraen and H. Pruden.

George A. Ohl & Co., Newark, N. J., announce to cornice makers, sheet metal workers and the trade in general that they have executed a contract making them the sole manufacturers of the Vulcan Company's tools and machines. In their circular note they refer to the fact that heretofore the tools of this company have been restricted to the use of the members of the Vulcan Company, but now, in conformity with the contract mentioned, George A. Ohl & Co. are offering them to the trade.

The Illinois Roofing & Supply Company, 203 Lake street, Chicago, have just issued a 20-page catalogue of some specialties. Designs are shown of Imperial pressed steel brick, patent rock face brick and stone siding, corner trimmings of rock face and plain brick, continuous rock face stone for belt courses and window trimmings, &c. The designs illustrated are of a varied character, changes being made in details for the purpose of securing harmony with other details of building construction. Illustrations are given of buildings sided with the various materials, some with plain and others with ornamental cornice and side trimmings, &c. Instructions are printed how to lay pressed steel brick and put in window frames and doors. It is a most interesting catalogue on this subject.

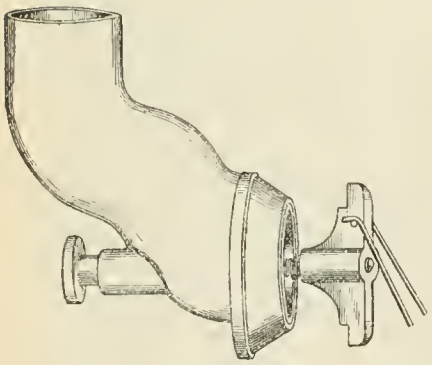
The Globe Ventilator Company, Troy, N. Y., report that they have recently placed three large sized ventilators on the new State Armory at Geneva, N. Y.

The Knisely & Yeldham Roofing Company, 68-74 West Monroe street, Chicago, are doing the galvanized iron cornice work on the building of Edward Ellis, 155-157 Madison street.

PLUMBING and GAS FITTING.

Closet Repair Coupling.

The accompanying illustration is of a coupling for connecting the water supply to an earthen closet on which the supply horn has become broken or damaged by settling of floor, jarring, or by accident. It has also been adopted by manufacturers of closets and used on new goods instead of the regular earthen supply horn. The coupling has been invented and patented by J. H. Savill, and placed on the market by Savill, Walls & Co., of 1229–31 Budden street, Philadelphia. It consists of four brass pieces, a supply arm with a tapering nozzle, over which fits a tapering rubber washer ; a screwed connecting bar, the upper end of which is ground to make a seat in the boss or lug cast in the supply arm, and a cross bar, having a wire spring attached. In use the cross bar is removed and inserted in the water way or flushing rim of the closet, the spring holding it firmly. The supply arm is then placed in the position it



Closet Repair Coupling.

is to occupy over the supply hole, and the screwed connecting bar passed through the supply arm and screwed into the cross bar until the rubber washer on the nozzle expands and makes a firm yet flexible joint. The head of the screw bar is ground in such a way as to insure a perfectly tight joint, even if the cross bar resting on the round of the flushing rim forces the screwed bar into a position out of direct line. The makers state that the coupling does not in any way interfere with the flush, but on the other hand tends to aid its right and left distribution. The coupling is made in two styles, bent, as in cut, and straight and to suit lead and iron pipe. The diameter of the bore is 1¼ inches.

James Meath, Samuel Dickson and Hugh McDonald, the Plumbers' Examining Board of Detroit, Mich., have been receiving applicants for certificates from master plumbers and journeymen, the journeymen being divided into two classes. The examination for a first class journeyman's certificate is nearly as rigid as that for master's certificate. All applicants are required to answer at least 60 per cent. of the questions. Those who fail are allowed to try again at any subsequent Friday evening on which an examination is held.

Plumbing Regulations of Memphis, Tenn.

Be it ordained by the Legislative Council of the City of Memphis that all plumbing work within the city shall be done and maintained under the following rules and regulations, divided into articles, viz.:

Article 1. No person shall proceed with any portion of drainage or sewerage, or alter old or new work, until they have filed at the office of the City Engineer a notice of the work to be performed.

Article 2. Such notice shall consist of a clear description of the work to be performed and be accompanied with a plan in duplicate, showing the different connections and locations of the different features, from the outlet at the main sewer to the termination above the roof.

Plans to be approved or rejected with the least possible delay within 24 hours—holidays and Sundays excepted—after date of filing.

Article 3. All plans must be legally drawn in ink on white paper. One vertical section in duplicate of plumbing arrangement will be sufficient if it can be made to show all the work ; if not, two or more drawings shall be furnished. Size of paper, 8½ x 12½ inches.

Article 4. No work shall be commenced until the plans are approved by the City Plumbing Inspector.

Article 5. After a plan has been approved, no alterations of the same will be allowed except on a written application.

Article 6. The City Plumbing Inspector must be notified in writing whenever any work is ready for inspection, and all work must be left uncovered and convenient for examination until inspected and approved by the City Plumbing Inspector, who will inspect the work within two working hours after he has set for inspection, provided a written notice was filed on the day previous, and he will issue certificate of inspection and approval at the time of final inspection.

Article 7. All plumbing work in new buildings and new work in old buildings, together with any old work which may be allowed to remain, shall be treated by the plumber, in the presence of the City Plumbing Inspector, with water or air, as the plumber may select. The tests to be as follows :

Water test to be applied from the roof of building to the end of iron pipe where connection is made with stone pipe. Air test, 15 pounds for 30 feet and under, and 20 pounds pressure for over 30 feet, vertical pipe. The work tested to stand the water test without any leakage, or stand the air test without any diminution of pressure on the gauge for ten minutes.

Note.—Any old work must be tested with water or air and found tight before it be allowed to remain and be incorporated with new work. This rule not to apply to additions to old work that is in good condition.

Article 8. Every building shall be separately and independently connected with the city sewers. Each tenement to be considered a separate building. All lines of 6-inch pipe in private property shall have not less than 10 feet of 4-inch pipe to closet or slop sink. This is for places where a number of small houses are on one lot.

Article 9. All pipes receiving the discharge from water closets, from 14 inches below the surface of the ground, except in roadways, where 2 feet will be required, to 6 inches above the eaves of the roof, must be of cast iron, 4 inches inside diameter, put away (20 feet minimum distance) from all windows and left open on top. All branches or extensions of sewer connections, whatever use they may serve, if more than 7 feet in length, must be ventilated by same size cast iron pipe to 6 inches above the eaves of the roof.

Article 10. All horizontal 4-inch cast iron pipe used for soil or waste, below or above ground, or placed on wall in cellars, shall have fittings and 4-inch brass trap screws on ends and on the main line, and not over 25 feet apart. All 2-inch cast iron waste pipe shall have Y-branches and 2 inch brass trap screws, as best located to clean out same.

Article 11. All stone pipe shall be of good quality vitrified salt glazed sewer pipe, free from blisters, thoroughly glazed and burned, straight, and of uniform texture, with good bells of sufficient size to insure proper jointing. All connections shall be made with Y-branches and all changes in direction with curved pipe or Y-branches.

Cast Iron Pipe.—All connections shall be made with Y-fittings. Sanitary tees can only be used on vertical pipes. No waste pipe shall be topped into soil pipe or trap of any other fixture, but shall have separate fittings (side outlet Y on sanitary T considered separate fittings).

No double hubs or sleeves to be used on vertical or horizontal lines of iron pipes used for the discharge of waste or liquid, except for connections.

Article 12. All joints of cast iron with lead pipes shall be made with a brass Raymond or other approved make of ferrule of same size as lead pipe set into the hub of the iron pipe and calked with lead, and to be attached to the lead pipe by a wiped solder joint.

All joints in lead pipes must be made with solder and wiped, if possible. All joints in cast iron to be made with packed oakum and molten lead, well calked, the lead to be at least 1¼ inches deep and joint made water and air tight. The joints to be left as calked until tested. All joints in earthen pipes shall be made with good hydraulic cement proportioned one to one with clean, sharp sand, gasket of oakum to be used on the end of each joint to keep the cement from entering the pipe. Care must be taken that the inside of the pipe is perfectly cleaned out before a connection is made with the house, the ends of all pipes to be kept closed during construction.

Article 13. All waste pipes, when less than 2 inches diameter, shall be of lead.

No pipe allowed less than 1¼ inches inside diameter. All waste and vent pipes 2 inches inside diameter and over the pipe and fittings shall be cast iron. Galvanized or rustless wrought iron pipe may be used for vent pipes. No waste pipe from refrigerator or other receptacle in which food or provisions are stored shall be connected with a drain, soil or other waste pipe, but must be separated therefrom, emptying into an open sink furnished with a trap.

All waste pipes from interior plumbing, exclusive of water closets and urinals, when less than 7 feet in length, can be discharged into an open trapped yard sink. If over 7 feet in length, ventilated pipe must be carried 6 inches above the eaves of the roof. If five or more fixtures are attached, waste pipe shall be 2 inches inside diameter or over.

Only one fixture allowed on 1¼ inch waste pipe, vent pipe to be same size as waste pipe.

Article 14. In all house connections the line of pipe as to grade and direction must be as straight as possible and located on same lot as house. For one line of pipe ditch to be not less than 18 inches wide ; for two lines, ditches must be 30 inches wide.

Grade to be not less than 1 to 50. In all ditches where the bottom is unsafe from any cause, as made ground, old wells and vaults filled up, &c., the grade of pipe must be made safe either by concreting, planking or the use of iron pipe, &c. All ditches must be properly graded, bells cut out and made clean of loose dirt.

If water pipe is placed in a sewer ditch it must be placed well to one side and above the sewer pipe and must be of extra strong lead. Iron water pipes must be placed in separate ditches.

Article 15. Any line of pipe connected with the city sewers if within 4 feet distance of brick wall of dwelling or any

building containing a cellar or basement or within 6 feet in solid clay, or 10 feet in made ground, of well or cistern, shall be of cast iron pipe. Stone pipe can be used under houses only where there are no cellars, and it is not inclosed, but rests on piers In passing through cellar or basement, pipe shall be attached to walls where possible.

ARTICLE 16. All water closets and separate fixtures must be trapped as close as possible, not more than 10 inches from weather ceil to floor. In no case shall cast iron hopper be leaded into pipe or trap, but shall be fastened down with brass screws; on cement or brick floors, iron hoppers shall be fastened on a flange with brass screws or set screw bolts. All earthenware hoppers and washout closets shall be fastened to lead or brass flange soldered to ferrule and fastened by brass screws or bolts. No fixtures allowed in cellars or basements where there is danger of back water from the city sewers.

ARTICLE 17. Cast iron traps with hand holes shall not be used. No bell trap, running trap or any trap depending for its seal on a movable part shall be used. No water closet shall be used which has an unventilated space of more than 100 cubic inches between two water seals, or which has such unventilated space of any capacity in which any part of the mechanism moves or the walls of which are not flushed at all points at each use of the closet. This includes the pan, Defiance and all other closets of similar construction.

ARTICLE 18. All S and P lead traps for small fixtures which are back vented from the crown of trap shall be of the same size as the water pipe. All 2-inch cast iron traps shall have trap screws.

ARTICLE 19 All kitchen sinks for hotels, restaurants, boarding houses, &c, shall have some standard grease trap attached. Grease traps are also recommended for use in private residences.

All yard slop sinks shall not be less than 2½ feet square, the frame filled in with broken stone or hard brick concrete tamped until solid and finished smooth with good cement; size of timbers 2½ x 12. See plan at engineer's office.

Catch basins, if allowed, to be located and built according to plans on file at the city engineer's office.

ARTICLE 20. In cleaning out house connections all broken or damaged pipe must be replaced with sound pipe, well oakumed and cemented, and must be inspected before ditch is filled in.

ARTICLE 21. All ventilation pipes on outside walls in public or private alleys shall come through the wall not less than 6 feet above the grade of said alley for protection from damage by passing vehicles. Before ventilation pipe is attached to the wall of building on adjacent property the consent of the owner of said property must be obtained.

ARTICLE 22. All 4-inch soil and ventilation pipe and fittings on the inside and outside of dwellings and buildings shall be cast iron pipe. No soil or ventilation pipe shall rest on stone pipe, but on cast iron bent or Y firmly supported and with a short piece of cast iron pipe 2 feet long attached horizontally to which the stone pipe connects. Vent pipes to yard closets shall not be less than 8 feet above the ground.

ARTICLE 23. All waste pipes must be trapped at each separate fixture, and as close as possible to fixture. Laundry tubs of not more than three parts to be considered as one fixture.

ARTICLE 24. All traps if found necessary to prevent syphonage or back pressure must be furnished with a vent pipe from crown of trap.

The vent pipe from a water closet trap must be at least 2 inches inside diameter. Where the back vent pipes from more than four water closet traps (other fixtures are included) are combined, or the vent pipe from four water closet traps is over 30 feet in length, the size of the vent pipe must be increased to 3 inches inside diameter, and must be carried 6 inches above the eaves of the roof, or may be run into soil pipe 5 feet above the highest fixture. In buildings over six stories high the size of vent pipe must be same as soil pipe, and must be carried 6 inches above the eaves of the roof. Other vent pipes from traps must be as large as the respective waste pipes, but where five or more are combined, or the vent pipe from one trap is over 30 feet in length, the size of vent pipe must be increased to 2 inches inside diameter and carried 6 inches above the eaves of the roof, or may be run into soil pipe 5 feet above the highest fixture. Where two or more fixtures are attached to a 2-inch waste pipe, all traps shall be back vented.

All washouts or other closets that have the trap attached above the floor, the trap must be back vented, syphon closet excepted. No running traps or back water valves or any manner of obstruction to the full flow of air through the whole course of pipe will be allowed.

ARTICLE 25. All water closets and urinals hereafter constructed in any building within the city of Memphis shall be placed in a room with not less than 12 square feet of floor space thoroughly ventilated. This room in dwellings shall not communicate directly by means of door or opening whatever with any sleeping room or sitting room or apartment which is occupied by any human being during as many as two out of 24 consecutive hours. The room shall have at least one window (2½ x 6 feet) to the open air, with upper and lower movable glass sash hung on weights, or window of same area on pivots (2½ x 3 feet).

ARTICLE 26. The discharge from hydraulic elevators must first enter a drum of sufficient size to hold the entire discharge, from which the water will pass to the sewer without pressure. The drum must be thoroughly trapped and ventilated.

ARTICLE 27. Steam or hot water from any source must first enter a receiving basin or condenser properly trapped and ventilated. The size of the basin may be reduced by the use of twin or double valve, allowing the escape of sufficient cold water at the same time with the steam or hot water to reduce the temperature.

ARTICLE 28. All water closets shall be located so as to have not less than 15 feet sewer connections to the city main and not less than 5 feet inside of property line.

ARTICLE 29 No trap vent shall be used as a waste or soil pipe.

ARTICLE 30. Overflow pipes from fixtures must be connected on inlet side of trap.

ARTICLE 31. All alterations and additions on old sewer, soil or waste pipes shall be made in accordance with these rules.

SECTION 2. Be it further ordained, that the foregoing rules and regulations be, and they are hereby, substituted in lieu and stead of the plumbing rules and regulations provided for in section 258 F, subsection 2, sub division G, and the said subdivision of said sub-section is hereby repealed.

TRAPS AND VENTS.

BOLGER & REGAN, plumbers and hardware dealers at Gloucester, Mass., were visited by fire April 6, and though their building and stock was not entirely destroyed, much damage was sustained.

JAMES E. MURPHY, a well-known plumber of Springfield, Mass., has opened a plumbing and tinning establishment at 138 Dwight street.

CHARLES SCOTT is going into the tin and plumbing business at Benson, Vt.

WM. MATHEWS & SONS have formed a partnership to conduct the plumbing and tinning business at Lebanon, Pa.

THE FIRM of G. W. Hazel & Co. have dissolved by mutual consent, and the G. W. Hazel Company have been incorporated to continue the stove, furnace, plumbing and tinning business at the old stand, 11 and 13 Church street, New Haven, Conn. The company have a capital of $15,000, which is held by Wm. H. Hazel, Julietta D. Hazel and Francea D. Hazel.

THE ARTICLES incorporating the Rock Island Heating & Plumbing Company have been filed in the recorder's office at Rock Island, Ill. The capital stock is $10,000, and the incorporators are T. F. Burke, John Joers and Ernest Wagner.

GEORGE LEONARD is going to move his plumbing shop to the corner of Second and Joliet streets, La Salle, Ill.

WILLIAM ROSE is about to open a plumbing shop at 3620 Jacob street, Wheeling, W. Va.

WILLIAMS & Co., 90 Ann street, New York, make a specialty of soapstone for every purpose, griddles, foot warmers and open stoves, and have a large trade in laundry tubs and sinks and wainscoting with the plumbers throughout the country.

DU BOIS & DARROW are a new house with an office and sample room at 61 Gold street, New York. They will make a specialty of plumbers', steam and gas fitters' materials.

SECRETARY MCNAB of Paterson, N. J., informs us that the Master Plumbers of Paterson and Passaic are now members of the National Association.

WE ARE INDEBTED to Charles Millar & Sons, Utica, N. Y., for a copy of their handsome catalogue for the year 1894. This volume is a substantial publication, bound in stiff boards and contains over 230 pages. The frontispiece is a handsome engraved portrait of Charles Millar, who was born in 1808 and died in 1890. In an introductory notice to the trade they state that they are largely interested in and are the exclusive selling agents for the Utica Pipe Foundry Company and are prepared to furnish all material for the construction of new water works or the extension and improvement of old ones. They also refer to the excellence of their lead pipe, as well as their solder, tin pipe and tubing. They act as agents for various manufacturers of patented and staple goods and have large warehouses with full stocks. The following condensed index indicates the extensive line of goods made and handled by this well-known supply house: Wrought iron pipe and fittings, iron cocks, iron body valves, steam brass work, engineers' supplies, plumbers' brass work, plumbers' copper work, lead traps, plumbers' earthenware, marble slabs, water closet apparatus, plumbers' iron work, pumps, cast iron soil pipe and fittings, vitrified sewer pipe, corrugated conductor pipe, ventilating or leader pipe, hose, belting and packing, steam heating, gas fixtures and fittings, tools, lead pipe and metals, cast iron water pipe and fittings. All of the goods are illustrated, descriptive particulars being given where necessary, and in all cases full lists of sizes and prices. A very attractive feature of the book is the light green tinted paper that is used.

THE EDITION of the illustrated catalogue of the Haydenville Mfg. Company, 73 Beekman street, New York, issued this year, is probably the largest ever issued by a plumbers' supply house. Between 25,000 and 30,000 copies have been put in circulation.

SANDS & HOULE opened their new plumbing establishment and hardware store in the Goodwin Block, on Main street, Biddeford, Maine, last Saturday.

B. & H. H. SOMMER are arranging a fine line of plumbers' marble and sanitary ware at their new showrooms, 50 Cliff street, New York. They import Italian marble and English water closets, lavatories, Yorkshire laundry tubs and white porcelain sinks, tubs and lavatories and iron enameled roll rim baths. Pink Knoxville and Tennessee marble, as marble for floors and walls, in addition to plumbers' slabs, are a specialty.

BENTON R. DIBBLE AND CLINTON HURLBURT have opened a plumbing establishment in Winsted, Conn.

ROBERTS & SIMMONS is a new plumbing firm just opened for business in the Eitlegeorge row, 18 La Salle street, Aurora, Ill.

W. H. HITCHCOCK has added a stock of tinware to his stove and plumbing business on Central street, Palmer, Mass.

STOVE TRADE NOTES.

The New England Stove Trade.

Trade in New England is barely holding its own. As was expected, the first quarter of 1894 compares unfavorably with the same period of the previous year, although the net falling off is not so great as was feared. Most of the Eastern manufacturers are busy preparing new goods, but these will not be made in any great quantity until the season is further advanced and the probable demand can be more accurately gauged. Jobbers report a fair amount of business, particularly in gasoline stoves and refrigerators. The former are selling in much larger quantities in this territory than ever before, but the demand for the latter is not so great as last season. Sample orders so far constitute the bulk of the trade. The repair trade is between seasons and a light business is doing in this line. Reports of collections are rather conflicting, but generally speaking there is no improvement and possibly a slight decrease; however, hand to mouth buying naturally favors better collections, as small bills are paid more promptly than large ones. The furnace trade is dull and the prospects are rather uncertain, although a fair demand is expected.

The outlook for building in this vicinity as regards smaller houses is not particularly promising. Speculative builders who in former years have erected a large number of low cost houses and disposed of them to parties of moderate means, accepting a few hundreds of dollars in cash and taking mortgages for the balance, find that owing to the hard times it is almost impossible to make sales to this class of people, and the fact that a number of those disposed of last season have come back on their hands through the inability of the purchaser to continue his payments is resulting in more conservatism among the builders. Larger work, however, such as school houses and other public buildings, bids fair to be active during the spring and summer. Many towns and cities throughout New England are making liberal appropriations for public works, and from this source the steam and hot water men expect to derive considerable business.

Taking the several branches of the trade together, and considering the general state of things, there is really little room for complaint. Of course, business is unsatisfactory, but that is true of almost every line, and it does not appear that the New England stove trade is feeling more than its natural share of the existing depression.

New Trade-Mark.

The Western Stove Mfg. Company, St. Louis, have adopted a new trade-mark, which we illustrate herewith. The center of the trade mark represents an apple with a short stem and leaves attached and surrounded by rays. The name and address of the firm, with an indication of the line of goods manufactured, appears on the side of the

Trade-Mark of the Western Stove Mfg. Company.

apple. The design is neat and attractive, and will doubtless meet the general approval of the trade.

St. Louis Stove Trade.

The stove trade at this time of the year is at about its lowest ebb, and in ordinarily good times it is difficult to market stoves, while now it is particularly so. Manufacturers, however, are living in hopes of better times, so much so that at least 80 per cent. of the producing capacity of the stove trade in this city is at present employed. Only one foundry is closed down, and that the smallest of the four located here. The other three are running nearly, if not quite, full. With the enterprise which characterizes the stove trade at large, the local foundries are at work on new goods, which will make their appearance in the course of the next two months. Reports from their traveling men indicate that the stock of stoves in retailers' hands was never before so light, and with any kind of improvement in the general commercial situation, no matter how slight, the stove trade will be quick to respond. It is pretty generally agreed that the sales of stoves during the year 1893 were from 25 per cent. to 30 per cent. less than the year immediately preceding, so that it seems reasonable to assume that those who postponed buying last year will be forced to become purchasers this year, even if unwilling ones. Many stoves were used last year which ordinarily would have been dispensed with, and they cannot possibly be made to do service again. It is a little too early to make any predictions regarding the volume of this year's business, but it is safe to assume that it will show material improvement in comparison with last year.

As regards gasoline stoves there is not much cause for complaint. The largest local manufacturer, and the largest perhaps in the country, informs us that their business at this writing is very close to last year, and the indications for a continuance of this activity are encouraging.

Albany Gossip.

Our Albany correspondent, writing early in the week, says: A visit to the manufacturing plant of the Perry Stove Company shows trade in this section to be reviving, and indicates the increase of hopeful features. The plant started up, after inventory and repairs, on February 5 and has been in operation ever since. The force of molders is the same as the number employed at the time when the concern shut down. The company have been largely engaged in manufacturing their popular lines of oil and lamp stoves, to which they have added one entirely new size, the Royal F, a four-burner stove, full nickeled, with large permanent extension top, having four full sized 8-inch boiler holes. The stove has met with great popularity. The Perry line of Royal lamp stoves has been greatly improved by the addition of a very convenient lighting device and the enlargement of the smaller size. This line is now furnished in polished nickel and is a very complete and serviceable assortment of oil goods. The Jockey is a new addition to their line of lamp goods, and is of medium price.

The Shoo Fly is also a new low priced line. The company are making two new lines of hot plate gas stoves — the Argand and Fire Fly. These are neatly finished in nickel and plain iron, are simple in construction and powerful in operation, possessing many special and useful features As a specialty the company have brought out a double oil stove mounted on polished nickel or a japanned base, with either two or four hole removable extension top. They have also made new and improved extension tops and furniture for their oil and lamp stove lines. The superintendent of the company, R. Z. Liddle, says that while their plant has been very busy with spring goods the general trade has not been up to the standard, but they believe they have had a large percentage of the sales in these lines and hope for improved

conditions. They are at work on some special improvements in ranges and parlor goods, which they will bring out later, and which, they believe, will meet with general favor.

Mason & Davis Company,

72-76 Lake street, Chicago, have just issued their catalogue for the season of 1894. The products of this company comprise wrought steel ranges, charcoal broilers, laundry stoves, gas ranges and hot air furnaces, all of which are put on the market under the brand "M. & D." The catalogue now being distributed is the largest thus far issued by the company. It consists of 76 pages, octavo, illustrated with engravings of more than usual excellence and bound with an olive colored paper cover. The first part of the catalogue deals with wrought steel ranges, adapted to the use of any kind of fuel. The ranges shown cover a great variety of styles, such as 4-hole and 6-hole family ranges with square tops and either high or low warming closets; the same with reservoirs at the side or with a galvanized iron tank on brackets; others with handsome sheet iron canopies and with broilers on brackets at the side; large ranges for restaurants and hotels, running from six holes up to as many as may be desired. The gas ranges are all built in cabinet style, the smaller ones having a single oven and four cooking holes, while larger ones are made with double oven and six holes. Several kinds of combination ranges are shown, in which half the range is for use with coal or wood, while the other half is equipped for gas. The M. & D. gas ranges have a number of special features, such as an elevated broiler, a swinging oven burner which can be drawn out for lighting, and water heaters which can be used at the same time for cooking purposes. The water heater is composed of seamless brass tubes, which heat quickly and are economical in the use of gas. The combination ranges are so built that water can be heated either on the gas range or the coal range side, either being always ready for use. These ranges have grown steadily in favor since they were first brought out as an experiment to see whether there would be a sufficient trade in them to warrant their regular manufacture. A charcoal boiler is a separate article of manufacture. Laundry stoves of several styles are shown. The M. & D. furnace is intended for either hard or soft coal, is made with a dome of steel plate, and is fitted with a circular cast iron radiating section around the fire pot, which acts as a return flue and radiates the heat that remains after leaving the body of the furnace. It is made in four sizes. The catalogue closes with several pages of illustrations of repairs for all kinds of M. & D. ranges.

ODD PLATES.

The Baxter Stove Company of Mansfield, Ohio, state that the fire which on April 5 destroyed a portion of their storage warehouse, causing considerable damage to the building and to their stock of Banner coal and wood stoves, did not affect the operating department, nor did the fire reach their stock of Monarch vapor and gas stoves. No delay, therefore, will be caused in the filling of orders for these goods, as the company will continue running without intermission, and orders placed with them for either Banner or Monarch stoves will be promptly shipped. The fire was caused by an explosion in the japanning department, but the loss is fully covered by insurance. In a circular letter which the company have issued under recent date, they say they are prepared to offer a large discount on such Banner cooks and heaters as were damaged by water and on which a large force of men is at work cleaning and restoring them to a marketable condition.

Eugene Munsell & Co., 218 Water street, New York, are remodeling the back part of their premises used for general office purposes. The entire portion heretofore used for clerical work has been torn out and replaced with narrow ash boards, running up two stories and covered with a glass roof. The wood work will be finished in natural color. This rearrangement will insure plenty of light and good ventilation.

The Marion Stove Company of Marion, Ind., invite the attention of dealers to their Retort self feeding stove, adapted for using any kind of soft coal as a fuel. The heater is made in two sizes, Nos. 16 and 18, embodies the modern features and is ornamented in a neat and attractive manner.

Barstow Stove Company, corner of Beekman and Water streets, New York, are the special agents for Jewel gasoline stoves made by George M. Clark & Co., Chicago, Ill. The line covers a large assortment of process and cabinet ranges, step, medium and junior medium stoves, junior safety and Jewel-Acme medium and safety stoves, Jewel ranges and picnic stoves, &c.

The Simonds Mfg. Company, 50 Cliff street, New York, have made their sample room very attractive. The walls are decorated with their register faces in various designs, white and black enameled and electro plated in brass, copper and oxidized, artistically arranged to secure good effect. Their line of hot air furnaces are finished in white and gilt, and their ranges with a deep black polish make a very pleasing contrast. A new catalogue of their goods soon to be ready for distribution is said to be very handsome, and may well be preserved as a souvenir.

Eugene Munsell & Co , 218 Water street, New York, have issued an illustrated price-list of gas stoves and ranges for this season's trade. Among the goods referred to is a line of Favorite Manhattan gas ranges, with two, three and four top burners, and with or without hot water heater. They also direct attention to an improved method of mounting kitchen boilers for circulating hot water, in connection with combination coal and gas ranges, so located as to economize kitchen space. It is known as the Graves Ronalds boiler, and in itself resembles the usual upright pattern. It is supported by a cast iron shelf about 2 feet above the top of the range at either the right or left hand corner, projecting about one-third the diameter of the boiler beyond the range. From the floor to the top of the boiler is from 76 to 80 inches, depending on capacities of 18, 24, 30, 34 and 40 gallons. Hot water is drawn from a faucet placed at the lower water back connection.

W. M. Crane & Co , 838 Broadway, New York, have enlarged their capacity for doing business by adding an annex in the rear of their present quarters in size 25 x 30 feet, which they hope to occupy before May 1.

George Starrett, 227 and 229 Water street, New York, has been appointed Eastern agent for the ranges manufactured by the Electric Oil Stove Company, Homer, Mich. These ranges are made in both two and four hole sizes, in a number of styles with and without open work, warming attachments at back and sides. The top is of cast iron, with black enameled and ornamented steel frames, fitted with casters. A long horizontal round tank, holding 1 or 2 gallons of kerosene oil, according to size, feeds the lamps, which with the tank are supported upon a sliding shelf, which can be drawn forward for filling or trimming. The central draft brass burners are supplied with 10-inch round extra heavy wicks, giving an intense heat with no perceptible odor. The covers or lids are 8 inches in diameter, with 4 inch removable center lids, convenient for heating cups, teapots and other small utensils. The lamps have mica fronts, and in the tank is a float to indicate the volume of oil.

Henry Gleason, 106 Beekman street, New York, has just returned from a tour of the Western stove foundries, covering a period of about three weeks. The principal object of the trip was to inform himself concerning what is latest and best in independent gas stove connections, embracing cocks, pipes, nipples, caps, air mixers, &c. He has recently taken the selling agency of Simpson Fry Mfg. Company of Brooklyn, N. Y. This is in addition to the following lines, for which he has long been agent: New Jersey Lamp & Bronze Works, stove urns and bronze figures; Trent Tile Company, stove tiles, and Matthews Mfg. Company, stove knobs, hinge pins, &c.

J. H. Cort & Son, 220 and 222 Water street, New York, manufacturers of and dealers in cooking and heating apparatus, are about to vacate the premises so long occupied by them at the corner of Water and Beekman streets, and move to their factory in Brooklyn, corner Adams and Water streets. They will make a specialty hereafter of manufacturing exclusively such goods as gas ranges and oil heaters.

The Tracy Gas Stove & Furnace Company of East St. Louis, Ill., have recently been incorporated, with a capital of $50,000. The incorporators are: L. J. Tracy, Theodore Hebus and Charles Elam.

The Bain Stove Company, Charleston, Ill., was recently sold to the Charleston Building & Loan Association for $13,000. It is intimated that people in Charleston will operate the works.

E. B. Colby & Co., 237 Water street, New York, have been appointed Eastern agents for the Cable and Cable, Jr., oil stoves. These are made in one, two and three wick styles, with cast iron oil tanks, at prices very close, they say, to those made of tin. The Junior pattern for gasoline is made in one, two and three burner styles. The feature of this construction, as stated by the agents, is that the tank must be lifted off to fill it, closing automatically as this is done. When filled it must be put properly in place, when the connection opens automatically. This prevents filling while attached to a lighted stove, as the stove will burn full 10 minutes after the tank has been removed. They are also offering as agents a full line of the Gurney refrigerators, made by the Gurney Refrigerator Company, Fond Du Lac, Wis. One

of the characteriatics of these refrigerators is the removable patented galvanized ice compartment, which can be instantly lifted out for cleaning. At the left is also a cast iron tank within the compartment, porcelain lined, for refrigerating drinking water, to be drawn at will through a faucet, the water being cooled by the proximity of the ice.

W. M. Crane & Co., 838 Broadway, New York, manufacturers of and dealers in hotel, *café* and restaurant gas appliances for cooking and heating purposes, are continually bringing out novelties in this line adapted to public or private use. They recently got up to order for D. B. Wesson, Springfield, Mass., the well-known pistol manufacturer, an elaborate laundry stove to heat six irons separately, having a capacity equal to the needs of a family of ten people. A copper boiler was placed in the center, and the entire apparatus handsomely nickeled. One of the several departments of their business is the fitting up of banks, trust and insurance companies, exchanges, &c., who provide their employees with a warm noonday meal, with gas cooking outfits. Among those put in recently in this city are the Fourth National Bank, Farmers' Loan & Trust Company and Bank of the Metropolis, some of whom provide for upward of 100 people. This company have just completed a series of experiments in connection with a gas furnace for heating an entire house. These will be offered as a substitute for coal furnaces, necessitating no alterations in flues, registers, &c.

Fletcher, Russell & Co., Limited, Thynne street, Warrington, England, favor us with a copy of their catalogue for March relating to gas heating appliances. In its general make up it resembles previous editions brought out by the company, is profusely illustrated, and clearly indicates the line of specialties manufactured. Attention is invited to their Standard high power concentric ring burners, which are suitable for furnaces and for use under vessels of large diameter. They are made separate and independent of each other, or four burners can be fastened together and used as one. Mention is also made of their triple concentric burners, 8½ inches in extreme diameter and consisting of three burners in one casting. A great deal of interesting matter relative to gas cook stoves and heaters is given, and while the catalogue is issued for circulation among the English trade, it contains many things likely to interest dealers on this side of the water.

Dispatches from Reading, Pa., are to the effect that the trouble recently referred to as existing among the mounters at the works of Orr, Painter & Co. is practically at an end. Some of the mounters have returned to work, and at the time the dispatches were sent it was thought everything would be settled in a few days. All the other departments are in full operation, and it is intimated that the Milmont plant will be running full in the not very distant future

The Gobeille Pattern Company of Cleveland, Ohio, are distributing an advertising novelty which is decidedly unique in its way. It consists of a piece of white pine 4 inches square and $\frac{5}{16}$ inch thick, planed perfectly smooth and bearing upon one side a postage stamp and the name of the addressee, while on the other side is the printed matter, which appears in colored ink. In the upper right hand corner is a *fac simile* of the company's trade-mark, and in the opposite corner are the words "Inside Information," and below them in parenthesis, "On the Square." The body of this wooden postal card is occupied with the following: "Do you know that when business starts up there will be a lot of new goods on the market and the old styles will not go? The best concerns are quietly adding to their line either entirely new or freshly decorated patterns. A word to the wise is sufficient." This is signed with the name and address of the company.

Giblin & Co. of Utica, N. Y., have issued from the press a very neat catalogue, oblong in its general shape and bound in colored paper covers, illustrating and describing the furnaces which they manufacture. These include the Standard Rival, Standard Junior, Standard Smokeless, Rival Junior and Smokeless, some of which are combination heaters. The goods are carefully illustrated and fully described, the matter being arranged in a way to prove interesting and instructive to the dealer.

The Michigan Vapor Stove Company of Grand Rapids, Mich., have issued a very pretty catalogue for 1894. Their line of stoves comprises steel frame single and individual generators, consisting of three-burner with step, two-burner with step, two and three burner square top, two and three burner high juniors, and two and three burner juniors. A peculiar feature of these stoves is their equipment with a tank which can be taken off for refilling. This enables it to be taken out of doors to be refilled, so that no gasoline whatever is exposed in the house. The burners used on the step stoves are of a special pattern, denominated jet cone burners, which divide the flame into a large number of jets, thus distributing the heat evenly over an extended surface. Full repairs are furnished for all stoves. The catalogue also treats of stove furniture in considerable detail.

The Howard Furnace Company of 210 Water street, New York, have lately completed the contract for heating the Fourth Avenue M. E. Church, corner Fourth avenue and Forty-seventh street, Brooklyn, using two of their largest size combination furnaces with hot water radiators in each of the classrooms of the Sabbath school building, also in the church audience room, together with the lecture room, ladies' parlor and pastor's study. The company have also put in a number of other combination furnaces in private dwellings and have just completed a dwelling for a prominent architect of Philadelphia. They also placed one of their combination furnaces in King's Hotel, Amityville, L. I., in the early part of the winter. They have received very flattering commendations of the same for the efficiency of the work in extreme cold weather. The company now have under contract a school house on Long Island.

A. Weiskittel & Son, Baltimore, Md., favor us with a very neat card having a gilt border and embellished with illustrations of a Fire King cabinet gas range and a Fire King table stove. The printing is in two colors, forming a pleasing contrast and giving a rather rich effect. There are illustrations of the new Fire King gas burner noticed in these columns a week or two since. In the lower left hand corner of the card is a *fac-simile* of the firm's trade-mark, while at the right appear their name and address. The opposite side of the card carries a number of reasons why gas should be used for a fuel.

S. S. Jewett & Co. have removed their office and salesroom from 38 and 40 Lake street to 2050 Grove street, Chicago, occupying for that purpose a portion of their new warehouse. Its location is at the south end of the Canal street bridge over the south branch of the Chicago River.

The Fuller Warren Company's Chicago headquarters will be removed on May 1 from 48 and 50 Lake street to 147 and 149 on the same street.

Cribben & Sexton, 75 and 77 Lake street, Chicago, will remove their office and salesroom to their new building at 50 to 53 Erie street, May 1.

Charles F. Bartlett, Tenth and Filbert streets, Philadelphia, Pa., issues a circular of liberal proportions, the object of which is to bring his name and business prominently before the mind of the dealer when in need of anything in the way of heaters, ranges and open grates. Mr. Bartlett has been engaged in the business indicated for nearly half a century, and states that his workmen are only those who have had experience in the making of goods of this kind. The circular illustrates and describes the Tobasco, a new and improved portable furnace with shaking and dumping grate, the London Café wrought steel portable range, made with single or double oven, the London Kitchener, suitable for private families or public institutions, the London Café wrought steel gas ranges, the Vesper open fire place, the Perfection gas grate and the Veteran and Bartlett furnaces. One side of the circular is devoted to a list of names and addresses of some of the people in Philadelphia and vicinity who are using Bartlett ranges and furnaces.

John D. Rise, formerly cashier of the Lebanon Trust and Safe Deposit Bank, has recently been appointed the financial manager of the Lebanon Stove Works of Lebanon, Pa. Mr. Rise took charge of the affairs connected with his new position on Monday, April 9. He was appointed to succeed J. M. Reilly, whose resignation was referred to in these columns a short time since.

Walker & Pratt Mfg. Company's foundries, at Watertown, Mass., commenced this week to run four days out of six, instead of shutting down altogether, as was contemplated.

The Wm. G. Fischer Mfg. Company of Kokomo, Ind., have brought out a new four-hole wrought range, which they have christened the No. 248 Columbian. The American shield appears on the oven door, the corner pieces are decorated with stars and stripes and an outstretched eagle surrounded with stars appears on the feed door. The manufacturers, therefore, allude to it as "the banner range of 1894." It is well made, having a drop oven door, patent drop feed door, triangular grate, gravity latch, nickeled front guard rail, high shelf, flues lined with heavy sheet asbestos protected between two sheets of steel, and the body made with round corners closely and substantially riveted. The oven is so made that it is claimed to be proof against dust, ashes, smoke or gas. This range is made for soft or hard coal, coke, wood or natural gas.

A most excellent advertising scheme has been devised by the Michigan Stove Company. They furnish to any hotel keeper a full set of dating stickers, covering every day from now until the end of the year, to be used on his register of guests. They are printed in

carmine, are very neat in appearance, give the day of the week as well as the full date, and thus cause the date to stand out prominently on the page. Each sticker is 7 inches long by ¾ inch wide, printed on perforated paper so as to be easily torn from the sheet and gummed for instant use. The sole suggestion of the Michigan Stove Company's connection with the date line is their Garland trade mark in the center, but it is of modest proportions and rather ornamental.

THE GIRARD STOVE & FOUNDRY COMPANY of Girard, Ohio, contemplate the erection of a larger building, and there is some discussion of the advisability of removing to another locality. Youngstown has hopes that in such an event the advantages of that point will not be overlooked.

THE WORKS of the Mississippi Valley Stove Company, at Fulton, Ill., have been completed, and manufacturing operations will begin very shortly. This concern is the transplanted Ohio Stove Company, formerly of Tiffin, Ohio.

Decline of the Brick Set Furnace.

BY A. W. GLESSNER.

President Excelsior Steel Furnace Company, Chicago.

A feature of the furnace business of to-day that has received a good deal of attention at the hands of the trade is the decreasing demand for the brick set furnace in favor of the portable furnace. In some sections of the East, and particularly in some of the larger cities of Ohio and Pennsylvania, the brick set furnace is still being put in in considerable numbers, but throughout the larger portion of the country at the present time, and particularly in the large and growing cities of the West and middle West the brick set furnace is becoming almost as rare as the buffalo. The brick set furnace has done a great work in its day, but the requirements of modern dwellings are such as to make it an undesirable fixture in the basement of the city dwelling of to-day.

Undoubtedly at the time when the brick set furnace first came into popularity this style of furnace was much more economical in its consumption of fuel than was the portable form of furnace, for the reason that then the improved casings and bonnets now in use had not come into use, and a large proportion of the heat generated by the portable furnace was practically lost.

Furthermore, there has come a decided change in the uses to which the modern basement is put. A large portion of the dwellings erected at the present time in towns and cities are supplied with water systems as well as plumbing and drainage systems and the pipes pass up through the basement, and in not a few cases, where brick set furnaces had been installed in houses before the introduction of water or drainage service, it was found that after the service had been introduced there was great liability of freeze ups. There should be sufficient warmth in the basement during the most severe winter weather to prevent the freezing of the pipes; and whereas a brick set furnace might, and undoubtedly would, effect a very slight saving of fuel over the portable form, this economy of fuel will be more than counterbalanced by the loss, annoyance and damage caused by a single freeze up in the course of a winter. I know of one manufacturer of furnaces who formerly made brick set furnaces in large numbers, who has not had his patterns for them in the sand for the last two years. The tendency to abandon the brick set furnace seems to be a good one, and not only does the portable furnace supply in every respect the requirements of the modern dwelling, but it does so at a considerably lower price.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

WM. G. MCLEOD of Cambridge, Mass., will erect a four-story apartment house of twelve suits of rooms, each to have a bathroom and an independent system of heating.

MAY & HARRIMAN, plumbers, were the lowest bidders for the work of equipping the water closets in the court house at Anderson, Ind. They will put in ten closets and eight urinals for $913, and make all connections with the sewer.

SEALED PROPOSALS will be received at the office of the Supervising Architect, Washington, D. C., until May 2, for work including low pressure steam heating and mechanical ventilating apparatus for the United States Court House and Post Office building at Paris, Texas. Drawings and specifications can be had from the Supervising Architect, Washington, or from the superintendent at Paris.

BIDS will be received by the School Board of Defiance, Ohio, up to April 20, for heating and ventilating the new six room school building in the Third Ward. Bids for both hot air and hot water will be received.

PROPOSALS will be received up to April 21 for the plumbing and hot water heating plant in the new City Hall at San Francisco, Cal.

THE Q N. EVANS CONSTRUCTION COMPANY, 41 Dey street, New York, have been awarded the contract for heating and ventilating the Gibson district school house at Boston, Mass. A steam plant on the blower system will be installed, at a cost of $12,523.

PROPOSALS will be received until May 1 for heating the Bellefield and Soho schools at Pittsburgh, Pa., with a steam or hot water plant.

THE J. L. MOTT IRON WORKS, 311 and 313 Wabash avenue, Chicago, are shipping a large number of bathtubs, water closets, lavatories, slop sinks, &c., to the new St. Nicholas Hotel, St. Louis.

THE WELLS & NEWTON COMPANY, 274 Dearborn street, Chicago, have secured the plumbing contracts for the stations of the Metropolitan Elevated Railroad at Halated street, Center avenue, Laughlin street and Marshfield avenue.

THE JOHN DAVIS COMPANY, 69 to 79 Michigan street, Chicago, have contracts for steam heating in the flat building of John Fiske, Forty-seventh street and Champlain avenue; station of the Lake Street Elevated Railroad at Rockwell street, and W. H. Purcell's buildings at Kensington, Ill.

THE HERENDEEN MFG. COMPANY, 131 Lake street, Chicago, have received an order from the Sanitary Heating & Plumbing Company of Peoria for three No. 9 Furman hot water boilers, to be placed in school buildings at Rushville, Ill.

JACOB G. WEBER, 244 North Clark street, Chicago, has the contract for plumbing in the apartment building of Richard F. Teale, Monroe street and Ogden avenue.

THE WINDSOR HEATER COMPANY of Galena, Ill., have secured the contract for heating the almshouse in that county. The contract is an important one, as both the main hospital building and the large asylum are to be heated. The company manufacture both steam and hot water heaters.

THE CONTRACT for the plumbing in the mansion of Charles Miller, at Nazareth, Pa., has been awarded to Fred. J. Rice of Bethlehem.

THE S. WILKS MFG. COMPANY, 113–123 Clinton street, Chicago, are to furnish one of the largest sized Wilks heaters, 42 x 48 inches, and a steel tank of 1500 gallons capacity, for the St. Benedict apartment building, Rush street and Chicago avenue. Also two large steel tanks and a 36 x 48 inch Wilks heater for I. C. Gifford's apartment building, Rhodes avenue and Thirty-third street. The firm have also received orders for four Wilks heaters from New York City, and two from San Francisco.

ARCHITECTS MURPHY & CAMP, Chicago, have designed for John Cashin a three story apartment house to be built on Prairie avenue, between Forty-fifth and Forty-sixth streets. It is to be heated by steam.

ARCHITECT ALFRED SMITH, Chicago, has planned for H. Wolf a two story, attic and basement residence, to be erected at 375 Ashland avenue. The interior will be finished in hardwood and heated by hot water.

ARCHITECT R C. BERLIN, Chicago, has designed for James A. Davidson a two-atory, attic and basement residence, to be built at 953 Jackson Boulevard. Furnace heat will be used.

ARCHITECT H. S. JAFFRAY, Chicago, has designed for W. R. Cowan a three-story apartment house, to be erected at Forest avenue, near Thirty-fifth street. It will be heated by means of a furnace.

ARCHITECT J. M. HOBKINS, Chicago, has made drawings for a suburban residence for O. L. Baily, to be erected at Oak Park, Ill. It will be frame on stone foundation, and provided with gas grates and combination heat.

ARCHITECTS FLANDERS & ZIMMERMAN, Chicago, have designed for J. Van Craenenbrock a three story apartment house, to be built at the corner of Fifty-fifth street and Monroe avenue. The interior will be divided into five stores and ten apartments, and will be heated by steam.

ARCHITECT J. H. MCELDORONEY, Chicago, has prepared plans and specifications for a fine residence to be built at Chicago Heights. Steam heat will be used.

ARCHITECT H. R. WILSON, Chicago, has designed for James M. Smith a three-story residence, to be built on Lexington avenue, near Fifty-first street. The interior will be finished in hard wood and heated by hot water.

KEHM & MERTZ, 289 East Kinzie street, Chicago, are to install a steam heating plant in the Woodlawn School, Lexington avenue, near Sixty-fourth street. The building contains 20 rooms and assembly hall.

TRADE REPORT.

The Iron Market.

In the Foundry Iron trade Philadelphia reports a good deal of activity, buyers having taken hold at the temptingly low offers made. Along the seaboard and in New England the unsettled condition of freights in Southern Iron leaves the situation in a mixed condition. It is pretty plainly intimated that very low rates are to rule and that prices of Pig Iron will be correspondingly cut. In the West buyers are hesitating about placing orders for Southern Iron, the feeling evidently prevailing that the recent concessions in freight rates have not yet reached the bottom.

Careful observers, while acknowledging that no early rise of any consequence is likely, do express the opinion that purchases at present prices are safe.

The renewal of troubles in the Connellsville coke region was a contingency which many in the trade have kept in view.

Pig Iron.—There has been a sharp cut in freight rates to interior New England points. Yet it is pretty plainly intimated by the railroad companies that special rates are simply a matter of negotiation. The result is that the market in New York and in New England is unsettled until it is definitely known what can be done. Sellers are practically giving away the whole of the advantage thus secured. Low prices have been made by Schuylkill Valley furnaces in New England. We note a sale of 1000 tons of Swedish Pig at private terms. We quote standard brands $12 50 @ $13.25 for No. 1; $11.75 @ $12.25 for No. 2; at tidewater. Southern Iron, same delivery, $12 @ $12.75 for No. 1; $11 @ $11.50 for No. 2; $10.75 @ $11.25 for No. 3; $11 @ $11.25 for No. 2 Soft, and $11.25 @ $11.50 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10.25 @ $10.75.

The volume of business in Pig Iron in the Philadelphia market has been considerably larger during the past few days, and while prices are lower holders feel very much encouraged by the liberal acceptances from leading consumers. Recently bids have been made and accepted for 500, 1000 and 3000 ton lots, with requests for options on additional quantities, all of which confirms the impression that business is improving. Besides this, other negotiations are fairly under way which promise to clean up all the odds and ends, or anything that is offered at attractive prices. Prices have been extremely low, lower than our inside quotations, but to get things moving holders were not inclined to stick at 25¢ a ton when the quantity was large enough to make it an object. There is an impression that very heavy cuts in freights are pending, and that, in fact, some of the sales just closed could not have been possible unless special arrangements of this kind had been made to enable the sellers to get out whole. What the exact figures are it is impossible to say, but they are understood to be much lower than ordinary quotations. General quotations for Philadelphia deliveries are about as follows, and from 25¢ to 40¢ less at interior points, such as Harrisburg and vicinity:

Standard No. 1 Foundry X	$12 50 @	$13.00
Standard No. 2 Foundry X	11.75 @	12 25
No. 2 Plain	10.75 @	11.00
No. 1 Soft	11.00 @	11.50
No. 2 Soft	10.50 @	10.75

Transactions for the week in the Chicago Pig Iron market have not been up to the average for the preceding four or five weeks. Local furnaces have taken the greater part of the business, such as it was. Southern sellers have done somewhat better in the country districts than in the city, but their sales have seldom exceeded 100-ton lots. The influence of the heavy reduction in freight rates from the South is felt unfavorably. Although the price of Northern as well as Southern Iron is now much lower than anything before known in this locality, yet buyers appear to have no confidence that values have actually touched bottom. They are disposed to wait for further developments and are apprehensive of changes in freight rates in other directions. Transactions are therefore confined to actual requirements in all kinds of Iron. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @	$15.50
Local Coke Foundry, No. 1	11.25 @	11.50
Local Coke Foundry, No. 2	10.50 @	11.00
Local Coke Foundry, No. 3	10.00 @	10 50
Local Scotch	11.50 @	11.75
Ohio Strong Softeners No. 1	13.00 @	14.00
Southern Silvery, No. 1	..... @	11.50
Southern Silvery, No. 2	..... @	11.00
Southern Coke, No. 2	10.00 @	10.35
Southern Coke, No. 3	9.75 @	10.00
Southern, No. 1, Soft	10.25 @	10.50
Southern, No. 2, Soft	9.75 @	10.00
Tennessee Charcoal, No. 1	15.00 @	15.50
Tennessee Charcoal, No. 2	14 50 @	15.00
Alabama Car Wheel	17.85 @	18.00
Jackson County Silvery	15.00 @	16.00
Other Ohio Silvery	13.00 @	13.50

In the Pittsburgh district some large sales of Bessemer Pig Iron have been negotiated. The short supply of Coke, owing to the Connellsville strike, is already having effect in the stoppage of furnaces. For the first time in some weeks there have been some good sales of Foundry Iron, but at the lowest prices touched. We are advised of a sale of 500 tons of No. 1 Foundry at a price equal to about $11, Pittsburgh, and one of 500 tons of No. 3 Foundry at a price equal to about $9 75, Pittsburgh. None of this Iron comes to Pittsburgh. Quotations are as follows:

No. 1 Foundry	$11 00 @	$11.25 Cash.
No. 2 Foundry	10.25 @	10.50 "
No. 3 Foundry	9.75 @	10.00 "

Metal Market.

Pig Tin.—Prices have moved about somewhat feverishly, but the extreme range covered was only about 30¢. The fluctuations were due in a great measure to the ups and downs of the London market. In other words, purely local conditions have had very little influence, if any, in shaping the course of values. The fact that London has a large stock on the spot and an unusual quantity afloat offsets all calculations of supplies, consumption, &c., on this side of the Atlantic, since it is uncertain when or to what extent Tin may be shipped from Europe to the American market. During the early part of the week under review some spot stock was sold at as low as 19.30¢. Subsequently 19.60¢ was paid in remote instances. Directly afterward 15 tons were sold on 'Change at 19.50¢ for prompt delivery, and 15 tons at 19 65¢ for June delivery. At the close the market softened somewhat under the influence of lower London quotations, but 19.50¢ net cash appeared to have been bottom rate for 5-ton lots, prompt delivery. Consumption is of about the same character and volume as it has been for some time past. It is still somewhat below the average for this season of the year. Small lots of Straits Pig from store are quoted at 21¢ @ 21¼¢ ℔ lb.

Copper.—The market for Ingot has remained quiet. At all events, none but very commonplace transactions have been reported, and the demand is represented as being quite as tame as it has been at any previous time during the past month or six weeks. Such as it is, however, the business passing is at practically former prices, and the market retains fairly steady tone despite the spiritless state of business. Lake Superior Ingot is quoted at 9⅛¢, prompt or future delivery. Electrolytic remains at 9¼¢ @ 9⅜¢, and over 9¢ @ 9⅛¢ is the exception on casting stock. For small retail quantities an advance of about 1¢ ℔ lb is the rule. The demand from consumers for both Ingot and Sheet Copper continues flat and disappointing. Exports from the United

States during the eight months ending February 28, as per statement of the Bureau of Statistics, were as follows:

	1894.	1893.
Ore—	Tons.	Tons.
To United Kingdom....	21,959	26,708
To Germany.....	1,016	78
To other Europe	none	none
Totals.....	22,975	26,786
	1894.	1893.
Ingots, bars and old—	Lbs.	Lbs.
To United Kingdom. ..	47,523,643	1,969,117
To Germany.....	18,160,862	2,260,306
To France.....	24,119,007	7,063,087
To other Europe.	50,601,917	6,605,578
To other countries.....	508,461	57,787
Totals.....	140,913,890	17,955,875

Pig Lead.—The destruction of the concentrator, ore houses and works of the Horn Silver Company, cutting off, as it did, a source of considerable supply and a free selling agency, caused heavy buying of the Metal. Nearly or quite 1500 tons changed hands at prices ranging from 3.37½¢ up to 3.45¢. Subsequently single carloads realized 3.47½¢. At this writing sellers are asking 3 45¢ @ 3.50¢. It is considered doubtful that the company will resume work within the next six months, and a firm market for Lead is therefore anticipated should the demand be normal. The Horn Silver mine production was about 600 tons ℔ month. A little more jobbing business was reported during the week, retail prices being firm at former quotations. Manufactured Lead remains dull.

Spelter.—Smelters who became tired of waiting for a better market dropped their prices suddenly a few days ago and the entire market became demoralized, with ordinary Western brands freely offered at 3.60¢ @ 3.62½¢, delivered here or at common point. As yet it does not appear that the lower cost has prompted freer buying by Eastern consumers and the market seems to be quite as flat as it was before the break took place. Since our last report 14 Western furnaces have closed down, making a total of 74 furnaces now idle, which were running at this time last year. It is reported that prices were forced down to compel these furnaces to close, and that lower prices are possible unless additional furnaces are added to the list of idle ones. The consumptive demand continues strictly moderate, and prices for small lots firm at 1¼¢ ℔ lb.

Antimony.—Dealings are moderate, and the market is barely steady, with 8¾¢ @ 9¢ quoted for Hallett's and 10¢ @ 10½¢ for Cookson's.

Nickel.—The market remains quiet, and 40¢ is still quoted as seller's price.

Tin Plates—In the earlier part of the week a very fair business was done in spot goods, chiefly in the shape of moderate sized lots for immediate delivery. Some few sales of large parcels, for both spot and future shipment, have also been made; the latter including some good sized orders for ordinary Bessemer Cokes for May and June delivery. The prices were, however, understood to be down to the level of the lowest current quotations. Forward shipments, nevertheless, do not command the interest usual at this time of the year, and the market is somewhat disappointing. The better movement was hardly maintained toward the latter part of the week. Prices are still rather uneven, with a slight leaning in buyers' favor, particularly for spot goods.

A special cable dispatch to *The Iron Age* from London, dated April 11, reports dullness in the British Tin Plate market. Small orders for Cokes are more plentiful at bottom rates, but the total is small. Sellers are cautious regarding forward contracts, owing to probability of stoppage of more works, possible labor troubles and belief that prices have reached lowest point. Stocks at Swansea about 287,000 boxes. Liverpool quotations for Plates were as follows:

IC Charcoal, Alloway grade.....	12/ @ 12/6
IC Bessemer Steel, Coke finish. ...	11/3 @ 11/6
IC Siemens " " "	11/6 @ 11/9
IC Coke, B. V. grade, 14 x 20.....	Nominal.
Charcoal Terne, Dean grade.....	10/3 @ 10/6

Sheet Iron—Black Iron is exceedingly dull. Except in the case of light Sheets for tinning puposes the jobbing trade in this material is at a standstill, and prices are demoralized. Although quotations are brought down to the lowest prices yet made, these can readily be shaded on desirable orders. Galvanized Iron is in slightly better shape, owing to some increase of movement in the building trades, and prices are more firmly maintained.

Chicago Report.

Scrap.—Old Material continues neglected. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap.....	$7.00	....

Trade Notes.

THE CLIMAX MFG. COMPANY, 415 Cuyahoga Building, Cleveland, Ohio, are directing attention to the Climax Flour Sifter of their manufacture. It is described as being operated with one hand, and various other advantages are alluded to.

THE TRADE will be interested in the announcement elsewhere of the Cortright Metal Roofing Company, Broad and Hamilton streets, Philadelphia, Pa., relating to galvanized steel shingles. The company inform us that heretofore they have made their goods only in tin plate and copper, but recognizing the fact that some people prefer galvanized goods, they have placed themselves in position to fill their wants.

CURTIS & CURTIS of Bridgeport, Conn., manufacturers of the Forbes Patent Die Stocks and all kinds of Pipe Working Tools and machinery, find that their labor saving machinery and tools are coming into such general use abroad that they have decided to send out one of their firm to consult with their agencies which are scattered throughout Europe and to look after their interests generally. Lewis B. Curtis expects to sail on May 16, and will be absent about three months. They inform us that they are running their works with a full force and are very busy with both foreign and domestic orders.

THE GEUDER & PAESCHKE MFG. COMPANY, Milwaukee, Wis., the well-known manufacturers of tin ware, make two very attractive articles in the line of Flue Stops—the Cream City, decorated and gold lacquered, and the G. & P., a handsomely lithographed design. Both styles are put up in paper boxes of one dozen each and in wooden boxes containing one gross.

THE RUE MFG. COMPANY, 116 North Ninth street, Philadelphia, Pa., publish their illustrated catalogue for 1894. The goods noted in the circular are the specialties of the manufacturers, which include the Little Giant, Fixed Nozzle and Unique Injectors; also Rue's Patent Boiler Washing and Testing Apparatus. The devices are illustrated and prices are given.

E. S. WHEELER & Co., New Haven, Conn., who have a large and particularly well equipped warehouse, announce that they are in specially good position to handle the business of close buyers of Tinners' and Plumbers' Supplies in any section of the country east of the Mississippi River, and to supply their distant trade from factory connections near to buyers. Their offering in our advertising columns this week is special figures in Cement Wash Trays.

AVERY STAMPING COMPANY, Cleveland, Ohio, advise us that Mervin S. Near of New York will represent their interests in the East, while A. E. Bronson of Cleveland will look after their welfare in the West.

CONDITION OF THE

Hardware Trade.

TRADE CONTINUES somewhat uneven in volume, there being complaint in regard to it in some sections, while from others reports indicate that business is on the whole improving, though not attaining to the volume of last year. The demand, however, is more uniform than it has been for some time, covering as it does a more general assortment and indicating a return of a healthful condition. There is still evidence of great caution on the part of merchants in purchasing, and it is apparent that business is still moving somewhat sluggishly. The cold, inclement weather which has prevailed in many parts of the country has had the effect of repressing business somewhat. We regret that we are not justified in referring to the state of the market in the matter of prices as showing signs of improvement. On the contrary, there has been a gradual settling in the prices of many goods for some time, manufacturers making all possible concessions with a view to inducing business. The fact that wages have been quite generally reduced and have still a downward tendency has its influence in the same direction, and the result has been that on many lines of staple and Shelf Hardware lower prices are now ruling than prevailed a few months ago. The large buyers for the most part get the benefit of these reduced quotations, but there is a disposition on the part of many manufacturers to sell retailers in fair lots at prices which approximate those at which they sell the jobbing trade. There is also among the jobbing houses a disposition to cut prices on many leading goods. As a consequence of these conditions the market as a whole is in an unsettled state with a downward tendency. This naturally induces especial care in buying goods, merchants with scarcely any exceptions limiting their purchases to their early requirements.

Advices from Chicago.—The first week in April has proved a disappointment to Shelf Hardware jobbers. The volume of business has fallen considerably below that of the corresponding period in March. It had been hoped that the spring demand would extend over the month of April, but the trade was evidently without sufficient strength to carry it much further than the first. The falling off extends to all classes of goods and appears to be equally distributed throughout the city and country trade. The city trade is of course affected by the building troubles. The Heavy Hardware jobbers report about the same condition of affairs in their branch. March was an exceedingly good month, but with the recurrence of cold weather the demand for Heavy Hardware immediately declined. Business is now dragging.

Notes on Prices.

Wire Nails.—The demand continues good, manufacturers being in receipt of some relatively large orders from jobbing houses and a good many orders of moderate size from the smaller trade. The aggregate of business is fair, and the mills are generally well supplied with orders. They are, however, desirous of securing business to keep their mills in operation for the next month or two. Competition is thus active and prices relatively low. Ninety-five cents at mill for round lots probably represents the market, some manufacturers being unwilling to make this price, however, except on especially large and attractive lots. There is, however, little difficulty in obtaining this figure on carload lots. Small lots from store in New York are held at $1.20 to $1.25.

Advices from Chicago.—Jobbers appear to have control of the business now coming up. The quotations they make on carloads are as low as manufacturers' prices. This causes the Wire Nail market to appear weaker than the facts would justify, although some decline has taken place in manufacturers' prices. The competition is, perhaps, greater for business in this city than in outside territory. Carload lots are quoted at $1.05, Chicago, while small lots from stock sell at $1.15 to $1.20.

Cut Nails.—The condition of the Cut Nail market is substantially the same as last week, with some unevenness in quotations, especially as the Eastern manufacturers are feeling to some extent the effect of Western competition. The price of Nails in car lots, delivered in New York, is 95 cents to $1 base. Small lots from store in New York are held at $1.10 to $1.15, with concessions on larger lots.

Advices from Chicago.—Little is now heard of the attempt of the Ohio River manufacturers to sell in this market. Local manufacturers report a fair trade for the week, but the volume of business is somewhat below the average of the previous weeks. Prospects are good for a fair trade with the Dominion of Canada in consequence of the reductions in the tariff. Inquiries are being received from numerous Canadian points. Factory prices are unchanged at $1 on 55-cent average. Small lots are selling from stock at $1.15.

Barb Wire.—The demand for Barb Wire continues good, though not so heavy as a few weeks ago. There is also evidence of some irregularity in prices, and some of the manufacturers are making concessions on the regular quotations on Four Point Galvanized, delivered, which are as follows: Pittsburgh, $2.15; Cleveland, $2.20; Cincinnati or Allentown, $2.25 ; Chicago or New York, $2.35.

Advices from Chicago.—Business has fallen off considerably within the past week or ten days. Buyers generally appear to have covered their wants, and the trade will now experience a period of dullness until stocks pass into consumers' hands. Manufacturers are also again taking control of the trade with consumers. Inquiries for both Plain and Barb Wire are being received from Canadian points, and some sales have already been made. Prices on Galvanized Barb Wire are unchanged at $2.25 to $2 30 for carload lots, and $2 35 to $2.40 for small lots from stock.

New Brass List.—A new list was adopted by the Brass manufacturers on April 9. The list as thus revised corrects many inequalities in the old list, and with the new discount makes an advance in some goods, especially in Brass Tubing, the new prices of which are considerably higher than the old. The list prices of some of the goods have been revised simply with a view to making them, with the rest of the list, subject to a uniform discount of 40 per cent.

Bright Wire Goods.—The market for Bright Wire goods, which continues an open one, has recently been characterized by active competition between the different manufacturers, with the result of inducing considerably lower quotations than have heretofore prevailed. As a result a discount of 90 and 20 per cent. is obtainable. There is, however, some inequality in the prices quoted by the manufacturers, and some of them refuse to meet the extreme prices of their competitors.

Cordage.—The Cordage market is in no better condition than last week and prices are a shade lower. Manila is now more frequently sold at 6 cents base than it was a week ago, but some of the manufacturers are still holding it at 6¼ cents, these figures applying to large lots. Sisal is quotably lower, being now readily obtainable at 4 cents base. New Zealand is held at the same figure, but with a moderate demand. Notwithstanding the low prices which are ruling the volume of business is only fair, as current quotations seem to have little effect in inducing the trade to purchase beyond their present requirements.

Suction Faucet.—Suction Faucet No. 64, put on the market by the Enterprise Mfg. Company of Philadelphia, is sold to the trade at $5 each, subject to a discount of 25 and 10 per cent.

Aluminum Chafing Dish.—Wohler Aluminum Company, 55 Jackson street, Chicago, are putting this article on the market. The Chafing Dishes are listed at $12 to $14, the discount to the trade being 50 per cent.

Glass.—The improved condition of the Glass market referred to in our report of last week continues, and manifests itself by a tendency toward stiffer prices. Prices that have ruled for some time have been far from satisfactory, and with the prospective spring demand manufacturers are hoping for some concerted action among them-

selves toward securing better prices. This movement is more pronounced throughout the western natural gas belt, though it is reported that some Pittsburgh manufacturers have withdrawn their former quotations. The New York Glass market is represented by the following quotations: In small quantities, single strength, 85 and 5 per cent. discount; double strength, 85 and 10 per cent. discount. In 1000-box lots, single strength, 85 and 10 per cent., and double strength, 85 and 10 and 10 per cent. discount. Pittsburgh quotations are reported as being 85 and 10 per cent. discount for single, and 85 and 15 per cent. discount for double strength Glass at factory. The demand for Plate Glass, it is understood, is improving, though no change has taken place in prevailing quotations, and are reported from Pittsburgh as being 70 and 10 and 5 per cent. discount.

Old Metals.—Business is rather better in Old Metals, although prices show little or no improvement. Old Iron and Steel meet with comparatively fair sale, but the quantities involved are unusually small. Wrought Scrap particularly is in better demand in the New York market. The following quotations represent dealers' purchasing price, New York or Jersey City delivery:

Heavy Copper	₩ lb		7¢
Light and Tinned Copper	₩ lb		6¢
Heavy Brass	₩ lb		5¢
Light Brass	₩ lb		4¢
Lead	₩ lb		3¢
Tea Lead	₩ lb		2½¢

Heavy Cast Scrap, ₩ gross ton		7.00 @	8.00
Stove Plate Scrap, ₩ gross ton		4.00 @	5.00
Burnt Iron, ₩ gross ton		3.50 @	4.00

Old Rags, Paper, &c.—The volume of business in these materials has been fairly large, although not up to the general average of last month. Prices are steady but continue low, the following quotations being about the rate offered in this market:

No. 1 White Rags	₩ lb	3¼ @	3½¢
No. 2 White Rags	₩ lb	2 @	2¼¢
Mixed Rags	₩ lb		¾¢
Blues and 3ds	₩ lb	1 @	1¼¢
Hard Sized White Shavings	₩ lb	2¼ @	2½¢

Hemp Twine	₩ lb	2 @	2¼¢
Manila Rope	₩ lb	2¼ @	2⅝¢
Jute Rope	₩ lb	1½ @	1¾¢
Mixed Rope	₩ lb	¾ @	⅞¢

Old Rubber.—The market for Old Rubber shows some improvement, but prices are somewhat irregular. The following quotations represent approximately those given by dealers in this city:

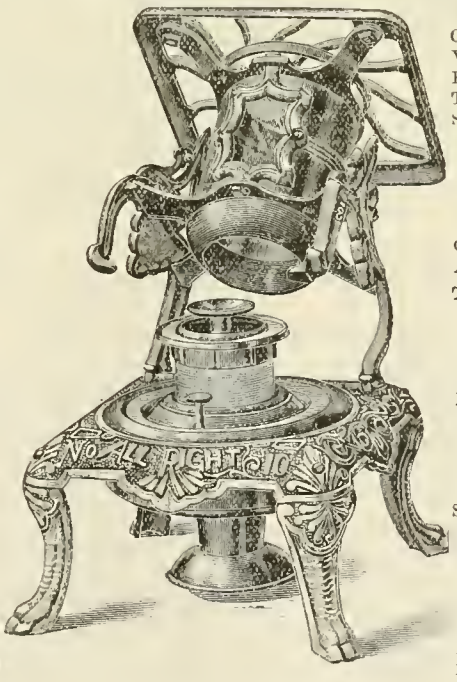
Car Springs, ton lots, ₩ lb		@	$0.03½
Rubber Shoes, carloads, delivered at factory, ₩ lb		@	.03½
Rubber shoes, less than carloads, ₩ lb		@	.03¾
Large Hose, ₩ ton		@	12.00
White Wringer Rolls, ₩ lb		@	.03¾
White Syringes, ₩ lb		@	.03¾

THE GILBERT & BENNETT MFG. COMPANY, 148 Lake street, Chicago, are now manufacturing Poultry Netting at their Chicago factory. It is made of wire galvanized before weaving. The company state that while they do not regard it equal in durability and strength to standard "G. & B." Netting galvanized after weaving, it is made of as good material, as perfectly woven and rolled up in the same manner as all other Netting of the same kind. The company are therefore prepared to furnish the trade with either kind of Netting, galvanized before weaving or galvanized after.

E. T. BARNUM, Detroit, Mich., issues a very extensive illustrated catalogue of his wire and iron goods. The pamphlet, which contains 120 pages, is profusely illustrated and shows a varied line of art and iron work. Settees, chairs and benches are followed by gates, netting, guards, &c. Later on attention is given to stable fittings, then come railings, fire escapes, stairways, grills, crestings, finials, weather vanes, &c.

The All Right Lamp Stove.

The Coldwater Oil Stove Company of Coldwater, Mich., are manufacturing a lamp stove of their own design, which is herewith illustrated. The cut shows the No. 10 stove, with the top thrown back in position for lighting or trimming the wick. This stove stands 14 inches high, the top is 8 inches square, the lamp is a central draft lamp of high power, and the oil tank is made entirely of drawn brass. The base and frame are of cast iron, fully nickeled. The No. 15 stove has a longer base, holding two lamps, and thus making it double the capacity of the No. 10. An oven is made by the company of suitable size for this stove which is capable of doing a considerable range of work. They have their own foundry and nickeling plant and make all parts of these stoves.



The All Right Lamp Stove.

BURT COLE has moved his tin shop to the store formerly used by J. B. Keasler as a storeroom, at Adrian, Mich.

A. LA ROCK is to continue the tin and plumbing business at Franklin, Vt., at the old stand of W. H. Lautman & Son, who have moved to East Highgate.

CANONSBURG IRON & STEEL COMPANY of Pittsburgh, Pa., with works at Canonsburg, Pa., started up their new tinning pots on March 22 for the manufacture of tin and terne plate. The plant has a capacity of 80 boxes per day.

It Is Reported—

Alabama.

That the Hardware firm of Luttrell & Fuller, BREWTON, has been succeeded by Luttrell, Fuller & Co. The only change made in the business was the admission to partnership of R. E. Mallett, who has for several years past been in the employ of J. Randolph Brown of Troy, and who is referred to as a Hardwareman of considerable ability and experience.

California.

That Z. C. Mathes has opened a new Hardware store in the Snyder Block, SAN DIEGO.

Florida.

That W. H. Parkin, formerly of Cleveland, Ohio, will soon open a new Hardware store at PALM BEACH, DADE COUNTY. Palm Beach is the terminus of the new Jacksonville, St. Augustine & Indian River Railroad. Mr. Parkin's store will be the only exclusive Hardware store at Palm Beach, which has grown largely during the last six months He expects to conduct both a wholesale and retail business.

Illinois.

That Hopkins Bros., CENTRAL PARK, have purchased the Hardware and Tinware stock of H. E. Rebmann. Mr. Rebmann contemplates taking a trip to California.

That the Hardware stock of Wadsworth & Matheson, JACKSONVILLE, was completely destroyed by fire on the 26th ult. The loss is estimated at $30,000.

That S. F. Yeager & Son of PEARL CITY have disposed of their Hardware stock to John Klapp and A. M. Schotz.

That S. O. Stillman, GALENA, has been succeeded in the Hardware business by Stillman & Stahl.

Indiana.

That J. W. Miller has purchased an interest in the Hardware store of F. V. B. Minnich, GOSHEN. The style of the firm will hereafter be the Minnich Hardware & Furniture Company.

Iowa.

That W. H. Sedam is a new Hardwareman at STANWOOD.

That Kunz & Fay's Hardware store, BELLEVUE, was burglarized on the 26th ult. Thirty dollars' worth of goods were taken by the thieves.

That Liebig & Sons, KALONA, have sold their Hardware store to Lucas, Rust & Smith of KINROSS.

Kansas.

That the Woodbine Hardware Company's store, at WOODBINE, was destroyed by fire on the 29th ult.

Maine.

That F. T. Dana, WISCASSET, dealer in Hardware and Cutlery, has removed to a new location in that place.

Massachusetts.

That the Stove stock of Folger & Reagan, GLOUCESTER, was damaged by fire on the 5th inst.

That Thurston, Hale & Co. have recently entered the Hardware business at ROCKPORT.

Michigan.

That the dynamite storehouse of the Ferguson Hardware Company, SAULT STE. MARIE, blew up on the 31st ult. It contained 5000 pounds of the explosive. The explosion shook the entire town and broke many windows.

That D. Leach, MINDEN CITY, is now conducting the Hardware business formerly carried on by Geo. W. Thayer & Co.

That J. C. Cozad has succeeded A. B. Kleaber in the Hardware business at WAYNE.

That L. S. Dickinson's Hardware store at FENNVILLE was recently entered by thieves, who took away about $60 worth of Knives, Razors and Revolvers.

Minnesota.

That H. A. Boyer of FOUNTAIN has purchased the Hardware and lumber business of John Johnson, and will take possession of it on May 1.

Missouri.

That the Hardware stock of H. A. Walcott, CARTHAGE, was damaged by fire to the extent of several thousand dollars on the 30th ult.

New York.

That John Lilley's Hardware store at BAINBRIDGE was burned out on the 2d inst. The loss was fully covered by insurance.

That Murphy & McEligott's Hardware store at CLYDE was slightly damaged by fire on the 3d inst.

That Leonard Jones of Remsen has entered the Hardware and Tin business at HINCKLEY.

That Frank Hall, Hardware merchant of PRATTSBURGH, has sold out to Flynn & Walker.

That Peter J. Kimmel has bought a half interest in the Hardware business of M. Kimmel & Son of COHOCTON.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

HELP WANTED.

STOVE SALESMAN in Massachusetts, Rhode Island, Connecticut, New York and Pennsylvania can make good side commission by addressing O. G. & D. H. Donaldson, Buffalo, N. Y. Apr. 14

A young man that understands tin and sheet iron business; one that can read and write a good hand and is capable of taking charge of store; please state wages wanted. "Capable," office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

An A 1 STOVE SALESMAN for New York City trade; state age, experience and salary wanted. "J. B.," office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

SALESMAN for a first-class line of stoves for Ohio, Illinois, Minnesota and Wisconsin. "N. H.," No. 414, office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

A first-class TINSMITH at once to work on milk coolers; one preferred with small capital. H. W. Gazley, Cortland, N. Y. Apr. 14

A RETINNER, with experience in retinning tinware, and capable of taking charge of a retinnery; steady job to capable man. Standard Stamping Company, Second and Chambers streets, St. Louis, Mo. Apr. 14

A competent PLUMBER; one used to country work preferred; to a man that is not afraid of doing a good day's work steady work and fair wages will be paid; state experience and wages expected. Burbank, Studd & Metze, Berlin, N. H. Apr. 14

TRAVELING SALESMEN, visiting the retail hardware trade, to handle our goods as a side line; no samples to carry; sales made from catalogue and small nickel model weighing 2 pounds or less; full information and catalogue sent on application. Lock Box 34, Pike, N. Y. Apr. 14

PLUMBER and TINNER for country shop; must understand his business; one with some knowledge of the hardware business preferred; steady job to the right man; immediately; state age, wages and experience; married or single. O. H. Tebay, Leechburg, Pa. Apr. 14

SALESMEN calling upon the gasoline stove, hardware or grocery trades, to handle our complete line of oil cans, tanks, &c., on commission; easy sellers, right prices and liberal commission. "Oil Cans," office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

A good boy between 16 and 18 years of age to learn the tinning and plumbing trades; one who will serve for three years; $50 a year, board and washing; good home for a good boy. A. M. Kreider, Lititz, Pa. Apr. 7

A good all round TINSMITH, with some knowledge of plumbing; temperate and industrious; to the right party a steady position is open; state wages expected. 545 Main street, Niagara Falls, N. Y. Apr. 7

By a tin plate and metal house, a first-class SALESMAN who thoroughly understands tin plates, sheet iron, brass and copper goods, to travel in the West. Address, with references, P. O. Box 1530, Philadelphia, Pa. Apr. 7

SITUATIONS WANTED.

By a good TIN, SHEET IRON and FURNACE WORKER; understands steam and hot water fitting and the combination steam and hot air work. Chas F. Snyder, 73 East Louisa street, West St. Paul, Minn. Apr. 14

By a young man 20 years of age, with three years' experience at plumbing and gas fitting; can wipe a good joint; some knowledge of tin, sheet iron and range work; city or country. F. V. Martin, Box 153, New Milford, Conn. Apr. 14

By a TIN and SHEET IRON WORKER, who is also a gas and hot water fitter; 15 years' experience at general jobbing; reference. J. Walden, New Rockford, N. D. Apr. 14

By a perfect TIN, SHEET IRON WORKER and ROOFER; steady position in or out of town. T. Greenberg, 64-66 Canal street, New York City. Apr. 14

By a practical TIN and SHEET IRON WORKER; some knowledge of furnace, range, heater work, roofing and general jobbing. "Tinsmith," 242 North Second street, Williamsburg, Brooklyn, N. Y. Apr. 14

By a PLUMBER; learnt trade in Philadelphia; plumbing, gas, jobbing or steam work, sanitary drainage, and house wiring on Edison system; age 23; honest, sober and willing to work; can furnish reference. Henry M. Wendel, 32 S. Wyoming street, Hazleton, Pa. Apr. 14

By a TINNER; four and a half years' experience; can do roofing, spouting, stove, pump and shop work; strictly temperate; best of references. A. F. Segerstrom, Forest City, Iowa. Apr. 14

By a first-class PLUMBER; city or country; 15 years' experience as an all around worker. J. M. Harrington, 140 Degraw street, Brooklyn, N. Y. Apr. 14

By a CORNICE and SKYLIGHT MAKER, as FOREMAN of a small shop or assistant cutter in a large shop; nine years' experience; 27 years of age; understands English and German. L. D. Retman, 111 Delancey street, New York City. Apr. 14

By a good TINSMITH, for in and outside work, used to country work, also general jobbing; willing to work in city or country. Address J. Cohen, 148 Delancey street, New York City. Apr. 14

By a practical MECHANIC and INVENTOR on tin and iron work, spinning and drawing press iron. E. Plancom, 863 Park avenue, Brooklyn, N. Y. Apr. 14

By a TINNER; can do roofing, bench and furnace work; 14 years' experience at trade; strictly temperate and reliable and not afraid of work; would like position where I could learn pipe fitting. "G. A. B.," 147 Cabot street, Lowell, Mass. Apr. 14

By a first-class PLUMBER; not particular as to locality. J. Reilly, 504 West Twenty-eighth street, New York City. Apr. 14

By a good TINNER; eight years' experience at inside and outside work, general jobbing and furnace work; some knowledge of clerking; can make up tinware; sober and reliable; good references. Wm. F. Gritzmacher, Faribault, Minn. Apr. 14

A married man desires a steady situation at moderate wages with a good firm as SLATE and TILE ROOFER; understands his trade thoroughly and is capable to do tin and iron roofing and all kinds of jobbing; good workman with best of references; reason for desiring a position—former employer retired from business. "Slate and Tile Roofer," office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

As BRASS MOLDER; well experienced on any class of work; location no object; an engineers' jobbing shop preferred. "W. B.," 36 Sampson street, Allegheny, Pa. Apr. 14

By a steady, sober and reliable TINNER; 15 years' experience on general work; reference furnished if required. "Tinner," 249 West Eleventh street, Anderson, Ind. Apr. 14

By a practical TINSMITH, ROOFER and GENERAL JOBBER; thoroughly experienced; city or country. Jacob Goodman, 99 Forsyth street, New York City. Apr. 14

In Wisconsin, Illinois or Iowa, by a good TINNER; 14 years' experience at all kinds of work; can speak English and German and clerk in store; married; strictly temperate; first-class references; two and one-half years with last employer. H. G. Habedank, Albany, Wis. Apr. 14

By a first-class high and low pressure STEAM and HOT WATER FITTER; can make working plans and solicit work; expert at hot water; lots of experience; no objection to traveling; best of references. "Success," No. 414, office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

FOREMANSHIP, by practical tin and sheet iron worker; can handle any number of men judiciously; best of references; sheet metal specialties preferred. C. Harvey, 251 Fourteenth street, Buffalo, N. Y. Apr. 14

As MANAGER or FOREMAN of stove works; 24 years' experience; understands the business in detail; thoroughly practical in mounting, polishing, plating and pattern fitting; has always handled men to the best advantage. "A. W. C.," care of Fred. W. Donnelly, 912 Carroll avenue, Chicago. Apr. 14

By a young man, 28 years of age, with five years' experience in the retail hardware and farm implement business; has natural talent for machinery; is sober and industrious; best of references. P. O. Box 65, Cordova, Md Apr. 14

By a first-class SKYLIGHT and CORNICE MAKER and CUTTER; can work from plans; willing to work at the bench or to take charge of shop; best of references; can speak English and German; willing to go on trial for a month; strictly sober and reliable. M. Grossman, 193 River street, Paterson, N. J. Apr. 14

As FOREMAN of stove mounting shop by a practical man; can handle any number of men; best of references. Geo. Balles, 163 Mackinaw street, Buffalo, N. Y. Apr. 14

A boy, 17 years old, with some knowledge of the plumbing trade, would like to learn it thoroughly. I. H. Singer, 222 Second street, New York City. Apr. 14

By a young man as TINSMITH; experienced in city and country work; position desired near New York City. Fred Waxman, 1208 First avenue, New York City. Apr. 14

A young man with two years' experience in the roofing, range and furnace trade would like to get a position as apprentice; good reference; will work anywhere in the United States. M. J. Walsh, 324 East Fortieth street, New York City. Apr. 14

A steady position by a competent STEAM FITTER and GENERAL JOBBER; one that has a good knowledge of plumbing and fully up in pump work; eight years' experience; not afraid to do a day's work; now employed in Boston, but wants a change. T. Frank Clark, 2 Trenton street, Charlestown, Mass. Apr. 14

By a first-class PLUMBER, city or country. C. J Smallen, 305 West Thirteenth street, New York City. Apr. 14

By a graduate of the plumbing department of the New York Trade School where he could be under instructions by May 1; no objections to a distant locality; best of references. "W. H. V.," Box 35, East Hampton, L. I., N. Y. Apr. 14

By a TINSMITH of 20 years' experience at inside and outside work; general jobbing, furnace, steam, hot water and plumbing; references; steady job by the year. "T.," Box 414, office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 14

By a first-class TINSMITH, on or about April 15; 22 years' experience; both inside and outside workman; understands furnace and range work in all its branches; can do iron pipe work and pump work. "Tinner," Long Branch City, N. J. Apr. 14

By a TIN and SHEET IRON WORKER; 12 years' experience; understands all outside work, gutters, roofing, furnace, stove, range and fireplace heater work and general jobbing; city or country. L. Saltman, 137 New street, Philadelphia, Pa. Apr. 14

Steady work, by a young man used to all kinds of tin, sheet iron and furnace work; some knowledge of lead and iron pipe work; sober and good workman. T. H. Atkinson, Virginia P. O., Ontario, Canada. Apr. 14

By a young man, 21 years of age, with seven years' experience at PLUMBING and GAS FITTING; country preferred. Henry N. Will, 18 Dodworth street, Brooklyn, N. Y. Apr. 14

By a first-class PLUMBER; city or country. Joseph Smollen, 533 West Thirty-ninth street, New York City. Apr. 14

By a PLUMBER and GAS FITTER; strictly sober; wages moderate. Henry W. Bauer, Paris, Ky. Apr. 14

By a first-class CORNICE MAKER; ten years' experience; understands all kinds of work; city or country. R. Schatz, 603 Poplar street, Philadelphia, Pa. Apr. 14

By a TINSMITH, inside and outside worker; understands furnace, range and heater work, also roofing and plumbing; married man; 25 years' experience; good references. Lock Box 102, Sterling, Kan. Apr. 14

By a practical TINSMITH, German, steady, for all kinds of jobbing, roofing, furnace, range and heater work; understands also plumbing and gas fitting. Printing Office, 521 Sixth street, New York City. Apr. 14

By an ELECTRO PLATER of long experience in silver, nickel and brass; best of references; wages moderate. H. M. Ostrander, Albany, N. Y. Apr. 14

With good firm doing hot air heating; have had several years' experience; am capable of estimating work from plans and handling men; would prefer job with firm doing both hot air and hot water work; will not go East; would accept position with firm as traveling salesman for good hot air furnace. "N. H. L.," Station A, Pittsburgh, Pa. Apr. 14

By a PUMP MAKER on first-class work only; best of references. Fred. Kennebecker, Middletown, Conn. Apr. 14

By a thoroughly experienced MANAGER with long foundry experience; successful in establishing and running foundry agencies, wholesale and jobbing houses; bookkeeper and salesman. "Successful," office of *The Metal Worker*, 96-102 Reade street, New York City. Apr. 7

Modern Plumbing.

To the interested observer a growing change in plumbing work can be seen. The skillfully executed and beautiful lead work that has been the pride of the plumber since the craft first came into existence fails to hold the people loyal to it. As the handsome white porcelain lavatory and the earthware water closets have supplanted the appliances of a few years back, so have the nickel plated traps and pipes grown in favor. The use of wrought iron for both drainage and service pipes has made rapid advance recently. A plumber of the old school who has never left the vanguard recently said that in his highest class work he frequently used less than 100 pounds of lead on jobs where formerly tons would have been used. Another plumber who seeks only contracts where the very best work will be demanded stated that what he considered the finest job of plumbing in the United States did not have a pound of lead used on it. And so the practice of the trade is changing, and the plumber, who as his name implies was originally a worker in lead, is becoming more and more a worker in iron and other metals. Or to speak more accurately, he is not so much a worker in metals as a worker in metallic goods; a domestic engineer whose business it is to lay out a system of plumbing and install the apparatus with their proper connections.

The Franklin Trade School.

It is announced that the trustees of the Franklin Fund in the city of Boston have definitely decided that the sum available—now amounting to about $300,000—shall be devoted to the establishment of a trade school, after the pattern of that in New York. A committee of the trustees, accompanied by the City Architect, are about to visit the schools of this nature now in operation in New York, Brooklyn, Philadelphia and other places, in order to obtain the necessary practical information as to buildings, equipment and methods. Their intention, it is said, is to have the plans drawn and the work of building begun at the earliest practicable moment. When erected and equipped the institution must, according to the terms of Franklin's will, be transferred to the city, which will be responsible for its permanent maintenance.

The Tin Plate Situation.

One of the marked features of the present tin plate situation, induced by tariff uncertainty, is the large and increasing proportion of tin plates held in bond at New York, as shown by the returns for March 31, 1894. The value of such material in bond at that date was nearly double that of tin plate in bond at the end of February. The quantity thus held at the end of March was 4300 tons, compared with 2376 tons on the same date in 1893, although the importation for the first three months of this year was much below that of the corresponding period in 1893. The reason is not far to seek. Importers are not inclined to pay the existing duty on any large amount of stock, which may be left on their hands at a considerably reduced value in the event of a reduction in the tariff. Consequently they are content to withdraw from bond only such goods as they can readily dispose of at present prices. Meanwhile shipments from the other side are not increasing in any material degree, and free stocks in dealers' hands have been shrinking week by week and are now of unprecedentedly small proportions. Should a sudden expansion in the demand develop for any reason, such as an unforeseen access of energy on the part of the Washington lawmakers, resulting in the summary passage of the new tariff law, importers and jobbers of tin plates would be in a very poor position to meet the same. The English exports of tin plates to the United States in tons for the first three months in each of the past five years were as follows: 1894, 48,616; 1893, 75,022; 1892, 62,611; 1891, 98,909; 1890, 59,197.

A novel and effective method adapted by the Philadelphia branch of the Women's National Health Protective Association for abating nuisances is photography. In a certain quarter of the Quaker City the refuse from a stable and from an adjoining cigar factory had long been piled together in a heap that was a nuisance and a menace to the health of all who resided in the neighborhood. A member of the association had the objectionable mass photographed, and sent a blue print of it, with her complaint, to the Board of Health. The nuisance was promptly abated.

An Open Letter on Profit Sharing.

The Association for the Promotion of Profit Sharing has issued the following letter. It is signed by Carroll D. Wright, Washington, president; Francis A. Walker, Boston, N. O Nelson, St. Louis, vice-presidents; N. P. Gilman, Boston, secretary; R Fulton Cutting, New York, Alfred Dolge, New York, R. R. Bowker, New York, Henry R. Towne, Stamford, Conn., George A. Chace, Fall River, Mass., directors:

In anticipation of a revival of business and the consequent reopening of many mills and factories, which now seems probable, we would invite your attention to the importance of introducing some form of profit sharing as a feature of your industrial relationships. The method of paying a dividend to the workman out of profits as they are realized annually has been approved by most of the economists of Europe and America as thoroughly practical, and advantageous to both the employer and the employed. We will mention a few characteristics which should commend it to your careful attention.

Profit sharing can be adopted by an employer without risk of loss, inasmuch as he assumes under it no obligations except such as are to be discharged from profits actually made. His prerogatives as manager and his rights as proprietor are not curtailed. Profit sharing would establish a more friendly relationship of common interest between working people and the employer. This would be the surest pledge of industrial peace and the firmest support in times of commercial distress.

The employee, responding to such an advance by the employer, can increase the quantity and improve the quality of the product under a deeper feeling of personal interest. By his diligence, care and economy, he can actually create an additional profit, which is to be used in supplementing regular wages. Profit sharing includes the payment of the best wages current, and promises a bonus beyond this, which, experience shows, the interested workman can invariably produce in good times.

Profit sharing as a principle may be applied in a large variety of ways, and it can be readily adapted to the great majority of productive and distributive enterprises. We invite applications for full information concerning the history and the results of the system as it is now in operation in many establishments, small and large, in Europe and the United States. The address of the secretary of our association is 25 Beacon street, Boston, Mass.

According to the reports gathered by the *Journal of Commerce*, the fire losses of the United States and Canada for the month of March show a gratifying decrease. They were in all $9,147,100, or over $2,000,000 less than those of February, and considerably below those of the corresponding month of 1892 and 1893.

THE LETTER BOX.

Some Electrical Questions.

From C. W. S., *Brooklyn, N. Y.*—Referring to those talks on electricity that appeared lately in *The Metal Worker*, there are some further points concerning which I seek for information and trust that you will be able to supply my wants.

1. Is there any difference between an induction and spark coil?
2. What kind of work are storage batteries most suited to?
3. Why are zincs in batteries amalgamated?
4. How can you tell when the battery needs recharging?
5. Does the carbon part of battery ever need renewing?
6. Is the battery wire on ordinary work heavier than the return wire? Also what sizes of wires are used for different kinds of work?
7. Is there a rule to tell the number of batteries required on different kinds of work?

Answer.—We have submitted the above questions to the author of the serial article on "Domestic Electrical Work," and he furnishes us the following answers:

1. Yes, the induction coil consists of a primary coil of coarse wire, surrounded by a secondary coil of very fine wire, and provided with an interrupter to break the primary circuit in rapid succession. The passage of a current through the primary coil induces currents having very high electromotive force in the secondary coil and will throw a spark across considerable space. This coil is used, for instance, to ignite blasting cartridges or for multiple gas lighting. The spark coil simply consists of what constitutes the primary part of an induction coil and is used for ordinary electric gas lighting.

2. Storage batteries are used for electric lighting and running motors. They are not capable of generating electrical energy, but are used simply to receive a current from some primary source and store it for use at a future time.

3. The amalgamation of zincs simply means coating their surface with mercury to protect the naked surface from what is known as local action. This wasteful action is the result of hard or soft spots in the zinc, and the waste is caused by little local currents being set up between them. By amalgamating the surface with mercury all these spots are connected together, thus preventing the formation of local currents.

4. The first intimation that a battery needed attention would be the weakening of the current or a milky appearance of the solution. If the latter, put in a new solution; if only a weakening of the current, examine the zinc, and if badly corroded renew it, or if in fairly good condition, it may only need a good scraping. If this does not improve the battery, renew the solution and zinc.

5. It does not.

6. In cases where but one battery and one return wire are used both may be of the same size, but in cases like hotel annunciator work where the battery wire may be called upon to furnish current to ring a number of bells at the same time, it is obvious that this wire should be larger than the return wires. It is customary to use No. 16 for battery and No. 18 for return wires in this class of work. In ordinary bell and gas lighting work No. 18 is used for both.

7. As a general rule the best results are obtained by connecting the battery in such a manner that the external and internal resistance are equal. In some cases, however, this will not be possible, and a combination must be chosen which will come nearest to these conditions. As, for instance, connecting the cells in series, multiple arc, or multiple series. Where the external resistance is great the battery should be connected in series in order to secure a great electromotive force; when the external resistance is small, connect the battery in multiple arc. If the total internal resistance of a battery connected in series is greater than the external resistance, the following combination should be adopted: Multiply the number of cells by the external resistance, divide this by the resistance of a single cell and take the square root of this quotient; this will give the number of cells to be connected in series.

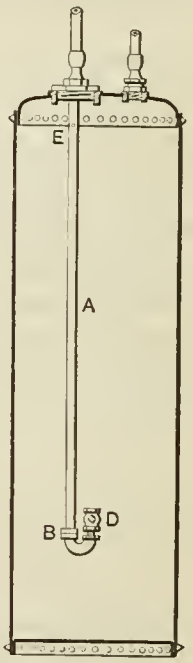
Wants a Rust Preventive.

From A. L. H., *Woburn, Mass.*—I would like a receipt for making some kind of a blacking to keep parlor stoves from rusting when they are stored for the summer. Can *The Metal Worker*, or some of its readers, supply it?

Answer.—Protection for cast iron stoves has been generally considered unnecessary, but for sheet iron stoves satisfaction has attended the use of a coating made of common beeswax dissolved in deodorized benzine. Just enough of the wax should be used to make a very light film on the iron to protect it from the condensation of the moisture in the air and not enough to interfere with blacking the stoves in the fall. It should be applied with a soft varnish brush. It must be kept in a tight vessel to prevent evaporation.

Safety Device for Boilers.

From H. W. W., *New York.*—I send a sketch which shows my idea for the prevention of accidents to kitchen boilers. The cold water pipe A has a short return bend on the lower end connected by a socket at B. The opening at the top of the boiler for the cold water pipe should be much larger than usual, to allow the bend to be inserted, and should be stopped by a reducing plug. On the return bend at D a check valve is placed and a hole is made in the supply pipe at E. This arrangement practically does away with



Safety Device for Boilers.

the expansion pipe which carries off so much heat and will also prevent explosions. When the pressure rises it will back through the hole at E into the main. The check valve will prevent the water being syphoned out of the boiler and steam can escape through the hole at E. I shall be glad to hear what the readers think of my arrangement.

Liability for Loans to Salesmen.

From E. M. W., *New York.*—Please publish your opinion as to the liability of a concern for money advanced to its representative. For illustration, an *attaché* of Sheet, Iron & Co. tells me he missed his remittance and asked the loan of funds until he shall receive the same. Do you consider Sheet, Iron & Co. liable for this?

Answer.—Our opinion is that "Sheet, Iron & Co." are not liable for the amount of the loan advanced to their representative. The power of borrowing money on the credit of an employer

for the personal benefit of an employee does not generally exist. And the fact that the money is borrowed for traveling or necessary expenses connected with the business of the employer makes no difference. It would be unwise and unsafe business policy to give a traveling representative a general power to bind his employer in this way. He might have received his remittance and lost it or gambled it away, and it would be a great hardship to compel his employer to pay the amount over again. The opportunities for fraud and collusion are infinite. If any such general liability obtained it would be easy to mulct the employer for a considerable sum. A salesman who feared he was about to be discharged could realize a very handsome amount by resorting to this method of involving his concern. A dishonest representative of a large house could in a single city apply to dozens of business men with whom his firm had dealings and obtain loans on the plea of "missing his remittance," and if the law sanctioned such a transaction his employers would be heavy losers in case the scheme was systematically worked. And it would not be difficult to do it. If the men applied to felt and knew that the law would compel the employer to make good the loan they would not hesitate if the house represented was a reputable and solvent concern. This is self evident. But it is a well-known fact that such advances are not made freely by business men to traveling salesmen. They are only made where there is a long acquaintance with the representative or where there is a feeling of personal trust in the salesman himself. Of course these loans are very frequent and common, but when they are made they are based upon the considerations mentioned. A business man would hesitate where such an application was made by a new and unknown salesman or one in whom he had lost confidence. Of course the lender has this security. He feels that his custom is valuable perhaps to the house represented by the borrower, and a threat of placing that custom elsewhere might and in many cases very likely would result in forcing the employer to sacrifice the amount of the advance rather than to lose his trade. But these are considerations of business policy and not of strict right. The law is clear, in our opinion. The loan is made to the salesman and he only is liable. His employers cannot be held. This is not merely an opinion. It has been so decided by the courts of New York in actual litigation, and we do not doubt that the same legal reasoning would be followed everywhere. There may be an exception in cases where the employer has permitted such loans to be made and has ratified them and made them good. This might create a custom with a particular concern on which they might have the right to rely. But these cases would be rare and the liability more or less doubtful even then. Of course, an express authority to the salesman to borrow money for his expenses would without question bind his firm. It would, however, be hard to prove, if the authority was denied on the actual trial of a case. We have considered the case of a traveling salesman, to which we presume our correspondent refers. He uses the words "representative" and "*attaché*." We can easily conceive that if the "representative" or "*attaché*" were the president or treasurer or other officer or the manager of the company or a member of a firm, the rule would be different. Such responsible officers and agents would in most cases have a right to make their principal liable for such loans contracted for the benefit of the principal and necessary for the transaction of the principal's business. But even then the principal would not usually be liable for loans made for the personal benefit of the borrower. It might raise a nice question, and if the amount was large the lender would inherit a lawsuit, the issue of which would be by no means certain.

Chimney Flues and Their Drafts.

From CRITIC, *New York.*—It is an axiom that two things exactly alike will act identically the same when the conditions are the same. This is true of the flues of a residence as of anything else, although many builders will dispute it. If built alike and situated and used in the same way, the results will be equally good in each one.

There are, however, many slight changes or oversights that may, unknown or unnoticed by the builder, serve as a complete ruination of the draft of a flue. For example, we have six houses, each with a single chimney and a single flue, the latter, however, with four openings—two on each floor. In four of the houses the draft is good and no trouble from soot is experienced, while in two soot has accumulated rapidly. In the first four direct draft stoves are used in each four rooms having openings to the flues. In the unfortunate two only two stoves with return drafts are used. The brick work is the same in all, so, evidently, the heating apparatus or its arrangement is at fault.

First examine the apparatus. Any check in the passage of the smoke and gas from any heating apparatus means a loss of heat to the smoke, and (here is the valuable point) is, of course, retained in the room or building. The loss of heat to the smoke and gas means an increase in weight. It is not so light as when hot, and there is less tendency for it to rise. This makes the draft sluggish, and the small particles of carbon and ash that give smoke its color are carried with greater difficulty and are to a much greater extent left in the flue as soot. This is one reason. Next, examine the arrangement of the openings to the flue. There are four in all the chimneys. And here it will not be amiss to say that never should there be a flue with more than one fire place, and it is best never to have more than one opening of any kind below the roof. In the "good" flues each opening is filled with an inflow of warm air and smoke, and each helps the draft of the others. In the "poor" flues two openings admit fairly warm smoke, while the others leak in cold or cool air, the latter not only not helping the draft but seriously injuring the movement by chilling the air that otherwise would rise because it was warm. Thus, where at first glance the conditions are the same and results dissimilar, we find on examination that the things themselves are quite different.

Leaving the example taken, it may be suggested that a flue on the inside of a residence will burn better than one in an outer wall, and, quite as important, will give a far larger amount of heat to the building. If a flue is placed on the outside it should have 8 inches of brick work on the exposed side, all the way to the cornice. The interior walls of a flue should not be over 4 inches, as here the escape of heat from the smoke means the gain of warmth in the house. Tight brick work is absolutely necessary for a good draft, and it is better, if the surface is plastered, to coat the outside rather than the inside. A flue circular in cross section is the best, and the shape nearest approaching this is most desirable. A square is, therefore, the best shape for ordinary brick work, being 8 x 8 inches for the usual fire place or range. Triangular flues are the worst a builder can conveniently make. They have over four-fifths the wall area, which means proportional loss of heat and proportional loss of speed, while their cross area is only half. Besides, the sharp angles offer additional friction, and so the resistance is even more than that of the square flue, while the volume is only half.

The man who builds a straight flue of good brick work above the top of the house and who has but a single opening to each flue need have no fear as to the results, provided his neighbors do not interfere.

Can Top Wanted.

From J. G. BLAKELY & CO., *Grand Rapids, Mich.*—Can any of your readers inform us who manufactures a can screw top, in which when the top is pressed down with the thumb the oil flows into the lamp and when the thumb is released the oil ceases to flow? These tops are on the market and are manufactured by some one in the United States, we think.

Hanging Gutters.

The following entertaining letter comes from a Montana correspondent who was asked to give his method of hanging long gutters:

If there is anything that I know less about than another it is gutter hanging. Have done a few jobs, however, and always had good luck. Never had a job blow down. Always used the old tin strips. The proposition you suggest of a barn 80 feet long would depend some on circumstances, lay of ground for drainage and how many down spouts we could work on the "old man." There are very few buildings in this country with gutters outside the towns; that is, the business houses with flat roofs, and they would be better without them as they fill up with ice and back up the water 6 inches deep at times.

The Indiana Board of Health has ordered the vaccination of all tramps found in the State.

The Vermont Slate Industry.

In a recent issue the Troy *Times* gave a very interesting description of the typical Vermont village of Fair Haven, illustrated by excellent engravings. From this article we extract the following account of the important slate quarrying industry for which that locality is famous:

The principal industry of Fair Haven is the quarrying and working of slate, the town being the slate center of Vermont, the State ranking second to Pennsylvania in the quantity of slate produced and second to none in the quality. In the hills about the town are some of the choicest veins of slate in the world, and it is estimated that no community has a larger number of quarries within its borders. Everywhere is seen the impress of quarrying. Derricks and lofty lifting cranes are almost everywhere noticed. Nearly all colors of slate are quarried, the principal being green, reddish brown, chocolate, "slate," mottled, bright red and bluish gray. The product is worked into every conceivable article for which slate may be used. Roofing and tiling slate are most produced, but slate for marbleizing and conversion into mantels, billiard beds, slabs, tanks and a score of other uses is also quarried.

The quarrying of slate in Western Vermont was commenced in 1839 by Alanson Allen and Caleb B. Ranney. The first quarries were for securing school slates, but the product did not meet the requirements for this use, being too hard, and in 1847 the first slate for roofing purposes was quarried. This is said to have been used on a house at Whitehall. The business continued to develop, until now it is a leading industry of Vermont and New England. Among the pioneers in the marbleizing of slate were Ryland Hanger and James Coulman, the latter being a member of the present firm of Coulman & Wescott. Mr. Coulman first began marbleizing slate in 1859 and has almost continuously been engaged in the business until the present time. Coulman & Wescott do a large business, the firm being formed in 1881. The firm employ about 50 men when operating in full, the wares including nearly every article into which slate is converted. Both members of the firm are practical slate workers. The firm own a quarry which produces a superior quality of green slate. Mr. Coulman is, perhaps, the oldest manufacturer still actively engaged in the slate business in the country.

Another old and influential firm are the Hazard Slate Company, established originally in 1852, when the manufacture of slate was instituted. They are pioneers in the slate trade. For several years prior to the establishment of the firm in Fair Haven S. L. Hazard, secretary and treasurer and general manager, was connected with a similar enterprise at West Castleton. The plant is in Fair Haven, and is one of the largest and most fully equipped in the village. The company own an extensive quarry and manufacture nearly every variety of mill slate goods. Mr. Hazard is a manufacturer of large experience, and holds a high position among the slate manufacturers of the State. W. F. Parker is president of the company. In addition to his connection with the Hazard Slate Company Mr. Hazard is the proprietor of the Lake Shore Slate Company of West Castleton. He brings many years of active experience into every enterprise with which he is connected, and is a power in all important slate transactions.

No concern of Fair Haven has a more extensive business and acquaintance than the Fair Haven Marble & Marbleized Slate Company, who beyond question are entitled to a place at the head of the slate industry. The house has a history dating since 1859, when it was established as Hanger & Coulman. The present designation dates from 1866, when the company were organized. The company own valuable quarries covering 22 acres, and the works along the Castleton River embrace two large factories, covering 2 acres. There are large yards for storage purposes, and the mills are equipped with the most nearly perfect appliances used in slate manufacture. Water and steam are both used to operate the works. The company manufacture everything made from slate. The products are both marbleized and unmarbleized, every article being of superior design and workmanship. The company have recently brought out imitations of most of the modern decorative marbles, such as Mexican onyx, Numidian onyx and several other varieties equally attractive. These are produced in marvelously close imitation of the most rare and costly marbles. The firm are also introducing a line of beautiful and artistic church altars. The firm have the contract for the wainscoting of the church of St. Paul the Apostle, on Fifty-ninth street, New York City, and will also place an altar in the church. Charles R. Allen is president of the company, G. H. Shinville is secretary and treasurer, and E. L Allen is general manager. E. L Allen is a native of Hartford, N. Y. He was a representative from Fair Haven in the State Legislature in 1880, and in 1890 was a candidate for Governor of the State on the Prohibition ticket. All the gentlemen composing the company are exceptionally talented business men.

The Valley Slate Company are another important concern, having been established in 1883 as successors to the long continued business of R. E. Lloyd & Co. R. E. Lloyd, the treasurer, and virtually the proprietor of the business, was one of the founders of the firm of Lloyd, Williams & Co., and is one of the foremost men in the slate industry in Vermont. The quality of the slate produced by the company's quarries is known as unfading green, and has a large sale in all parts of the country. Mr. Lloyd is also a member of the firm of Lloyd & Jones. This latter firm operate a quarry adjoining the quarry of the Valley Slate Company. Both quarries are 3 miles south of the village of Fair Haven, and about 35 men are employed. Mr. Lloyd is engaged in the erection of a block on Main street, Fair Haven, to replace the block burned in January, 1893. The new block is 90 x 25½ feet and three stories in hight. The block will be finished in the spring.

Prominently representative among the slate quarries of Vermont is that of S. Allen & Co. The business was founded in 1868 by S. Allen, and has always enjoyed confidence and patronage of a most substantial nature. The works are near the depot, and combine a mill, with dimensions of 100 x 50 feet, and an office and yards. About 30 men are employed. The company manufacture nearly every variety of slate products, the wares being of first quality. R. C. Colburn is associated with Mr. Allen in the company. Both are experienced slatemen.

The Riverside Slate Company, manufacturers of milled slate stock, are another prominent firm. The company include A. H. Merriam, president; B. Merriam, treasurer, and W. K. Merriam, secretary. The works are near the depot. The company manufacture every variety of slate products except roofing slate, and are recognized as one of the substantial firms of the town.

Maley Brothers, manufacturers of marbleized slate mantels, are acquiring a good reputation as dealers of business integrity and promise. The firm are composed of J. Maley and M. K. Maley, who are rising men. They employ about 15 men, and the trade is constantly increasing.

Griffith, Owen & Co., slate manufacturers, whose works are known as the Scotch Hill Slate Works, are prominent dealers. The firm's quarry is about 2 miles from the village of Fair Haven, where is a mill 50 x 100 feet in size, which has four circular saws to prepare slate for marbleizing. The members of the firm are natives of Wales, and they manufacture a most attractive line of mantels and other marbleized products, all of which command the best prices.

One of the best equipped quarries in Western Vermont is the Eureka Quarry, about three miles south of the village. The quarries give employment to about 125 men. A. Tuttle, who is one of the promoters of the plan for adapting the power of the Castleton River, through the dam at Carver's Falls, is one of the proprietors of the quarries. He is one of the best informed quarrymen in the State. The products of his quarries are used in roofing, and find the greatest sale, shipments being made to London, Australia and Mexico. The shade of the slate is attractive and much sought.

Another old slate business in the vicinity is that of the Billings Slate & Marble Company, whose marble slate mill is at Hydeville, and whose quarries are near that place. The business was organized in 1854 and reorganized in 1876. C. W. Billings of Troy is president, and C. W. Tennant treasurer and general manager. The company have a capital of $50,000 and employ about 30 men. The company manufacture slate mantels in all varieties for architectural uses. The mill secures power from Lake Bomoseen. Mr. Billings has long been identified with the slate industry, and is a capable business man. Mr. Tennant, upon whom has devolved the immediate supervision of the works, is familiar with every detail of the manufacture and sale of slate products. He is a former resident of Troy, N. Y.

Near the above works are the plants of R Hanger, who makes a variety of products, and Bolger Brothers, who operate mills and quarries.

The Foundry Slate Company and McDonough & O'Day, other firms in this locality, produce slate mantels.

E. D. Humphrey quarries purple roofing of a superior quality, and Williams, Pierce & Hughes quarry purple slate for milling purposes, both firms having good veins and producing desirable material.

Jacob Warner, whose works are in Fair Haven, near the depot, established his business about ten years ago. He manufactures marble and granite products.

William H. Pelkey, formerly Pelkey Brothers, conducts electric slate works and a foundry for castings.

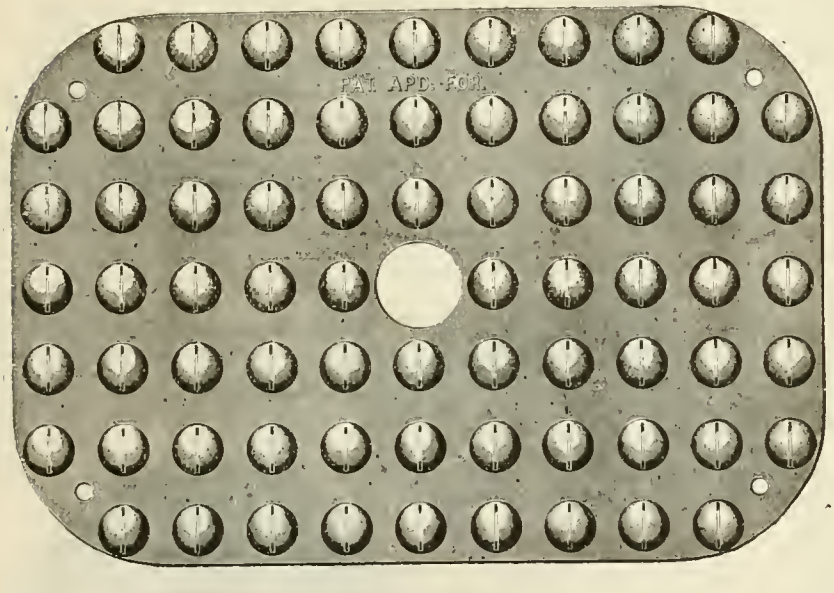
The William E. Lloyd Slate Company have some of the most extensive slate quarries in Fair Haven. The quarries are below the Eureka Quarries, and produce both purple and green slate. About 100 men are employed.

The quarries have a large capacity and are thoroughly worked. Mr. Lloyd has been continuously engaged in quarrying slate since 1865. His quarries produce roofing slate. He is successor to Lloyd, Owens & Co., his partners in that firm having been his brother, R. E. Lloyd, and Owen Owens. Mr. Lloyd has his son, William H. Lloyd, associated with him in the present enterprise.

Other slate manufacturers of Fair Haven are Minogue & Greer, H. H. Matthews, Robert Jones & Co, William Francis & Co., Roberts & Owen, Bennett & Felt, Minogue & Durick, James McNamara, St. Louis & Young and the Bonville Slate Company, all of whom do a good business during the season of activity in the slate industry.

A New Vapor Stove Burner.

The Michigan Vapor Stove Company of Grand Rapids, Mich., are using a new burner on their stoves, which is herewith illustrated. It is styled a "jet cone" burner. Each aperture as shown furnishes a jet of flame. The burner



A New Vapor Stove Burner.

shown is used on their 60 and 61 step stoves and has 72 jets. Round burners of the same description are used for the cooking holes. The 7-inch burner has 44 jets and the 5-inch burner has 21 jets. The company manufacture a full line of generator stoves, including step stoves, square tops, high juniors and juniors with single generators or individual burners.

The Naval Board that has been investigating the feasibility of converting the whaleback type of vessel into an auxiliary cruiser for war purposes has reported to the Department that these vessels are unsuited to the purposes of warfare on account of the impossibility of mounting heavy ordnance on board of them. The inventor and builder of the whaleback ships believed that it was possible to convert them into formidable coast defense vessels in time of war, but it is shown that only light rapid fire or machine guns could be carried on account of their light construction and limited deck space.

During last year 27,547 vessels entered and cleared at Canadian ports, as against 30,961 in 1892 and 31,321 in 1891. The total tonnage, however, last year was but little less than that of 1892, which was the highest in the history of the Dominion. It was 10,608,611 tons. A growing tendency is noted toward the construction of larger vessels every year. The number of vessels built in Canada in 1893 was 313, an increase of 35 over the previous year. As evidence of the decline in shipping values, however, it is noted that their average selling price has fallen from $37 per ton in 1868 to $11.50 per ton in 1893.

Utilization of Garbage.

The subject of the utilization of town refuse has been referred to from time to time in these columns, and it is one which is attracting an increased amount of attention in this country. In several cities of the United States there have been established various forms of crematories and destructors for garbage, but hitherto this material has not been turned to any very profitable account, as is the case in several European cities. The following details respecting the Livet process of utilizing city refuse will, therefore, be found interesting. This process is being favorably regarded in Europe, where it has been adopted in several quarters:

The Livet Process.

The Livet apparatus, as described by English journals, involves the rapid and economical generation of heat in furnaces and the utilization of dust and refuse for electric lighting. There is no novelty about the special objects of this process, which are: 1, The disposal of solid town refuse, whether wet or dry, by burning. 2, The utilization or the conversion of the products of the combustion of the said refuse into steam. 3, The employment of the steam so generated for electric lighting, for pumping sewage and for a variety of other purposes. 4, The manufacture of a kind of cement or mortar out of the residue or by-products of combustion, or the use of them, in combination with tar or bitumen, for footpaths and sidewalks, or the employment of the clinker for the foundation or bottoming of ordinary roads. The special feature of this furnace is that the form of the flues is such as will utilize the increasing weight of the products of combustion or gases as they travel toward the chimney, promote a high velocity of the air passing through the furnace bars, produce a rapid combustion with intense heat, and cause the gases themselves to pass sufficiently slowly through the flues to part with all their useful heat before they escape into the atmosphere.

English Methods.

The process is greatly facilitated by the fact that the solid refuse of English cities contains about 80 per cent. of mixed cinders and ashes, and thus provides in a great degree the materials for its own ignition and combustion. The method adopted in English cities is to deliver the refuse free of charge at the furnace mouth in a raw state, and shovel feed it into the fire without any preliminary drying, shifting or screening, an important point in the process. There is no unpleasant odor, as the high temperature and great force of draft secure complete combustion. The average quantity of rubbish burned per hour per square foot of grate surface of the Livet generator is 33 pounds, and 4 pounds of water is evaporated per pound of rubbish containing 20 per cent. of moisture. There is an excellent arrangement by which the flues are kept perfectly free and unclogged, even after months of use; the progression of the gases is partially arrested at the end of each flue, and the objectionable light dust is deposited in suitable expansion chambers or pits, which can be cleaned out as required.

Production of Electricity.

The value to a city of an effective apparatus for refuse utilization is shown in the recent installation at Halifax, England, which is equal to the production of current for the supply of 10,000 incandescent lamps of 10 candle-power for six hours a day, when 3000 tons or one-third of the rubbish of the city is burned. If the capacity of the plant were equal to burning all the rubbish produced, one lamp to each inhabitant could be supplied for three and a half hours daily.

While Coxey and others are marching on Washington with their hosts of "the unemployed," the farmers in the Eastern part of the country are crying out for more help, and the Free Immigrant Labor Bureau in New York announces that it is unable to meet the demands upon it for laborers. In the West, too, a similar condition of things prevails; prices for farm labor are higher than ever and the supply is inadequate.

The *Hungarian Metal Worker* says that an extraordinarily tough luting for pipes which have to stand pressure is made by mixing five parts of Paris white, five of ocher, ten of litharge, five of red lead and four of black oxide of manganese, very thoroughly together, and then adding a little asbestos and boiling oil.

The Canadian Minister of Public Works has entered into an agreement with the contractors by which they will complete the new Canadian Canal at Saulte Ste. Marie by July 1, 1894, for an additional grant of money.

Less cotton is being planted this year in the South, but more attention is being paid to cereals and other food products.

THE RETAIL STORE.

Stove Repair Orders.

Murphy, Maclay & Co., Great Falls, Mont., write as follows concerning the question of stove repair orders: "We have recently noticed letters from readers of the paper giving their systems of keeping account of stove repair orders. We have been using blanks similar to the inclosed, which have proven entirely satisfactory. We give the blank to the customer to fill out, requiring a partial payment in advance of ordering, so that the customer will be sure to call for the repairs when ready. The blank is self explanatory. We order from it and file it away until the repairs are received. On receipt of the castings we tag them, stating the name and number of the stove, the name of the person ordering and promptly notify the customer by mail that we have received his repairs. In this way we have done a large trade in stove repairs without loss of any kind."

The blank inclosed by our correspondent is given below:

MURPHY, MACLAY & CO.,
GREAT FALLS.

Order for Stove Repairs.

For Mr.....

We require a part payment in advance before ordering repairs. No exception to this rule.

READ OTHER SIDE BEFORE FILLING.

It will be noticed that in one place the suggestion is made "Read the other side before filling." The matter on the opposite side of the blank consists of directions to be followed in ordering stove repairs; also of a broken view of a cook stove with all the plates numbered and the correct name of the parts given in tabular form below the cut.

Nested Stove Pipe.

The accompanying cuts show a nested stove pipe which Ruth, Patterson & Ruth, Alliance, Ohio, are manufacturing and marketing. The object of the invention is to devise a construction of joint which will be simple and economical in cost, readily packed into a small compass for storing and especially shipping, and put together without riveting or beating the seams. The end of one joint forms a band and encompasses the end of the adjacent joint and prevents its spreading, while the seam is so formed that the joint will not give inward. The seam is formed by slipping the right edge into the groove on the left, and held in place by a rivet at the bottom. It will be seen that the lower end of each joint is the only part secured, and when put together, the upper end is slipped into the lower end of the joint above, thus forming a tight joint, as shown in Fig. 1, which can be easily taken apart and put together. Fig. 2 is an end view and shows construction of seam. Fig. 3 shows the upper end spread and nested for storing in shop or domestic use, the advantage of which is at once apparent when storing the pipe during the warm season, as a number of joints can be packed into a space not much larger than that usually occupied by one. Fig. 4 shows the pipe packed for shipment, and for this special advantages are claimed. It is pointed out that ordinary stove pipe is shipped as double first-class freight, while this is rolled and wrapped in paper and is shipped as fourth class and in car lots as fifth class. The pipe is made in the usual sizes.

Nested Stove Pipe.—Fig 1.—Finished Joint.

Fig. 2.—End View of Joint.

Fig. 3.—Pipe Spread and Nested.

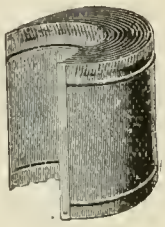

Fig. 4.—Pipe Packed for Shipment.

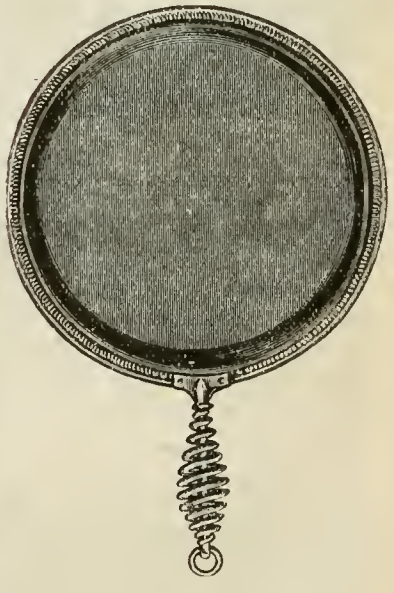
Crown Asbestos Griddle.

Hall & Carpenter, Philadelphia, Pa., are introducing the Crown asbestos griddle, as here shown. It consists of a sheet of asbestos covered with a circular sheet of steel, which has a single bead around the outer edge, the whole held together by a corrugated tin rim, crimped on so as to hold both firmly together. The handle is of wire, nickeled. The griddle is 9 inches in diameter, and is suitable for a number of purposes where the quantity required is not large, such as frying eggs, mush, hominy, cakes, &c. The placing of asbestos between the fire and metal prevents burning or scorching.



Crown Asbestos Griddle.

Relief Wringers.

The accompanying cuts represent two iron frame wringers offered by the American Wringer Company, 99 Chambers street, New York. The metal part of the wringer, Fig. 1, is all of wrought and malleable iron, galvanized, and the japanned springs are directly over the bearings. The upper arms are each provided with a pin which fits into an opening in the lower arm, with a heavy rubber gasket between the arms at the pin ends to relieve the strain. The clamps are of the swing pattern, allowing adjustment to round or straight surfaces. The wringer shown in Fig. 2 is of the same construction as the former, but in addition is provided with cog wheels. The manufacturers state that by the use of the thumb nuts and spiral springs the pressure can be adjusted quickly for either heavy or light work, preventing the rolls from being overstrained, and increasing the wear of the machine over that of the ordinary iron frame wringer.

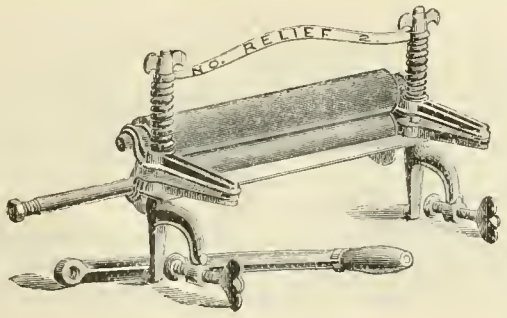


Fig. 1.—Relief Wringer.

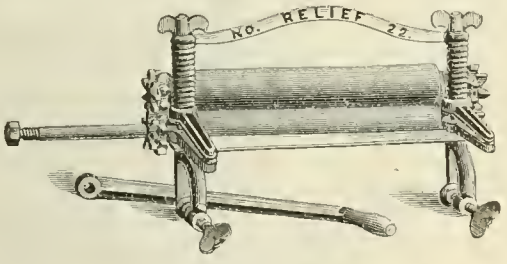

Fig. 2.—Relief Wringer with Cog Wheels.

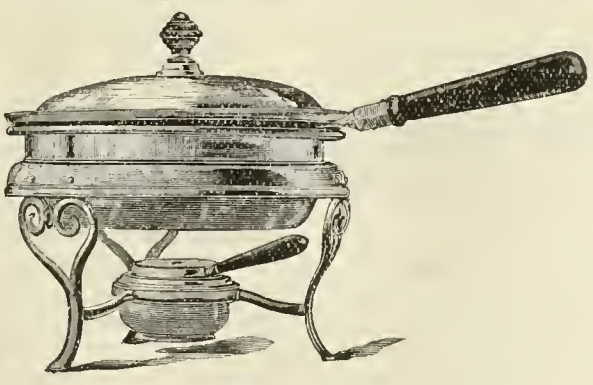
Aluminum Chafing Dish.

The Wohler Aluminum Company, 65 Jackson street, Chicago, have just placed on the market an aluminum chafing dish, herewith illustrated. There are a number of peculiar properties of aluminum which render the metal peculiarly well fitted for purposes of this character. The metal is not affected by either heat or acids and yet is an admirable conductor of heat. The heat conductivity of the metal used in making a chafing dish is an important consideration, as the fuel used is alcohol, and the claim is made that cooking can be done in an aluminum chafing dish with about two-thirds as much fuel as would be required for some of the heavy plated dishes. The purity of the metal is another important consideration, as any kind of food can be cooked in such a dish with no danger of contamination. The chafing dish is made wholly of aluminum except the handles, which are of wood, as usual. No solder is used, and the parts are therefore indestructible. The dish is made either highly polished or satin finished, closely resembling silver plate or solid silver, while it costs about the same as silver plate. The same company will soon place on the market a highly finished and elaborate tea pot, which they say will be the first to be made in aluminum in this country. It will be made with polished aluminum spout and handle. About the same time they will bring out an aluminum rice boiler, for which the patterns are already made.



Aluminum Chafing Dish.

The Philadelphia *Record* publishes a list of 25 "tramp" steamers which were obliged to leave that port in ballast during the first ten weeks of this year owing to inability to secure cargoes.

The Ellis Warming Box.

J. T. Ellis, manager, box 262, Newark, N. J., is offering a warming box as illustrated herewith. The box, as shown without the cover by a two-thirds sized cut in Fig. 1, is entirely of metal with an opening in the center 1⅝ inches in diameter. The bottom of the box is solid and the air space between the inside and outside walls is covered by a brass rim. The inside wall is of fine brass wire cloth, and the outside wall of perforated metal. The heat is supplied by checker shaped carbon with a hole in the center, which is placed on a pin in the center of the opening. This is lighted with a match, after which the cover is put on the box, having lugs for holding it securely in place. Air is provided through the openings in the walls or sides of the box to allow of slow combustion; one carbon, it is stated, giving heat for about two hours. Fig. 2 represents the box in a ring or handle, which allows of handling the box when heated. The box is designed for relieving pain by the application of heat in a more convenient form than hot water bags, bricks, &c.; to be used in case of earache, neuralgia, toothache, lumbago, rheumatism, colic, &c. The point is made that the box may also be used to advantage for keeping warm the hands of street car drivers, conductors, policemen, coachmen, teamsters, postmen, mechanics, farmers, school children, also ladies when shopping, calling, walking or driving. The box with rim measures 3½ inches in diameter, weighs 5½ ounces and is finished in nickel plate. The manufacturer claims that the heater burns freely in the pocket or other receptacle without flame, smoke or unpleasant odor when closed. Twelve carbons accompany each heater and additional carbons are packed 100 in a box.

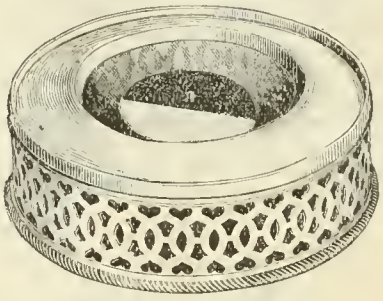


Fig. 1.—The Ellis Warming Box.

Fig. 2.—Warming Box in Ring.

Thomas A. Edison and Col. E. Gouraud have applied to the Court of Chancery, Newark, N. J., for the appointment of a receiver for the Edison United Phonograph Company. The bill claims that the directors of the corporation have pursued a policy contrary to the views of the holders of one-half of the company's stock, which has resulted in the wasteful and injurious operation of the concern and caused its insolvency.

STEAM AND HOT WATER.

The Ideal Water Heater.

We show in the accompanying illustrations a general and a sectional view of the Ideal water heater manufactured by the Ideal Boiler Company, Chicago, Ill., with temporary office at 88 Lake street, from where they will remove to 36 Dearborn street on May 1. The sectional view, Fig. 2, shows the interior water sections and the course of the circulation, while Fig. 1 shows the exterior form of the boiler, the method of connecting the sections, the position of the clean out doors, &c. Particular emphasis is laid upon the circulation of this heater. The water, it will be observed, enters on a level with the grate in the bottom section, flows around the fire pot and then enters a water column which communicates with the horizontal sections. These sections have the smoke holes staggered, so as to bring the products of combustion in more efficient contact with the surfaces. Each section is independent of the others and the manufacturers say is practically a separate boiler, so that when only a light fire is maintained the heated water rises directly to the flow pipe. The smoke flues in each section equal in area the opening for the smoke pipe. The hollow fire pot as shown in Fig. 2 is corrugated on its inner surface, and is furthermore slightly tapering in form, the grate diameter being larger than it is above, this shape, it is claimed, giving the most perfect combustion. The sections are fastened together by short bolts on the outside and the meeting surfaces are machine milled and made perfectly true. The only water joints are those which connect the sections together at opposite sides. It is pointed out that, if it is desired to increase the capacity of the boiler, other sections can be added. Furthermore, in case of accident, any section can be removed without difficulty.

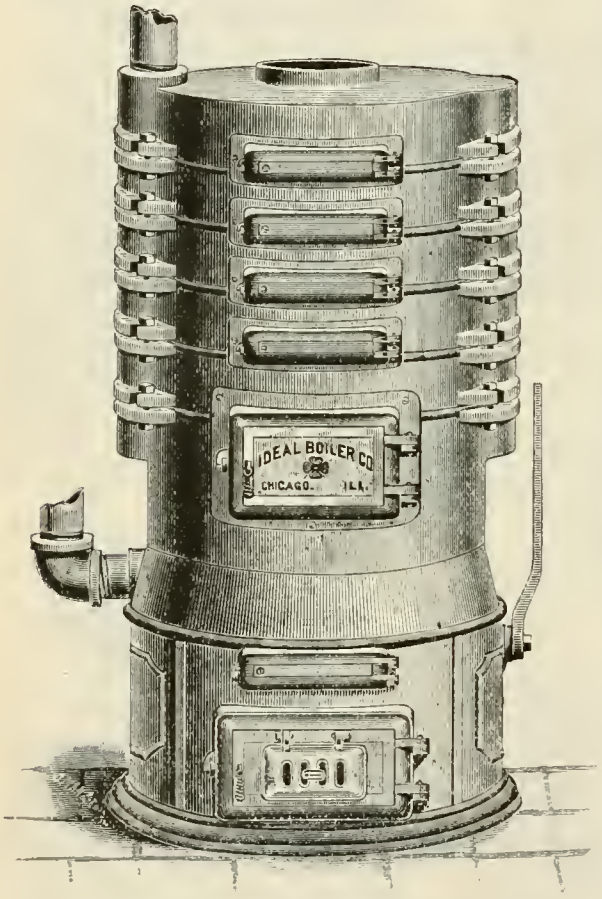

Fig. 1.—General View of Boiler.

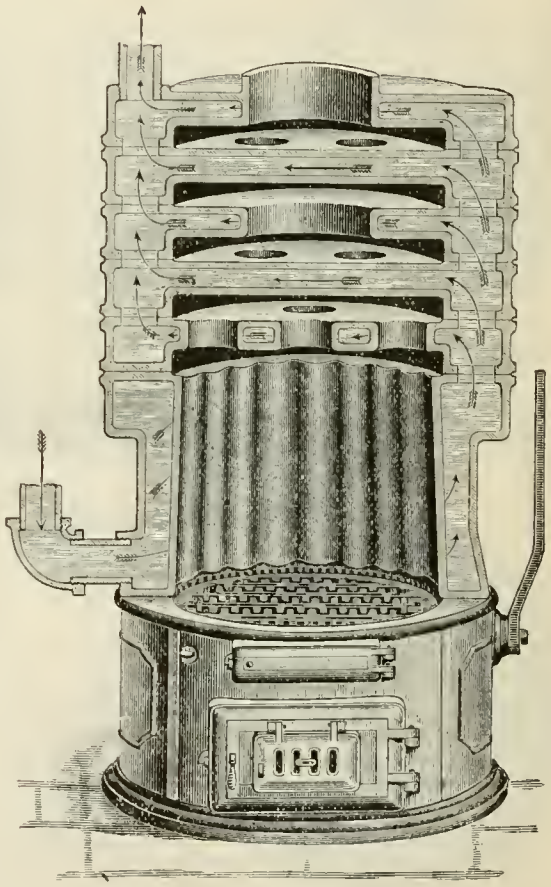

Fig. 2.—Sectional View.

THE IDEAL WATER HEATER.

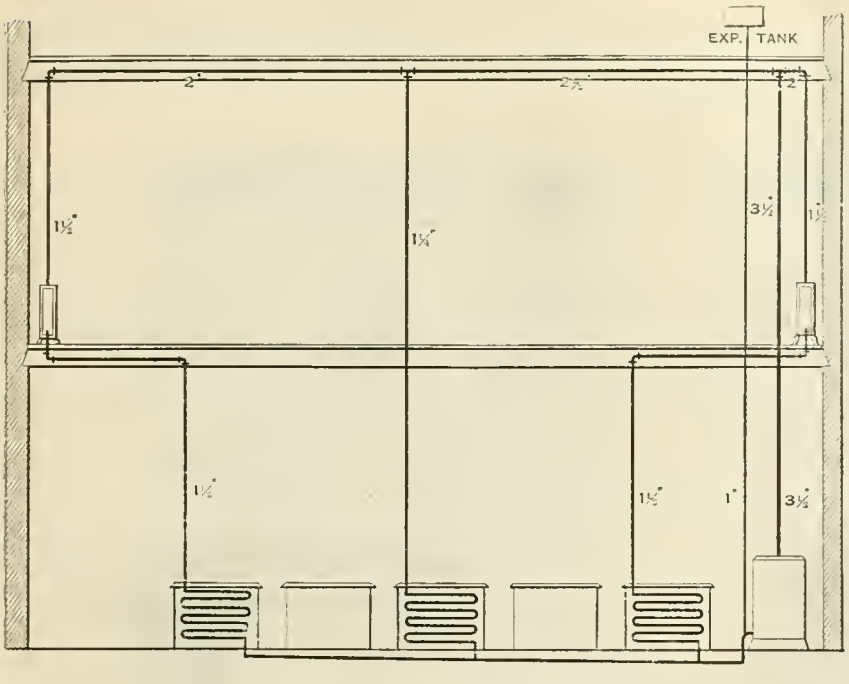
Radiation for Theater.

From MANAGER, *Nashville, Tenn.*—I have a theater to heat that seats on first floor 376 people, second floor 324 people and gallery 340 people. The stage has a very high ceiling and will be very hard to heat, and if it should be lacking in radiation when the curtain is raised a draft of cold air is thrown into the auditorium, making it very uncomfortable for the audience. We should allow something for animal heat in auditorium, taking an average house as a basis to figure from. I have had a great deal of trouble in getting the right amount of radiation in stage and auditorium, and would be glad for you to tell me through the columns of your excellent paper how strong to figure it. The building is to be heated with hot water.

Note.—Some of our readers have had experience in this line of work and we hope they will give the rules they have used. On consulting a number of engineers there is a similarity of opinion that each case requires different handling, and with direct radiation there is more difficulty in avoiding air currents than with an indirect system. There is less probability of air currents if the same radiation is used, in proportion to the space, back of the curtain as in front of it. In the locality from which the inquiry comes it is probable that with hot water 1 square foot of surface would be sufficient for 200 cubic feet of space. The radiation used back of the curtain is preferably arranged along the outer walls.

Wants a Heating System.

From W. A. T., *Buffalo, N. Y.*—If our Tennessee friend who asks for a heating system in *The Metal Worker*, March 10, had given a plan of his 22 x 125 feet dry goods store, less difficulty would be encountered in assisting him. I give a plan of a supposed store and a method of installing a hot water plant for heating it. As the expense of a basement is to be avoided, the boiler must set on the first floor unless there is space behind the store to erect a building to set it in, which would but slightly change the general arrangement shown in Fig. 1, and would not interfere with the operation. As the upper floor will be more easily heated, 1 square foot of heating surface will be sufficient for 70 cubic feet of space, as the piping aids in heating. On the first floor 1 square foot of surface is used to 50 cubic feet of space, as the water in four of the radiators will pass through the upper radiators before reaching them. On the upper floor the surface has been placed in four radiators of 100 feet each, two at the front and two at the back of the building, as shown in Fig. 2. On the lower floor six coils of 100 feet each are placed in front of the counters, one on each side of the store, at the front, middle and back, as shown in Fig. 3. The radiators in the middle of the store are fed with a pipe direct from the main, but the front and back radiators are fed by the return from the upper radiators. The floor of the store will have to be taken up to run the return, and all of the branches should be connected to it with Y fittings. The return should have a fall all the way to the boiler, then rise and connect with it. The highest point in the system should be where the rising flow main branches, and an air valve should be placed there, and from this point there should be a slight fall in all the pipes to let the water as it cools fall back to the boiler. A pipe should be connected with the return at the boiler and run up to the expansion tank located above the top of the flow main, and in the space above the second-story ceiling if there is room. Another method of heating the lower floor would be to arrange the coils on the ceiling, which would avoid running the return under the floor, but as the greatest heat would be on the heads of the clerks and customers it is doubtful if such a labor saving plan would be advisable.



Wants Suggestions on Heating.—Fig. 1.—Showing General Arrangement.

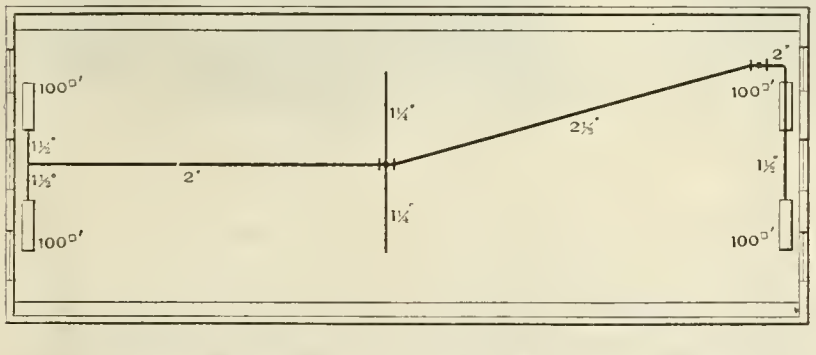


Fig. 2.—Plan of Second Floor, with Flow Main and Radiators.

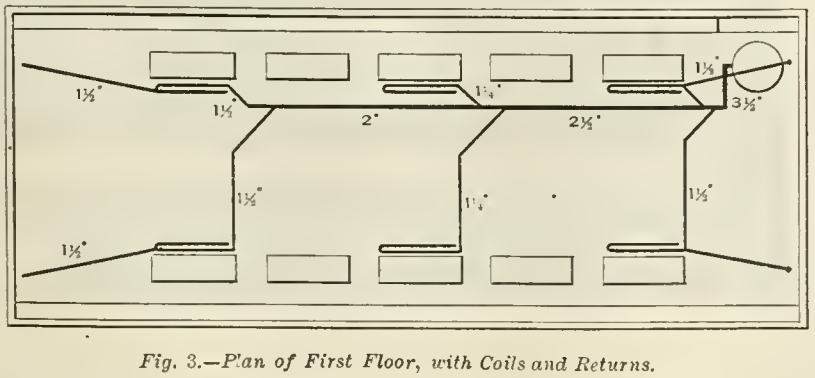

Fig. 3.—Plan of First Floor, with Coils and Returns.

Automatic Pump Governors.

In *The Metal Worker*, March 24, was an article entitled "The Value of Exhaust Steam for Heating," which described a system of returning the water of condensation to the boiler by means of a steam pump and an automatic pump governor. After the publication of the article we were informed that the essential feature of the system, which was the automatic pump governor, was controlled by patents owned by the Albany Steam Trap Company, Albany, N. Y., who had licensed Timothy Kieley, 7 to 11 West Thirteenth street, New York, to manufacture the governors, and that litigation was now in progress with other manufacturers. We quote as follows from a letter received from the Albany Steam Trap Company in reply to our inquiry respecting their interest in the patents and system:

The pump governor or regulator is the main feature of the system you described in the article in *The Metal Worker*, March 24. There are several parties making these devices, and as we believe in violation of our patented rights, as we are the owners of the patents numbered 207,483 and 207,485 fully covering the automatic regulation of steam pumps for returning the water of condensation from steam heating systems under pressure. We have a suit against the Worthington Pump Company, claiming that they infringe the claims in the patents above named. We have licensed Timothy Kieley of your city to manufacture pump governors under our patents. All other manufacturers of pump governors controlled and operated by the condensed water of the heating systems we claim are infringing our patents.

T. C. Joy & Co., Titusville, Pa., manufacturers of the Joy flue radiators, with offices at 48 Centre street, New York, and 96 Lake street, Chicago, are sending out a circular with a list of the large buildings, with the names of the architects and heating engineers, where their radiators are used. Two carloads of radiators were recently received for the Manhattan Life Insurance Company building, in which Gillis & Geoghan are installing the heating plant.

R. T. Crane of the Crane Company, Chicago, has been superintending some of the transfers connected with the purchase of Huntington-Hopkins Company stock of pipe and fittings at San Francisco, Cal.

Scollay's Improved Boiler.

The accompanying illustrations show the improved hot water boiler being placed on the market by John A. Scollay, 74 and 76 Myrtle avenue, Brooklyn, N. Y. Fig. 1 shows the complete boiler, and Fig. 2 is a sectional view showing the internal arrangement. It has a labor saving grate and the lower fire pot is lined with fire brick. Above these is the water chamber, or dome, with an inner chamber directly over the fire which has both corrugated surface and projecting tapering studs to increase its efficiency as a heat absorbent. The inner chamber connects with the outer chamber both at the sides and at the top. The flow and return main connections are at the top and bottom of the boiler. A draw off cock is placed at the bottom to empty the boiler. The boiler proper has an outer non-conducting casing with a casing ring so made and placed as to form a baffle plate to cause an indirect draft. There is a smoke outlet at the back connecting with the boiler both at the top and at the bottom, and when the damper at the top is open there is a direct draft, but when it is closed there is a full reversed indirect draft. The boiler is known as the C series and is made in four sizes rated to carry from 250 to 1000 feet of radiation. Some of these boilers have been used for both residence and greenhouse heating during the winter with satisfactory results.

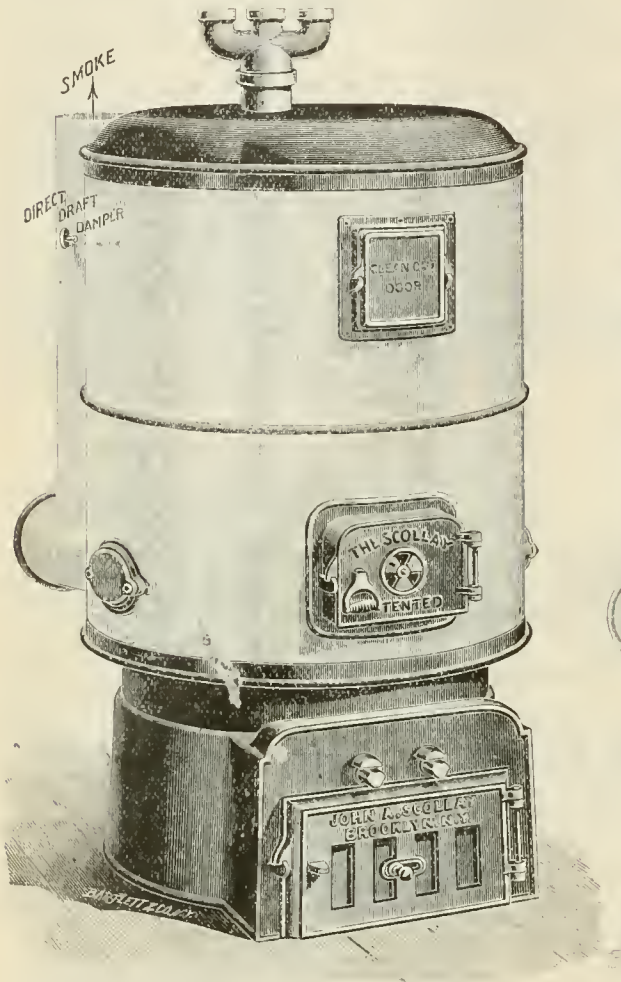

Fig. 1.—Showing Boiler Complete.

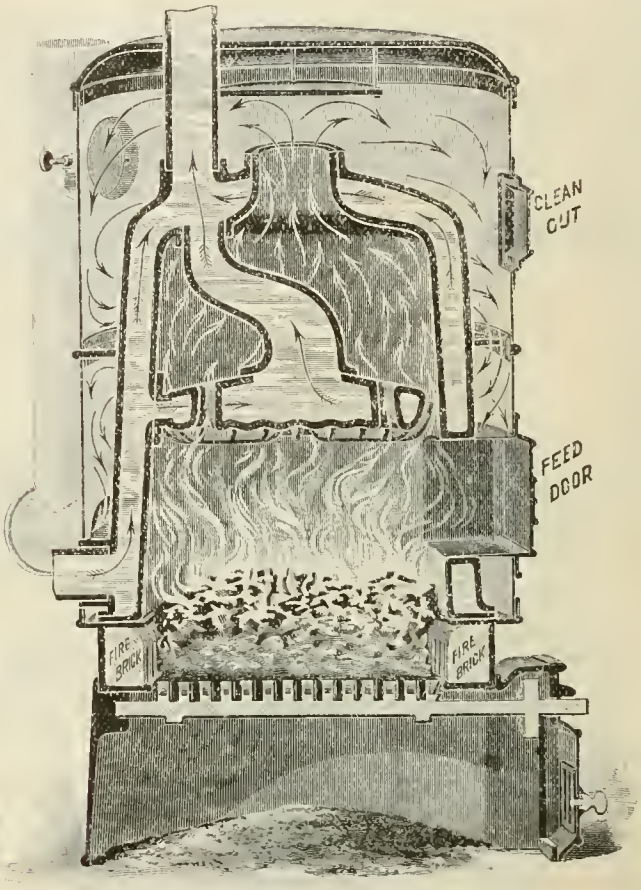

Fig. 2.—Sectional View.

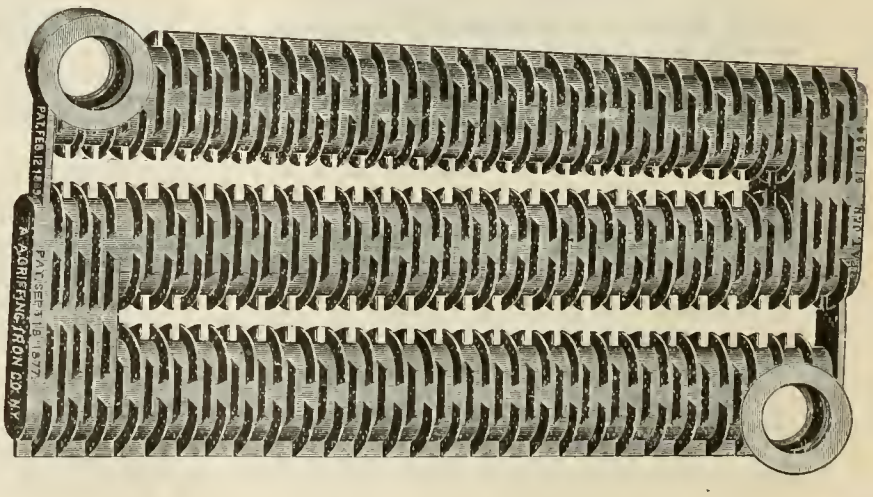
SCOLLAY'S IMPROVED BOILER.

The Bundy Newport Radiator.

The illustration herewith shows a section of a new indirect radiator made by the A. A. Griffing Iron Company, Jersey City, N. J. It is of the extended surface character and each section has three arms. The sections are 37 inches long, 3½ inches wide and 15 inches deep, and are made up into stacks, with heavy 2-inch right and left hand hexagon nipples. They are equally adapted for use with steam or hot water, the openings being at the extremities and the return opening below the water way of the radiator to aid a gravity return. The construction, it is said, insures a positive circulation of either water or steam.



The Bundy Newport Radiator.

The Ideal Boiler Company have recently been incorporated in Chicago, with a capital stock of $100,000, and will manufacture and put upon the market a complete line of steam and hot water boilers. It is the purpose of the company to manufacture boilers with circular fire pot and horizontal sections, and also boilers with square fire pot and vertical sections, with a

view of carrying a line of house heating boilers which shall be surpassed by none in the trade. The president of the company is Geo. E. Downe, late president of the National Hot Water Heater Company, who is well known to the trade in all sections of the country. The new company have leased for their Chicago headquarters the store at 36 Dearborn street, recently vacated by the American Boiler Company.

HEATING NOTES.

THE UNITED STATES HEATER COMPANY, Detroit, Mich., send out a card illustrating their line of heaters, which includes the Capitol, Mascot and Hecla.

H. GILBERT HART, of Hart & Crouse, Utica, N. Y., manufacturers of the Royal line of heating apparatus, will sail for Europe next Tuesday.

THE EXETER MACHINE WORKS of Boston, Mass., manufacturers of the Exeter steam and hot water radiators, have made arrangements with the John Simmons Company, 106–110 Centre street, New York, to handle their goods exclusively in New York State. They are prepared to fill all orders promptly.

THE MODEL HEATING COMPANY, Philadelphia, are sending out a handsome piece of printing in the interest of the Novelty Circulator. It is a four-page card, with a half-tone engraving on the first page of the Novelty Circulator in the latest form, with the text in red and dark green, while the last page is devoted to dimensions, ratings and prices.

GEO. B. CODE & CO., 96 Centre street, New York, have bought out the Welsbach Light Company's Harlem branch store, at 155 West 125th street, where they purpose establishing an uptown branch of their steam and hot water heating business. Their fine display of gas stoves, ranges and Welsbach lights indicates that their gas appliance department, under the superintendence of A. J. Doty, is in very capable hands.

HART & CROUSE, Utica, N. Y., had as a visitor this week Manager W. M. Mackay of their steam and hot water department, at 211 Water street, New York. Mr. Mackay states that the New York Central road is preparing to lay a branch into their new works, which will soon be in course of construction.

THE D. S. MORGAN BOILER COMPANY, 23 West Lake street, Chicago, have released their present location for a term of years.

THE SMITH & ANTHONY STOVE COMPANY, 217 Lake street, Chicago, have secured the agency of the United States Radiator Company, and will carry a full line of their Splendid radiators.

WE ARE INDEBTED to the Richmond Stove Company, Norwich, Conn., for a batch of the pretty catalogues that they are issuing in the interests of their agents. They are small, neatly published and printed pamphlets, containing descriptions and illustrations of their steam and hot water heaters, and each one is issued in the name of some special firm, and at the back of the different pamphlets are testimonial letters from persons who have used the Richmond goods in the neighborhood of the agent. One of these pamphlets carries the name of the Fall River Steam & Gas Pipe Corporation, 93 Pleasant street, Fall River, Mass.; another is issued in the interest of Abram Knowles, New Bedford, Mass.; a third is issued for Paul B Patten, 16 Lafayette street, Salem, Mass.; a fourth for J. H. Alvord, Winsted, Conn. A fifth pamphlet, of larger edition, carries on the front cover and title page the firm name of Isaac Coffin & Co., 52 Sudbury street, Boston, Mass.

W. B. WILKINSON, at 210 Water street, manager of the New York branch of the Howard Furnace Company of Syracuse, N. Y., is showing a method of connecting a combination hot water and hot air furnace with a radiator. The furnace is near a column which supports an expansion tank near the ceiling and a radiator beneath, with all the piping, angle valves and air valves, just as required in practice.

"ROYAL HEATERS: Hart & Crouse, Utica, N. Y.; 211 Water street, New York. Steam boiler catalogue, 1894," is on the cover of a 24-page catalogue which has just reached us. In it are several desk blotters printed in two colors, proclaiming the features and attractions of the Royal line of heating apparatus. The catalogue is devoted to describing the Royal steam heater, with cuts showing construction and operation. Two pages are devoted to ratings for both residences and greenhouses. A full list of the trimmings of the heater is given, with instructions for setting it up and directions for using it.

THE HARELL STEAM HEATING COMPANY, Dunkirk, N. Y., have by special act of the Legislature assumed the name United States Radiatior Company. They manufacture cast iron radiators exclusively and the name Harell Steam Heating Company was misleading, inasmuch as many of the trade assumed that they were engaged in the steam heating business. The new name is comprehensive and appropriate and the management have shown excellent judgment in its selection. We understand that they are erecting new buildings and increasing their output in order to meet the demand for their Splendid radiators. The firm expect to issue a catalogue illustrating and describing their different specialties and which they will distribute to the trade.

ALFRED EMLEY of Emley & Sons, Limited, dealers in marble and plumbers and heating engineers, of Newcastle-on-Tyne, England, was a guest of J. A. Goodrich of the American Radiator Company at 92 Centre street, New York, this week. He visited a number of houses in the heating goods and fitting and supply trade, and expressed surprise at the conveniences of the goods used here. He is now making a more extended tour through the United States, and it is probable it will result in some trade in goods manufactured in this country.

W. M. MACKAY, manager of the steam and hot water department, at 210 Water street, New York, of Hart & Crouse of Utica, is displaying a Royal hot water heater, set up ready for use, in front of the store. It is attractively painted and decorated.

VISITORS to the American Radiator Company, 92 Centre street, New York, will notice that their showroom has been pleasingly rearranged. The back portion of their building is now divided from the showroom by hardwood and glass partition, which includes a private office for J. A. Goodrich and coat and toilet rooms. Back of these are arranged storage closets and shelves for stationery and filing correspondence. Immediately in the rear are the warerooms, the basement floor being used for both the storing and construction of radiators. The ground floor is used for preparing radiators for shipment. Iron strapped wooden cases are more frequently seen as the foreign shipments are on the increase. The beauty of the radiators made in the United States finds a market for them in Europe, South America and Japan. At the front of their showroom radiators of artistic decoration are shown. Radiators in imitation of porcelain are exhibited and decorated in a harmonious combination of coloring and enlivened with gold. In contrast radiators are shown in various electro-bronzes from deep copper to bright brass, and the new aluminum bronze for radiators is a novelty in ornamentation.

The Kewanee Boiler Company

of Kewanee, Ill., and Dearborn and Lake streets, Chicago, have brought out a new and very comprehensive catalogue, No. 3, covering boilers of all kinds for power and heating. This catalogue is of pocket size and contains 128 pages. An introductory chapter gives some particulars about the company's new factory, which is equipped with the most modern boiler making machinery, including hydraulic riveters, hydraulic cranes up to 20 tons capacity, pneumatic lifts, machines for flanging heads and fire boxes, large bending rolls, plate planers, punches, &c. Attention is next called to the high quality of materials used in making the various products turned out by this company and the very thorough tests given all boilers before leaving the works. The catalogue proper begins with illustrations of power tubular boilers, which are shown in different settings and in a variety of styles. These are fitted with the Ætna shaking grate, the Kelly rocking and dumping grate, the Haxtun rocking and dumping grate, Burnham's patent rocking and dumping grate, or common grates. Next come fire box flue boilers for steam heating, vertical tubular boilers, vertical flue boilers, feed water heaters, &c. The Anderson steamer is an apparatus for cooking food for stock or for use in slaughter houses. A line of water heaters is made for laundry and bath purposes. Receiving tanks for steam heating apparatus are shown. The company manufacture all kinds of tanks.

Special attention is called to the Haxtun boiler for steam and water heating. It can be used for hard or soft coal, and is a base burner with either fuel. Illustrations of this boiler are given in brick setting, with part of the brick work removed, in cross section, showing the distribution of water, &c. Several patterns of grates are made for this boiler, illustrations and descriptions being given of each style. The company are jobbers of steam and water supplies, furnishing complete outfits of pipe, fittings, radiators, valves, gauges, &c., for steam and water heating systems. The catalogue contains very full price-lists of these supplies, as well as of the company's own products.

A new material for paving is being introduced into London. It is composed of granulated cork and bitumen pressed into blocks, which are laid like bricks or wood paving. The special advantage of the material lies in its elasticity. In roadways it furnishes a splendid foothold for horses, and at the same time almost abolishes the noise which is such an unpleasant feature of city traffic. It is used in Australia with good results.

ROOFING AND CORNICE.

Roof Flashings.

From B. W., *Milwaukee.*—One of the important parts of a roof is the flashing, or connection between the roof and wall. One of the first methods I used for the purpose is shown in Fig. 1. The tin was laid in the wall by the mason, thus securing a tight joint. After the roof was laid the flashing was bent down and out so it could be nailed to the roof. In this instance tinned nails were used, so they could be easily soldered. In time the nails worked through the solder and caused leaks. When nails are to be used as shown in Fig. 1, it is best to drive them through this joint should break, it is supposed the bent tin behind the flashing would prevent water from entering the building. Some tinners prefer to have a 2 x 4 strip laid in the wall, as shown in Fig. 5. After the brick work is finished, the joint above wood can be cut out by means of a coarse saw, then after sweeping the roof boards the flashing can be placed in position and secured by nailing into the wood. The joint is to be cemented in the usual manner. A strip of tin can be laid in the wall and then bent over the roof tin, as shown in Fig. 6, or a lock joint can be made between the two, as shown in Fig. 7. By the methods thus far presented the flashings have been placed against the wall, thus producing a right angle. Some tinners prefer to have the flashing placed at an angle, as shown in Fig. 8. A strip of wood is secured to the roof boards, and against this strip the flashing is laid; thus abrupt bends are avoided.

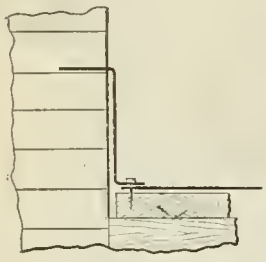


Fig. 1.—*Head of Roof Nail Exposed.*

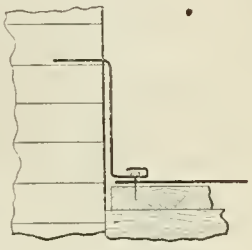

Fig. 2.—*Head of Roof Nail Covered.*

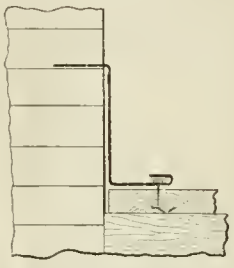

Fig. 3.—*Lock Turned on Flashing.*

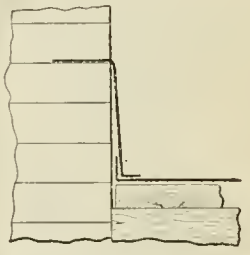

Fig. 4.—*Flashing Bent Over Roof Tin.*

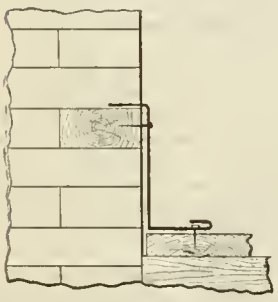

Fig. 5.—*Flashing Nailed to Wood in the Wall.*

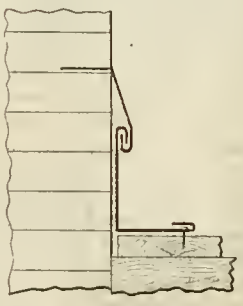

Fig. 7.—*Strips Joined by Means of Lock Joint.*

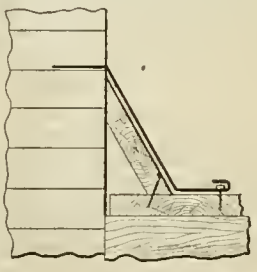

Fig. 8.—*Strip of Wood Placed Behind Flashing.*

ROOF FLASHINGS.

strips of tin cut about ½ x 1 inch, thus allowing the ends of the strips to be bent over the nail heads and soldered. Another method of securing the flashing to the roof is shown in Fig. 2. After the roof is laid the flashing is bent down and out, then an edge is turned up so the flashing can be nailed, when the edge is turned over and soldered. While this method allows the nail heads to be covered, two edges are to be soldered in the place of one, as in the previous instance. By laying the flashing in the wall, then bending down and out, as shown in Fig. 3, a lock can be turned over and secured to the roof boards by nails or cleats, when the roof tin can be joined in the usual manner. In Fig. 4 the roof tin is shown bent up against the wall. After the roof has been soldered the flashing is bent down and soldered to the roof, and if

FLASHINGS.

We are indebted to J. H. Eller & Co., Canton, Ohio, for a copy of their handsome illustrated catalogue for the current year. It is a volume of nearly 100 pages, bound in colored paper with raised design on the front cover printed in bronze. It is the eighth edition of the catalogue, and in it the manufacturers call attention to several new features, especially their improved lock seam steel roofing, plain, round and octagon expansion conductor and a full line of cornices, cresting, finials, vanes, &c The volume begins with general remarks on the construction of steel roofs and rules of measurement and other matters of interest to the trade. This is followed by sectional and other illustrations of roof seams and methods of laying roofs. The next division is given up to corrugated iron of different sizes of corrugations, weather boarding, crimped iron, beaded iron, hip coverings, pressed steel brick, rock faced brick, siding, &c. Then comes the division of the catalogue relating to galvanized iron and tin eave troughs, corrugated and plain round conductor pipe, elbows, shoes, cut offs, strainers, &c. Round and octagon expanding conductor, galvanized iron cornice, crestings, finials, ornamental hip caps, weather vanes, &c. The book is profusely illustrated, and in addition to the prices full information is given of the articles referred to.

The East Birmingham Iron Roofing & Corrugating Company, Birmingham, Ala., distribute a highly ornamented postal card, which calls attention typographically and pictorially to their pressed standing seam roofing.

Charles Schaeffer, one of the best known sheet metal workers of Chicago and for years a writer on practical subjects for the trade press, has engaged in the cornice business with his brother. Their establishment, which is styled Schaeffer's Cornice Works, is located at 1014 to 1022 Central Park avenue, cor-

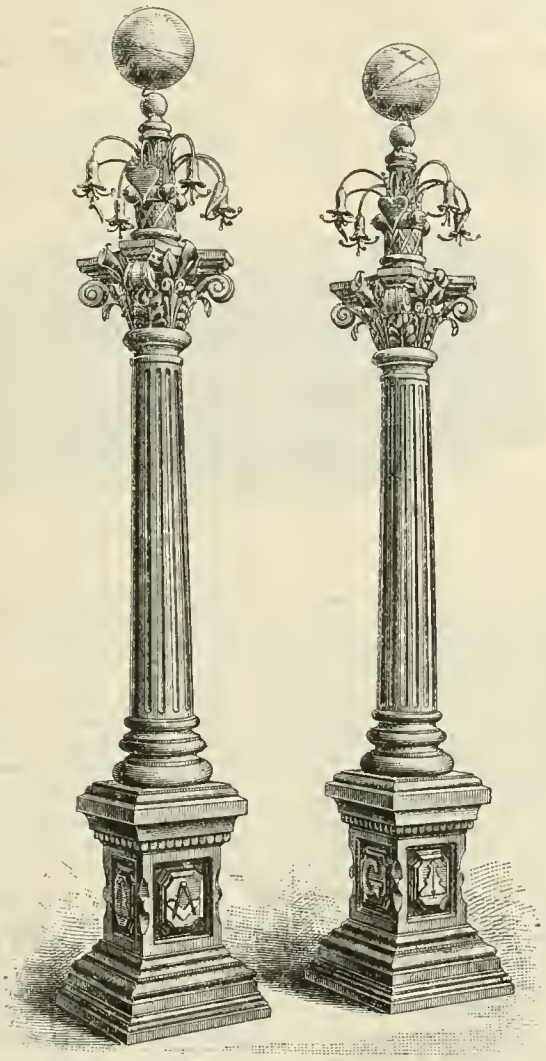
ner of Twenty-second street, Chicago. They make a specialty of artistic and round work.

The Acme Roofing Company, Canton, Ohio, issue a handsomely published illustrated catalogue and price-list of their manufactures, which include a full selection of sheet metal goods in the roofing and kindred lines. The first articles noted are eave troughs and gutters with gutter hangers. Then come conductor pipe and conductor heads, followed by elbows, rain water cut offs, ventilators and ridging. Cresting blocks and finials are illustrated in many styles. A number of pages are given to cornices, showing a number of different architectural designs. Finials are likewise illustrated and then attention is given to skylights. The second section of the catalogue is devoted to roofing, and the goods noticed are the Acme standing seam steel, roll cap, double seam, folding seam, pressed standing seam, corrugated pressed standing seam, corrugated iron siding, steel pressed brick, weather board siding, ceilings, &c. The volume is profusely illustrated and is indexed at the back. The cover is of heavy colored paper with the name and address stamped on the front and printed in gilt.

Messrs. Hill & McGinty, who have wbeen for many years ith E. B. Badger & Son, Boston, Mass., have started in business for themselves at 20 and 22 Pitta street as sheet metal workers, coppersmiths and roofers. Mr. Hill was confidential clerk and bookkeeper for Messrs. Badger & Son for 25 years and Mr. McGinty has been with them as foreman for the past 15 years. Their former associates gave Messrs. Hill & McGinty a handsome oak roll top desk last Saturday, the presentation speech being made by Thaddeus Flynn.

Sheet Metal Columns.

We present in the accompanying engraving an illustration of a pair of sheet metal columns that will be of interest to many of our readers. The following letter, which was received with the photograph of the work from Barrett, Hicks & Co., Fresno, Cal., contains a brief description of it:

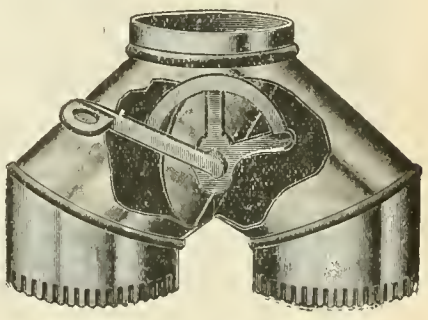


Sheet Metal Columns.

We inclose you photograph of a piece of work just completed by our cornice maker, Jack Dressel. It is a little out of the ordinary line and our Masonic friends will immediately recognize what the columns are intended for. The columns are made of galvanized iron, except the leaves, flowers and work around the capitals, which is hammered copper work done by hand. All columns of this kind which we have ever seen have been made of wood, and as our weather is so hot in summer it occurred to us that these could be gotten up of galvanized iron to stand any weather and any climate. So we undertook the job, and think we have made satisfactory work of it. The columns are 22 inches square at the base and 12 feet high. The globes on top are 12 inches in diameter. The shaft can be removed from the base, which is intended to be filled with sand.

The Acme Rain Water Cut Off.

We show in the accompanying illustration a broken view of the Acme rain water cut off, manufactured by the Acme Roofing Company, Canton, Ohio, and on which a patent is pending. Special attention is directed to the simplicity of its construction and to the fact that it cannot be turned by the water. It is pointed out that there are no springs to get out of order, break or become loose. The Acme cut offs have been manufactured and sold for a year, and wherever used have, we understand, given excellent satisfaction. The cut offs are made of the best grade IX bright plate, japanned, and also of galvanized iron, in all sizes.



The Acme Rain Water Cut Off.

Net Price of Galvanized Sheet Iron.

We have had a number of inquiries for copies of the table giving the net price of galvanized sheet iron which was printed in *The Metal Worker*, April 7. We have, therefore, issued the table in more permanent form, published on manilla card suitable for shop and office use. The card will be sent on receipt of 10 cents by David Williams, 96-102 Reade street, New York.

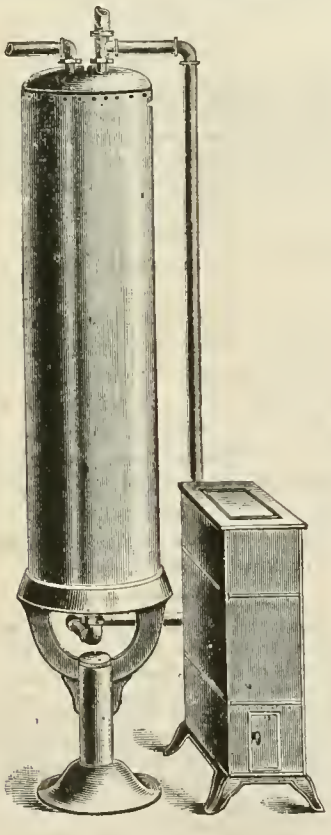
Senatorial obstructionists at Washington would do well to ponder the methods of the Canadian Parliament in the dispatch of financial business. Canada's new tariff went into effect on March 27, a few hours after it had been brought down to the Assembly by the Minister of Finance. At 3 o'clock that afternoon all the telegraph lines were monopolized by the government, and by 8 a.m. the next day every custom house in the Dominion—some 800 in number—was in possession of the new tariff in full.

According to the *Puget Sound Lumberman*, the output of lumber in the State of Washington for 1893 was of the value of $10,700,000, in addition to $2,636,000 of shingles. The figures in feet were: Lumber, 764,234,912; shingles, 1,829,528,500. This was greater than the output of Oregon, British Columbia, Montana and Northern Idaho combined.

PLUMBING and GAS FITTING.

Vulcan Water Back.

W. M. Crane & Co., 838 Broadway, New York, are introducing the Vulcan water back, as here shown, to be used in connection with gas. It is made of cold rolled steel and angle iron in two sizes. No. 1 is 27 inches high, 16 inches deep and 8 inches wide. No. 2 is twice the width of No. 1, the other dimensions being the same. Between the outer steel casing and the water back within is a lining of either soapstone or fire brick, which has a covering also of mineral wool as an economizer of heat. It is fitted with their patent socket burner, which can be instantly removed for cleaning, and has an adjustable air mixer which they refer to as suitable for any gas. The heated water passes in at the top of the boiler, gradually forcing its way down. An advantage is claimed that in drawing water at the faucet it is not necessary to wait until the entire mass has been heated, it being possible to draw directly from the water back or that portion in the top of the boiler. The No. 1 is for 30 to 60 gallon boilers,



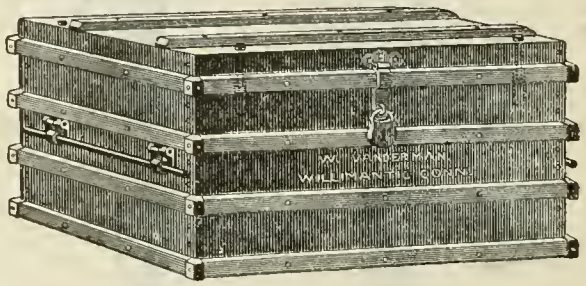
Water Back for Gas.

and consumes, they state, 30 cubic feet of gas per hour. No. 2 has just twice the capacity, and consumes double the quantity of gas. When the water is once heated the supply of gas can be reduced to 20 feet an hour.

In response to the call of President Daniel G. Finnerty of the National Association of Master Plumbers, the plumbers of Vermont met April 11, at Rutland, and organized a State association, which has affiliated with the Nation Association and will be represented in the convention at Detroit. The officers are: President, W. P. Jones, Rutland; treasurer, E. A. Valiquette, Rutland; secretary, E. H. Bagley, White River Junction.

Vanderman's Steel Tool Chest.

The Vanderman Plumbing & Heating Company, Willimantic, Conn., are putting on the market a tool chest made of steel which is intended to take the place of the ordinary tool chest used by plumbers, steam fitters and others. A general view of the chest is shown in the accompanying illustration. The material of the chest is $\frac{1}{16}$ inch sheet steel, with malleable iron corner pieces and hardwood braces, as shown, and is fitted with bolts to secure the cover, and furnished complete with hangers, lock, key and wood drawer. The manufacturers say that it cannot be broken or bent out of shape by any use to which a tool chest is put. The chests, which are finished with paint, are made in three sizes—11 x 12 x 24 inches, 14 x 15 x 30 inches and 16 x 17 x 36 inches, the weights being, respectively, 40, 60 and 75 pounds.



Vanderman's Steel Tool Chest.

TRAPS AND VENTS.

The Mechanics' Supply Company, 96 St. Peter street, Quebec, Canada, issue what they term "A Gentle Reminder." It is a folded card directing attention to their business and the goods they handle, which comprise gas, water, steam and plumbing supplies.

Barrett & Wallace are a new firm at Cohoes, N. Y., who will do tinning, plumbing, gas fitting and steam and hot water heating.

The uptown store of the J. L. Mott Iron Works, at 147 West Thirty-fifth street, New York, is largely used by plumbers to show the different styles of baths, closets and fixtures to their customers, owing to the fine display there made.

The Stewart Ceramic Company, 312 Pearl street, New York, are making some substantial improvements to their premises. Their office is now located on the first floor and their sample room has been enlarged to double its former size. This enables them to make a fine display of their solid white crockery washtubs and butler's pantry, corner, slop and kitchen sinks. They are also showing a bathtub of their manufacture which is one of their newest productions.

John Tucker of New York has opened a first-class plumbing establishment at 32 Bellevue avenue, Newport, R. I.

Disley & Weyland have purchased the large vacant lot on the south side of Jefferson street, Waterbury, Conn. The property has a frontage of 60 feet on Jefferson street, with a 10-foot driveway. They expect to build a three-story block for their plumbing and cornice business.

Hayward & Reynolds are a new plumbing firm at 335 Columbus avenue, New York. They were formerly with the Durham House Drainage Company.

Supplies for the steam fitter, gas fitter and plumber are the specialties of W. H. Hussey & Son, 150 West Thirty-fifth street, New York.

C. H. Pettit, 262 West Thirty-fifth street, New York, makes a specialty of plumbers' wood work. In addition to a variety of closet seats, bath rims and washtub covers he makes to order whatever may be required for special cases in any kind of wood.

At a recent meeting of the Master Plumbers' Association of Memphis, Tenn., resolutions of respect and sympathy were passed, and ordered sent to the family of J. W. X. Browne, an esteemed member who recently died.

Wm. H. Raley & Co. is the name of a new firm of plumbers and tinsmiths, located at 604 Washington street, Lynn, Mass.

John Apgar is erecting a store for R. Giles on Main street, Plainfield, N. J., where Mr. Giles will carry on the plumbing business.

Geo. R. Pasco, 274 Columbus avenue, New York, speaks highly of the smoke test as an aid to the sanitary engineer and plumber. He is now occupied in remodeling a number of plumbing systems whose defects were discovered by the smoke test.

The many friends of Thomas C. Knight of the Henry McShane Mfg. Company, 50 and 52 Myrtle avenue,

Brooklyn, N. Y., will be glad to learn that, notwithstanding the reports in the daily papers of his having been drowned in the storm last week, he is still dispensing plumbers' goods at the old stand.

C. H. Muckenhim of the South Lyon Mfg. Company of South Lyon, Mich., manufacturers of plumbers' wood work, in a recent visit to New York established an Eastern agency with Du Bois & Darrow, 61 Gold street, who are also Eastern agents for the Utopia Water Closets made by Park-McKay Company, Detroit, Mich.

J. A. Fairbanks & Co., the new plumbing firm, at Brewer, Maine, are doing the plumbing in the new addition that is being made to a building by A. C. Kavanaugh on Wilson street.

The Board of Examiners of Plumbers of Watertown, Mass., at their last meeting examined five candidates, and all passed. They were W. J. Murphy, John C. Clark and M. T. Burke as master plumbers, and John W. A'Hearn and Herbert Goding as journeymen plumbers.

W. Z. Evans, Delaware, Ohio, has sold his plumbing business to Pumphrey & Armstrong.

The National Association of Master Plumbers, with present executive offices at 148 Boyleston street, Boston, Mass., Daniel G. Finnerty president, have issued in convenient form "A List of Manufacturers and Jobbers of Plumbers' Material Who are in Harmony with the National Association of Master Plumbers." The little book contains the names of a great many prominent supply houses and manufacturers of plumbers' goods in the United States. The names are arranged alphabetically, so it is an easy matter to refer to any individual firm. At the back of the pamphlet are printed the famous Baltimore resolutions with the amendments up to June 15, 1893.

The Bramhall Deane Company, 262-266 Water street, New York, make a specialty of the manufacture of sterilizing apparatus, many of which are specially adapted for hospital use, and operated by either steam or gas and some by a lamp. They are devised for sterilizing the instruments used by surgeons and the bandages and dressings used in operations. Another apparatus is used for sterilizing or disinfecting the clothing of patients admitted to hospitals. The water sterilizer, which has been illustrated in our columns, is designed to furnish water for either drinking, cooking or surgical purposes. These goods open a new field for the plumber in his sanitary work, as the larger apparatus require either lead or iron pipe for their connections. The hospitals of Atlanta, Ga.; Elizabeth, N. J.; New Haven, Conn.; Boston, Mass., are equipped with these apparatus. The Kings County Hospital, at Flatbush, and the German, Presbyterian and Roosevelt Hospitals and the Eye and Ear Infirmary in New York are some of the other institutions in which these sterilizing apparatus have been used with satisfactory results.

In response to the advertisements of the Board of Education of Newark, N. J., for bids for the plumbing and steam heating repairs for the next year, two bids were received that have attracted some attention both in and out of the trade. One bidder offered to furnish journeymen at $2.20 and helpers at 50 cents per day, and another at $2.50 and 75 cents respectively. The ruling prices in Newark for good workmen are 60 cents an hour for plumber and helper, and 70 cents an hour for steam fitter and helper, and the discrepancy has excited some adverse criticism on the plumbers and steam fitters. The Master Plumbers' Association of Newark held a special meeting to consider the matter and a committee has been appointed to see the low bidders and get an explanation.

John Delehanty.

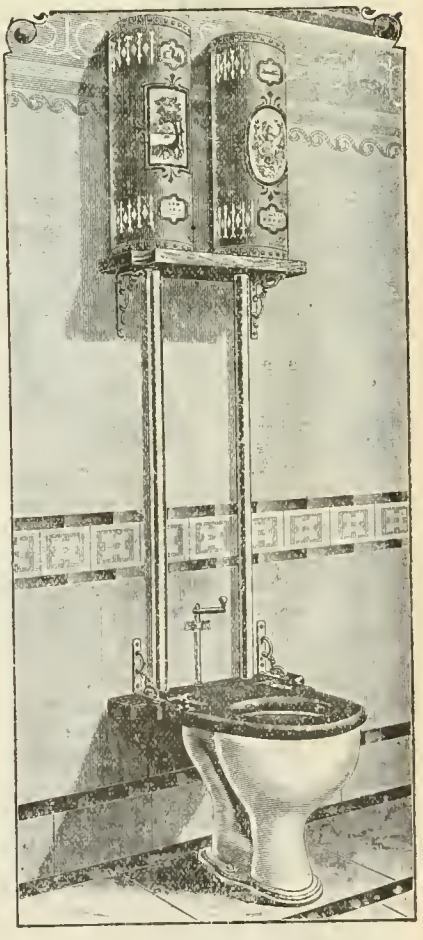
The students who have been through the plumbing course of the New York Trade Schools are all interested in John

John Delehanty.

Delehanty, whose portrait is given here. Mr. Delehanty was born in 1860, and as a youth was bookkeeper in the plumbing establishment of I. O. Shumway until he left to serve a regular apprenticeship at the plumbing trade with another New York plumber, Wm. Foster. In 1890 he started an establishment, and is now interested in two shops under the firm name of Delehanty & Roach, one at 906 Columbus avenue, the other at 679 Second avenue. For the past two seasons he has held his present position, having been selected by the Trade School Committee of the Master Plumbers' Association of New York, of which association he is a member. In addition to the knowledge and skill he has acquired from experience, Mr. Delehanty has a fund of information gained from reading and studying plumbing literature and problems. Another invaluable qualification for his position is best explained by an observation of the wag of this year's class: "I have learned about all I want to know except whether or not Delehanty has a temper." Having had 144 pupils in the day class this year, 114 were graduated, and instruction given to two night classes of 79 and 74 respectively. In his work he was ably assisted by a well qualified corps of instructors. John McMenomy has been a plumber over 40 years and Rufus A. Clarke is another apprentice of the fifties. Thomas Kelly has given talks on modern plumbing before the journeymen's union. Thomas B. Walmsley, who learned his trade in England, has worked in South Africa, and for the past ten years in New York, was the instructor of the lead burning classes which made such a fine showing this year. George B. Woods and James J. Lynch are two other instructors, whose services were necessary on account of the size of the classes.

The Kelly Double Tank Water Closet.

The water closet which is herewith illustrated is the latest production of Thomas Kelly & Bros., 124 Franklin street, Chicago. The closet bowl used is of the syphon jet pattern. The two tanks and two valves are independent of each other, the valves being located below and at the rear of the seat. The operation of the closet is as follows: One of the air tight tanks fills with water while the other is empty, and by turning the handle shown above the seat, a valve is opened and the tank that is filled discharges its contents into the closet bowl. The operation of turning the crank opens the valve connected with the empty tank, which fills as far as the pressure of water can compress the air. The bowl contains a large quantity of water, which is forced out by the jet from tank. There are no movable parts in either tank or closet bowl, the only movable parts in connection with them being the valve pistons and the handle for operating them. Among the points of advantage claimed are the absence of noise and the impossibility of overflow; waste of water is also prevented. Either one or the other of the tanks acts as an air chamber at all times. There being such a large air chamber, the tendency is to prevent bursting of pipes and water hammer when used in a house of ordinary size. The claim is made that any objection that may be



The Kelly Double Tank Water Closet.

entertained regarding the use of syphon jet closets on account of the difficulty of giving open tanks sufficient elevation to produce the desired water pressure is overcome by the use of the double air tight tanks.

STOVE TRADE NOTES.

The Stove Convention.

Some changes have been inaugurated in connection with the annual convention of the National Association of Stove Manufacturers, to be held in Chicago next month, which it is expected will add materially to the interest and value of the meeting. Heretofore committees have had in charge the work of presenting reports or papers covering certain subjects relating to the business of stove manufacture, these papers being read at the sessions and discussion invited from the members present. The impression seems to have gained force in the minds of some of the members that greater good would result by slightly changing the method of procedure, and this year a new plan has been adopted. Invitations have been extended to various manufacturing concerns in the membership of the association to prepare papers on the subjects which were enumerated in our columns March 31, and in every instance we understand the invitation has been accepted. The topics announced cover a sufficiently wide range to draw out remarks from all present and evoke a lively discussion, which should tend to awaken increased interest in the proceedings of the national body. With a view to facilitating the business of the convention there will be no adjournment dividing the morning and afternoon sessions, but a short recess will be taken in the middle of the day, when a cold collation will be served in the assembly room. By this means members will be enabled to follow the progress of the discussion on any subject without serious interruption, and at the same time more satisfactory results will be accomplished. Judging from the circular lately issued by Secretary Thomas, the meeting should prove a most interesting and important one.

The Dippo Mfg Company of Cleveland and Chagrin Falls, Ohio, are making rapid progress in the manufacture of the Ferrosteel ranges, reference to which was made in these columns not long since. Mr. Dippo, who has been practically connected with stove making since boyhood, is very enthusiatic over the new mixture known as "Ferrosteel," which name has been adopted for both the metal and the productions of the company. The latest move upon the part of the company has been to secure W. M. Powell as vice-president and manager of the sales department, with headquarters in Cleveland. Mr. Powell is well known from his long connection with the management of the stove department of the James Smart Mfg. Company of Brockville, Canada.

Cupola Management.*—X.

BY DR. EDWARD KIRK.

Dumping.

As soon as the molders are through pouring their work, if there is no iron to be melted for other purposes, preparations are at once made for dumping the refuse from the cupola. The blast is first shut off by stopping the blower and the tuyere doors are at once opened to prevent the escape of gas from the cupola into the blast pipe, where it might do much harm. The melted iron in the cupola is then drawn off by the cupola men and poured in the pig bed. If there is a lot of small iron in the cupola that has not been melted time is given it to melt to save picking it out of the dump, but if there is a lot of pig or other heavy iron unmelted it is let fall with the dump and the bottom is dropped as soon as the melted iron is drawn off.

The small props supporting the bottom are first removed and laid away. The main prop is then removed by striking it with a long bar at the top or pulling with a hooked bar at the bottom, and the instant it falls the doors drop. When the doors of a large cupola drop, the sand bottom and a greater part of the refuse of melting falls with them and a sheet of flame and dust instantly shoots out ten feet or more from the bottom of the cupola in all directions. But the flame disappears in an instant and the dust settles, revealing the white hot dump in a heap under the cupola. The cupola men then throw a few buckets of water on it to chill the surface and deaden the heat, and the melter puts a long bar into the tuyeres and tries to dislodge any refuse that may be hanging to the lining while it is hot. Small cupolas do not dump so freely, and the sand bottom has frequently to be started with a bar after the door drops. A long bar must be used for this purpose and the melter must be on his guard, for the dump may fall as free as from a large cupola the instant it is started and a sheet of flame shoots out.

Small cupolas frequently bridge over above the tuyeres, and only the sand bottom and refuse below the bridge is dumped when the door falls. The aim of the melter is then to break away the bridge or get a hole through it, so the cupola will cool off in time to be made ready for the next heat. He puts a bar in at the tuyeres and breaks away small pieces at a time, and if there is not a large body of refuse in the cupola, a few short pieces of pig are thrown in from the charging door, so they will strike in the center and break through the bridge. This bridging and hanging up of the refuse in a cupola when only run for a few hours is entirely due to mismanagement, for any cupola, no matter how small it may be, can be run for six or eight hours without bridging and be dumped clean if properly worked.

When the dump falls from a cupola it is a semi fluid mass of iron, slag, cinder, dirt and fuel. This mass falls in a heap under the cupola, and if scattered or broken up when very hot it is more readily wet down and more easily removed when cold. In some foundries a heavy iron hook or frame is placed under the cupola before dumping and is withdrawn with a chain and windlass after the dump has fallen upon it and been partially cooled with water to harden it so the hook will not slip through it without breaking it up and scattering it. In other foundries it is scattered with a long rake or hook worked by hand. In pipe foundries two or three short lengths of condemned pipe are placed under the cupola before dumping, and the dump is broken up by running a bar into the pipe and lifting them up after the dump has been slightly cooled. But in a great many foundries where the dump is small or where there is plenty of room to remove it when cold it is let lie as it falls and is wet down by the cupola men, or a few buckets of water are thrown on by the cupola men to deaden it, and it is left for the watchman to wet down during the night. Care must be taken to not put on too much water or the floor under the cupola will be made so wet there will be danger of the dump exploding when it falls upon it the next heat.

Removing the Dump.

A number of plans have been devised for removing the dump from under the cupola. Iron cars or trucks have been constructed to run under the cupola and receive the dump as it falls, but they cannot be used unless there is sufficient room for the doors to swing clear of the car, and few cupolas are so constructed. The dump must be removed from the car when hot to avoid heating and injuring the car, and considerable room is required for handling the car after it is taken from under the cupola. For these reasons cars are seldom used. Iron crates have been made to set under the cupola and receive the dump and be swung out with the crane, but they get fast under the cupola and soon are broken, and it is almost as much work to handle the dump from the crate as it is from under the cupola. A number of other plans have been tried, but the dump must be picked over by hand, and it is as cheap to pick it over at the cupola and remove it in wheelbarrows as any way that has yet been devised. The dump is broken up with sledge and bar when cold and picked over. The large pieces of iron are picked out and thrown in a pile for remelting. The coke is thrown in a pile to be taken to the scaffold or core oven furnace. Anthracite coal that has passed through a cupola and been subjected to a high heat will not burn alone in a stove or core oven furnace, and it is very doubtful if it produces any heat when mixed with other coal and again put in the cupola, and only the large pieces are picked out, if any.

The cinder, slag and other refuse are shoveled into a wheelbarrow and taken to the rattle barrels or dump. If the sand bottom is to be used over again it is riddled out in a pile and wetted.

*Copyrighted, 1894, by Edward Kirk.

If not, it is removed with the cinder and slag. As soon as the bulk of the dump is removed the melter goes into the cupola and breaks down the ring of cinder over the tuyeres and chips off any that may be adhering to other parts of the lining. The dump is then all removed and the floor around the cupola is cleaned up preparatory to daubing up. Nothing is done with the dump after it is taken from the cupola but to recover the iron from it. This is done in two ways, by picking it over or milling it. The iron is often of the same color as the dump, and so mixed with it that it is almost impossible to recover it all by picking unless a great deal of time and pains is taken; and it is cheaper to throw out only the pieces of pig and shovel all the remainder into the tumbling barrels, where it is separated in a short time and all the iron recovered that is worth recovering.

Chipping Out.

Before going into the cupola to chip it out the melter slushes one or two buckets of water around the lining from the charging door to lay the dust. He then goes in from the bottom if he can get in, but if the cupola is so badly bridged he cannot get up into it he takes a long bar and endeavors to break down the bridge from the charging door, or goes down into it from the charging door, and with a heavy bar or sledge breaks it down. As soon as he gets a hole through large enough to work in he goes down through it and with a sledge or heavy pick breaks down the shelf of slag and cinder that always projects from the lining over the tuyeres. He then takes a sharp pick and trims off all projecting lumps of cinder and slag and gives the lining the proper shape for daubing up. It is not necessary or advisable to chip off all the cinder and inherent matter down to the brick, for the cinder stands the heat equally as well as new daubing, and in some cases better. But all soft honeycombed cinder should be chipped off and all projections of hard cinder that are likely to interfere with the melting or tend to cause bridging should be removed.

Some melters have a theory that to prevent iron running into the tuyeres they must have a projection or hump on the lining over the tuyeres, and they let the cinder build out from 3 to 6 inches thick and 6 to 12 inches deep at the base. These humps tend rather to throw iron into the tuyere than to keep it out, for the fuel becomes dead under the hump and the iron in its descent strikes the hump and follows it around into the tuyere. They also form a nucleus for bridging. The refuse of melting as it settles lodges upon these humps and is chilled by the blast. A small cupola with these humps over the tuyeres will not work free for more than an hour, while the same cupola with the humps removed and the lining straight would work free for two hours and dump clean. They also interfere with the melting and cause bridging in large cupolas All humps that form on the lining above the melting point from bad charging or other causes should be removed, for they hang up the stock and retard melting.

The cupola picks generally used are entirely too light for the work to be done with them and the handles are not firm enough. When the melter strikes a blow he cannot give the pick force enough to cut away the point desired and the handle gives in the eye so the pick glances off and cannot be held to the work. Repeated blows with a light pick turn the edge and renders the pick worthless and the melter has to do two or three times the work really necessary in chipping out the cupola, and then he does not get it right. What the melter wants is a heavy pick with a firm handle. Then he can hold the pick where he strikes and prevent it glancing off. He can strike a blow that will cut away the cinder at one stroke and not jar and injure the lining nearly as much as he would by repeated blows with a light dull pick. The melter should be provided with three picks made of the best steel, weighing 4, 6 and 8 pounds each. They should be furnished with iron handles solidly riveted in, or should be made with large eyes for strong wood handles. The picks should be dressed, tempered and ground as often as they get the least bit dull.

Columbian-Garland Range.

The Michigan Stove Company of Detroit, Chicago, Buffalo and New York City have just issued a fine catalogue of their new line of wrought steel ranges brought out under the name of Columbian Garland. The catalogue is a handsome specimen of the engraver's art and the printer's skill. It is 8 x 10 inches in size, and only contains 16 pages and is bound in a paper cover, but on these comparatively few pages has evidently been concentrated an unusual amount of book making taste and experience. The cover is illuminated with richly embossed gold lettering. A silken cord ties the leaves together. The body of the ink used in the book is black, but it is relieved by an occasional crimson line, which is by no means out of place, but very tasteful. The engravings are half tones of remarkable sharpness, which bring out the special features of the range with excellent effect.

The Columbian-Garland range is described in this catalogue as of moderate price, but strong, durable and desirable in every way, and possessing all the advantages of higher priced goods. Three styles of grates are furnished—the duplex for hard coal, a very heavy flat shaking and dumping grate for soft coal, and a special wood grate. All these grates and their frames pull out and can be instantly changed or replaced without disturbing the bed plate or fire box linings. The ash pan is unusually large, and guards are provided which throw all the ashes into the pan. The draft is not only admitted through the ash pit door in front, but also through slides at the end of the range to the full length of the fire box. The oven is "aërated" like the ovens of other Garland cooking stoves and ranges. The entire oven can be drawn out by simply turning four buttons, thus giving access to all flues. The oven door is of steel, smooth on the inside, and when open it answers for a shelf, being counterbalanced with a weight and spring. A pedal attachment can be used both to open and shut the door. The top of the range is made up of pans or key plates, having two kettle holes in each. The front pan has a loose center, which is practically indestructible. Two or more ranges of this line can be placed together and connected to make a continuous range, with one fire box for each oven.

The illustrations show first the Columbian-Garland range, with low closet and in square form, made in six sizes; next, with high shelf and low closet, in six sizes; third, with high shelf, low closet and a 15-gallon copper reservoir on brackets at the side, also in six sizes; fourth, with high shelf, low closet and broiler on brackets at the side, also in six sizes; fifth, with high and low closet and square form, in six sizes; sixth, with high shelf, low closet, and connected with hot water boiler; seventh, with double oven, high shelf and low closets.

ODD PLATES.

The Harvey Furnace Company, at 1325 Broadway, New York, make their Vim furnaces and ranges a specialty and find a regular demand for heating with hot air.

The F. E. Belden Mica Mining Company, 12 Broad street, Boston, Mass., are putting on the market New Hampshire mica, for which they claim particular clearness and fine rift. It is put up in pound packages in convenient form for the stove trade.

The Thatcher Furnace Company, 33 Peck Slip street, New York, manufacturers of the Thatcher and Scorcher furnaces and the Champion steam and hot water apparatus, are making some necessary changes in their manufacturing plant at Newark, N. J. They are putting up a substantial and capacious brick building for storing their patterns and are making a large four-story addition to their foundry building.

The Rocket, Columbus and Servia ranges, made by Southard, Robertson & Co., Peck slip and Water street, New York, are now conspicuously displayed for the consideration of the buyers of summer goods. A novel sign is displayed over their new Waldorf range. Letters spelling the word have been sawed out of 1-inch white pine and mounted on black walnut and varnished.

The New York office at 244 Water street of the Raymond & Campbell Mfg. Company, Middletown, Pa., is preparing for the summer trade in ranges by receiving two carloads of Anna, Capital, Model, Perfect and Grand Perfect ranges.

J. Snyder of the Thomas, Roberts, Stevenson Company, Philadelphia, spent the week at their New York house at 250 Water street, in the interest of the Gauze Door and Fortune line of stoves and ranges.

The Warren Hardware Company of Warren, Ohio propose to erect a plant for the manufacture of steel ranges. They announce that under no circumstances will they accept from the citizens of Warren any contributions or bonus to influence the location of the plant. Some movement of that kind was started because of the rumor that other towns were bidding for the new works.

The works of the Electric Oil Stove Company, Homer, Mich., are the subject of an illustrated notice in a late issue of the Homer *Index*, published every Wednesday at the place named. From this article we learn that the proprietor and general manager of the works, Benjamin R. Goodrich, went to Homer about 19 years ago with a capital of less than $1000 and embarked in the hardware business. Gaining more than an average degree of success, he retired in 1885, accepting a position as traveling salesman for the Detroit White Lead Works, continuing with the company for about two years. In 1888 he commenced business as a manufacturer,

having invented a self heating folding bathtub with automatic connecting waste tube. In 1890 he invented an oil heating stove, and disposing of his bathtub rights, turned his attention to the manufacture of oil stoves. The works of his company are well equipped with the necessary machinery for carrying on the business, but it is the intention to soon install a new engine of more than double the horse power of the present one. One of the buildings is devoted to the grinding, polishing and nickel plating departments, another to the mounting and crating rooms, tin shop, &c., while a third is occupied as a testing room and paint shop. The office occupies a one-story building, which is separated from the others. According to the article referred to there were in the first year of the company's existence upward of 7000 heating stoves manufactured and sold, while in 1890 the output was 11,000 heaters and 6000 ranges, and in 1892 there were 13,000 heaters and 14,000 ranges and lamp stoves turned out. The works give employment to a force of hands ranging from 20 to 80, according to requirements. R. E. Goodrich assists in the general management; A. E. Knight has charge of the shipping department; Charles Gardner is inspector of castings, and James Merrett is foreman of the shops.

The Danville Stove & Mfg. Company of Danville, Pa., will bring out this season, under the name Ideal, a line of square heaters, comprising four sizes, handsomely nickeled and ornamented, and designed to meet the demand for high class medium priced goods Their line of ranges will be augmented by the addition of the Beaver, a new six hole construction of moderate price, with solid or portable hearth, hopper or pouch feed, adapted to all kinds of fuel, duplex or triplex grate, with or without shelf, handsome nickel bracket and band, and large ash pit. The new range will also be made embodying a patented device for heating an upper room. The company are also improving the line of Beaver furnaces and redressing their line of Queen Beaver ranges. They report a satisfactory business for last season, notwithstanding the dull times, and the close of the season found them with very little stock on hand. They are this season, in addition to their own lines, pushing sales of Monarch gasoline goods, for which they are agents for New England, New York, New Jersey and Pennsylvania.

The Fuller & Warren Company, Troy, N. Y., issue advertising cards calling attention to the fact that house heating with hot air furnaces and hot water boilers is at present attracting considerable attention and add that their F. & W. Co. furnaces produce excellent results. They invite the trade to send for their illustrated catalogue.

J. H. Cort & Sons, Beekman and Water streets, New York, are fitting the kitchens of the St. Lawrence apartment house, at Eighty-eighth street and Madison avenue, with gas ranges. Their Cort gas range, with high shelf and canopy, is the only cooking apparatus used. Hot water is furnished from an apparatus in the basement. Their ranges have been used in the Carrollton, Pontiac and Palacio apartment houses with general satisfaction.

We are indebted to the Magee Furnace Company of Boston, Mass., for a neat little folder announcing that within the past three months the patterns for the Boston heater have all been made over and many valuable improvements introduced. It is also stated that the company are using heavier plate iron in the construction than ever before. The Magee Boston is well known from Maine to California, and in the little folder which the company have issued are set forth some of the claims made for it. We also have from the company a circular recently issued by E P. Carpenter Company of Pawtucket, R. I., which is in the nature of an advertisement of the Magee Grand range. This stove has proven exceedingly popular with the trade in the territory covered by Messrs. Carpenter, and during the fall season of 1893 they sold 173 Magee Grand ranges, a record which it is claimed was never before made in the same time by any dealer in New England. The circular gives a list of the names and addresses of the purchasers. This shows what enterprise and push can accomplish in the sale of goods possessing superior features of construction and operation.

The Littlefield Stove Company of Albany, N. Y., send us a copy of a pamphlet which contains some new matter relative to the West Shore range. It is entitled: "Fifty-nine Years' Experience from the James or Saddlebag Stove to the West Shore Range for 1894." The opening pages describe the important inventions incorporated in the West Shore range, following which are particulars gleaned from the records of the Patent Office and designed to show the difference between the West Shore and other ranges. A feature of the pamphlet is the directions for setting up and starting a fire in the West Shore range and the size of coal which should be used. The pamphlet is profusely illustrated and shows the range named in numerous styles and sizes. Mr. Littlefield states that the pamphlet contains "the truth, the whole truth and nothing but the truth; therefore it will be of value to studious readers."

The Peninsular Stove Company of Detroit, Mich., are distributing some very pretty decorated cards of a size to be easily carried in the pocket, and which are intended for advertising the Peninsular stoves and ranges. The cards constitute the first installment of the company's stock of advertising matter which is being prepared for dealers handling Peninsular goods. The side of the card carrying the ornamental design has in the upper right hand corner a chocolate colored panel containing six words, as follows: "Quick bakers; superior cookers; powerful heaters." In the lower left hand corner is a *facsimile* of the company's trade-mark.

William Kerby, 4 and 6 Peck slip, the New York representative of I. A. Sheppard & Co., Philadelphia, is showing a seasonable attachment to the Royal Fidelity range. It is a cross piece to which two gas burners are attached which takes the place of the regular cross piece and supplies a flame under both of the cooking holes of the fire chamber. A cock for each burner is provided and an attachment for connecting a hose to supply the gas. It can be applied and used by any one. Those ranges which have an upper warming shelf can be supplied with gas burners attached to the shelves.

Gas and gasoline stoves and summer ranges, under the name Manhattan, are now attractively displayed by Eugene Munsell & Co., 218 Water street, New York. They also make a specialty of supplying mica for all purposes, and to meet the requirements of stove manufacturers they are prepared to furnish first-class mica in any desired size and quantity. For the smaller dealers packages of various quantities, containing an assortment of convenient sizes, are prepared.

Hansell & Belson have leased the showroom and warehouse at 144 North Second street, Philadelphia, and will enter into the wholesale stove business, representing Chas. Noble & Co. in the vicinity of Philadelphia. They will also represent some leading refrigerator, gasoline, oil and gas stove manufacturers, and will carry a full line of supplies for the stove trade.

A. B. Fisher, 387 Kent avenue, Brooklyn, N. Y., is just completing patterns for an entirely new gas regulator or air mixer for gas stoves. Mr. Fisher makes an extensive line of gas stove faucets and air mixers.

Reports from Chattanooga, Tenn., are to the effect that the capacity of the works of the Southern Queen Range Company, located in that place, is to be doubled.

The Wilcox Heat-Light Company, Grand Rapids, Mich., have issued from the press a 16 page pamphlet, bound in straw colored covers, and relating to the line of oil heating stoves which they manufacture. The assortment includes the Model oil heater, made in several sizes, the Challenge, the Eclipse and the Standard. The company state that for this season they have added several new styles and have made a number of important improvements. The Model gas radiator is one of their specialties and possesses features which render it powerful in operation. A point to which attention is invited is the presence of a water pan under the burner. The water fount is made of heavy cast iron, enameled, and is claimed to be peculiar to this radiator.

At a meeting of the Warren Hardware Company, held Saturday, April 7, it was decided to commence work on the new buildings as soon as possible. The main structure will be about 40 x 150 feet in size, and it is expected to have the plant in running order the latter part of May. When the new works are completed the company will employ from 25 to 50 men and will turn out about 20 ranges a day.

Hart & Crouse of Utica, N. Y., have leased the store 79 Lake street, Chicago, Ill., where they will carry a full line of Royal heaters for hot water, steam, hot air and combination. The firm will take possession of their new quarters on May 1 and the management will be in the hands of George L. Rood, who will at all times be ready to show the goods and furnish estimates for heating.

The Fox Furnace Company, 28 Vincent street, Cleveland, Ohio, have issued an attractive catalogue relating to warm air furnaces. It consists of 30 pages of letterpress bound in colored paper colors, and presents a great deal of information and value to dealers handling goods of the character named. The opening pages show how the joints in the Fox furnaces are made to render them perfectly tight and also illustrate and describe the grate, dust flue and fire pot which the company use. The Fox furnace is offered in a variety of styles and sizes, tables being given showing prices and dimensions. A list of testimonial letters from various in-

dividuals and concerns indicate in some measure the satisfaction which the heaters have given to users of them.

THE CHICAGO & ERIE STOVE COMPANY favor us with an illustrated circular of the Erie gasoline stove which they have just placed upon the market. The stove is made in several sizes, is simple in the arrangement of its parts, and is provided with a single generator. The burners are sawed on the side, rendering them, the makers claim, very economical, because they spread the flames into thin sheets, securing a large amount of heat in proportion to the quantity of fuel consumed. The cast top is of ample proportions, with a space between the burners. The independent burner is made on the same general plan as those described in connection with the single generator. Nos. 20 and 120 are made with a single generator for two burners, while Nos. 30 and 130 have three burners. The No. 1 Erie has one independent generator; Nos. 2 and 12 have two independent generators, and Nos. 3 and 13 have three independent generators. The manufacturers state that the tank has an inside arrangement to expel the air from the pipes when first lighted, making a quick flow of gasoline to the burners.

F. & L. KAHN & BROS., Hamilton, Ohio, send us circulars illustrating and describing the I X L Family Peerless gas stoves, which embody many interesting features. The roaster and broiler are situated below the top and are of sufficient capacity to meet all ordinary requirements. Baking is done in the oven above the top, the oven having a drop door which makes a shelf when opened. The burners have removable covers and adjustable air mixers. These goods are shown in several varieties, as are also the I X L table stoves with one, two and three burners. A second circular relates to the Waldorf broiler and roaster for any kind of gas. This is claimed to be the latest and most efficient broiler and roaster for hotels, restaurants and large families. The doors when opened stand flush against the right and left ends of the broiler and out of the way. Attention is also invited to the Bijou Junior, a four-burner all cast hot plate, and to the Corker, shown with one, two and three burners.

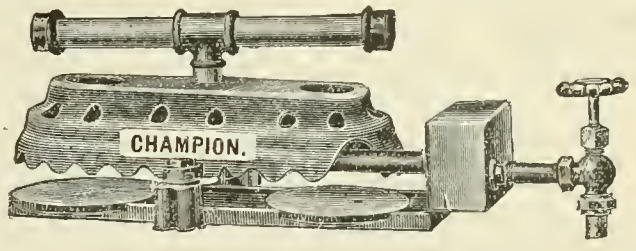
E. C. HANRAHAN has been appointed Western manager of the Peninsular Stove Company, in immediate charge of the company's branch house at 79 and 81 Wabash avenue, Chicago. Mr. Hanrahan has been connected with the company for about a year. He was previously located at St. Louis, where he conducted a stove jobbing business. Mr. Hanrahan is well acquainted with the Western stove trade and is thoroughly conversant with all the details of the stove business.

A FOUR-PAGE CIRCULAR which is received bears the inscription: "A Few References from Parties Using Richardson & Boynton Company's Warm Air Furnaces Erected by the Canfield Stove Company, 166 Strand and 19 Ferry street, Rondout, N. Y." The testimonial letters are from various sections of New York State, and indicate in a very forcible manner the estimation in which the goods named are held by those who have practically demonstrated their merits.

WILLIAM J. H. GLUCK of Baltimore, Md., is sending out a little pamphlet illustrating the Reliance and Reliance Safety gasoline stoves, which are made in several styles and sizes. These goods are finely japanned and ornamented, and are provided with safety Reliance tanks. The burners are the Reliance individual burner No. 2, operated with nickeled wheel blunt valves, so that the flames can be turned down low.

Champion Oil Burner.

In the accompanying illustration we present a general view of the Champion oil burner, which is being offered the trade by the National Oil Burner Company of Cleveland, Ohio. The burner and valves, which represent the result of years of experimentation, are covered by United States patents granted last year. In operation it is simply necessary to place the burner on the grate of the cook stove or range in connection with which it is employed, drill a ⅝-inch hole in the stove door, or put on a sheet iron door, and connect the pipe and valve to the burner. The oil tank may be placed on a bracket against the wall near the stove, or it may be placed outside of the house, as most convenient. The burner for use in connection with heating stoves is placed in position in the same general manner as described above. The manufacturers claim the burner will not smoke or carbonize and can be used without odor or noise. It is made strong and durable, and the company say they will replace any burners showing flaws or defects within one year. They use a special rolled lead pipe for the purpose of conveying the oil from the tank to the burner. The oil tank is made of heavy galvanized iron.



Champion Oil Burner

Camden, N. J., is to have gas at $1.25 per 1000. The gas company having improved their plant, continue their enterprise by offering their gas at a much reduced rate.

Advices from Springfield, Mass., state that 300 of the new Krag-Jorgensen rifles have been completed and are about to be sent to the War Department. Samples of the new gun have been sent to the Governors of the different States, and one of the new guns was sent on Tuesday to the German Emperor. Samples are also to be sent to the officers of the departments in the United States Army. The Fourth United States Infantry will be the first regiment equipped with the new piece.

The Central New Jersey Traction Company have been incorporated at Trenton, N. J., to carry out a scheme for connecting New York and Philadelphia by trolley. A supplementary charter is being obtained in Pennsylvania for a line from Philadelphia to Trenton. Construction of the trolley lines between Paterson and Orange and Trenton and Kingston is, it is stated, to be begun at an early date.

SCRAP.

IMPORTS of tin and terne plates into the United States during the first eight months of the present fiscal year were of the value of $7,883,304. In the corresponding period ended February 28, 1893, the value of tin plates imported was $10,304,543.

MARSHALL BROS. & Co. of Philadelphia report a fair volume of business for the past month. They are exceedingly busy in their black plate department, consequent upon the increased demand for American tin plate.

HENRY W. SCATTERGOOD, proprietor of the Black Diamond Tin Plate Works, Laurel street, Philadelphia, reports an improvement in the demand for his products. His brands are the Black Diamond, an extra coated roofing plate; Quaker City, Horse Shoe, Arrow and Laurel.

HUGHES & PATTERSON of Philadelphia have closed down their tinning plant, having a stock of plates on hand sufficient for the present requirements of their trade.

GOV. ROBERT E. PATTISON of Pennsylvania was a visitor in New Castle, Pa., last week, and while there visited a number of industrial establishments. The Governor seemed to be particularly impressed with what he saw at the plant of the New Castle Steel & Tin Plate Company. In this establishment he witnessed the operation of making tin and terne plate from the billet to the finished plate, or more properly speaking, from the ore to the finished plate, as the billets are obtained from the Shenango Valley Steel Company, whose plant is located adjacent to that of the New Castle Steel & Tin Plate Company. The pig iron used by the Shenango Valley Steel Company is made by themselves, so that it can be truthfully said that the Governor saw tin and terne plate made from the ore to the finished material.

THE REPORT of Gummey, Spering & Co., Philadelphia, Pa., to Special Agent Ira Ayer of the Treasury Department, respecting their output of tin plates for the quarter ending March 31, 1894, gives the following figures:

Total make tin and terne	1,116,330
Tin plates	214,296
Terne plates	902,034
American black plates	898,431
Foreign plates	217,899
Tin under 63 lbs. per 100 square feet	213,453

Terne plate all under 63 lbs.

The firm of Gummey, Spering & Co. began making plates early in 1892, and have not stopped except a few days for repairs since then. A particularly gratifying fact in the above report is the great amount of American black plates, more than three-quarters of the total product being of American origin and only 218,000 pounds of foreign plates.

TRADE REPORT.

The Iron Market.

The intimations of an improving market made last week appear to have been confirmed by recent developments. A considerable amount of business has been placed, and there are very few furnaces or mills that have not made substantial additions to their order books. There is also quite a good deal of business under negotiation, and while prices show little or no improvement, the sentiment is more hopeful than it has been for many weeks past. The increase in the output of Pig Iron concurrently with a decrease in stocks is a significant feature, and is not without influence on those who closely watch the course of events. No great advance is looked for, but it is expected that the next two or three weeks will show that the corner has been turned, and the building up process fairly commenced.

Pig Iron.—As yet no intimations have come to sales agents of Southern furnaces in the New York district to withdraw from the market as the result of the troubles in the Birmingham coal mines. On the contrary, prices lower than ever have been made during the last week. Sales of Western Pennsylvania Irons are being pushed in this territory, and it is reported that they are going right into the foundries in the Lehigh Valley. One point which is attracting some attention among sellers is the rapid decline during the past year in the proportion of No. 1 Iron which founders are using in their mixtures. Some of them have learned to get along without it altogether. We quote standard brands $12.50 @ $13.25 for No. 1; $11.50 @ $12.25 for No. 2, at tidewater. Southern Iron, same delivery, $12 @ $12.50 for No. 1; $11 @ $11.50 for No. 2; $10.50 @ $11 for No. 3; $10.75 @ $11.25 for No. 2 Soft, and $11.25 @ $11.50 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $10.25 @ $10.50.

In the Philadelphia district a better demand for Pig Iron is reported, and for nearly all grades of the metal, but prices are quite irregular. The only way to get an exact quotation is to name brand, quantity, delivery and terms of settlement, and as these vary, prices vary. The quotations given below fairly indicate the range of quotations in Philadelphia and vicinity, although at Harrisburg, York and Susquehanna Valley points 25¢ @ 40¢ less has been accepted owing to advantages in freights, &c., but even then there is frequently a wide disparity in quotations.

Standard No. 1 Foundry X	$12 50	@	$11.85
Standard No. 2 Foundry X	11.75	@	12 25
No. 2 Plain	10 75	@	11.00
No. 1 Soft	11.00	@	11.50
No. 2 Soft	10.50	@	10 75

A large number of sales of Bessemer Pig have been made during the month in the Pittsburgh district to Eastern mills, while a considerable tonnage for speculative purposes has also been closed, the whole aggregating some 100,000 tons. There is no change in the situation of Foundry Iron, which continues in light demand with prices ruling very low. Quotations are given as follows:

No. 1 Foundry	$11.00	@	$11.25,	cash.
No. 2 Foundry	10.25	@	10.50	"
No. 3 Foundry	9.75	@	10.00	"
Bessemer	10.35	@	10.50	"

Transactions in the Chicago market in both local and Southern Coke have been almost wholly confined to small lots. The most important sale last week was one of about 2000 tons of local Iron. The demand for small lots comes from all classes of customers, but the aggregate volume of such business is by no means satisfactory to furnace companies. Consumers are still apprehensive of disturbing influences which may again unfavorably affect prices, and consequently inquiries are unusually light. Very little is doing in Lake Superior Charcoal. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00	@	$15.50
Local Coke Foundry, No. 1	11.25	@	11.50
Local Coke Foundry, No. 2	10.50	@	11.00
Local Coke Foundry, No. 3	10.00	@	10 50
Local Scotch	11.50	@	11.75
Ohio Strong Softeners No. 1	13.00	@	14.00
Southern Silvery, No. 1		@	11.50
Southern Silvery, No. 2		@	11.00
Southern Coke, No. 2	10.00	@	10.35
Southern Coke, No. 3	9.75	@	10.00
Southern, No. 1, Soft	10.25	@	10.50
Southern, No. 2, Soft	9.75	@	10.00
Tennessee Charcoal, No. 1	15.00	@	15.50
Tennessee Charcoal, No. 2	14 50	@	15.00
Alabama Car Wheel	17.85	@	18.00
Jackson County Silvery	15.00	@	16.00
Other Ohio Silvery	13.00	@	13.50

Advices from Southern markets indicate that there has been a fair volume of business in Coke Pig Iron during the week, but not much movement in other kinds. Prices as a rule have been well sustained by the furnaces, which have sold mainly at delivered prices and therefore buyers in many instances have secured supplies at a lower cost to themselves. The strike or threatened strike among the laborers in the South makes sellers cautious, although it is thought that the difficulties will be adjusted without any great amount of friction. The sales for spot and forward delivery aggregate for the week upward of 15,000 tons and sales have been contracted for the remainder of the year at the same prices as are accepted for spot delivery. The buyers of Iron are mainly stove and agricultural works. The Iron Pipe works are melting considerable Iron but are not purchasing much. The market, as a whole, while not essentially better, is certainly no worse than it has been. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$10.50	@	$10.75
Southern Coke, No. 2	9.25	@	9.50
Southern Coke, No. 3	8.75	@	9.00
Ohio Soft Stone Coal, No. 1	14.50	@	15.50
Ohio Soft Stone Coal, No. 2	14.25	@	14.50
Lake Superior Coke, No. 1	13.00	@	13.50
Lake Superior Coke, No. 2	12.00	@	12.25
Hanging Rock Charcoal, No. 1	17.00	@	17.50
Hanging Rock Charcoal, No. 2	16.50	@	17.00
Tennessee Charcoal, No. 1	13.00	@	13.50
Tennessee Charcoal, No. 2	12.00	@	12 50
Standard Southern Car Wheel	16.25	@	17.00
Lake Superior Car Wheel and Malleable	16.50	@	17.00

Metal Market.

Pig Tin.—From the prices that ruled at the date of last week's report there has been an advance of about 0.25¢ ℔ lb, 19.75¢ having been realized for 5-ton lots of Straits Tin for delivery before the end of the current month. The rise was due chiefly to strong advices from London on the 16th inst., but facilitated by the fact that the stock in New York is not only moderate but the holdings so scattered that the market is extremely sensitive to London manipulations. Subsequently values here went a fraction lower, for no other visible cause than a reaction in the foreign market, sales being made late in the week at 19.60¢ for spot and 19.55¢ @ 19 60¢ for April delivery. There is little speculation here at present, and hardly any tendency in that direction. The shape of the market is not attractive. Straits shipments during the first half of the month were quite heavy, including 800 tons to Great Britain and America and 475 tons to the Continent, against a total of 775 tons in the corresponding period last year. Consumption is rather below the average for this season of the year. Prices for small parcels are unchanged at a basis of 21¢ @ 21¼¢ ℔ lb.

Copper.—Business on home account has been larger during the past week. Liberal contracts were made with consumers at 9¼¢ for Lake Ingot, deliveries running up to July. Supplies of Montana product have been cut off to some extent by the Great Northern Railroad strike,

but Arizona product has come forward in sufficient quantity to meet the demand and orders for the cheaper varieties of Copper are being filled at old prices, say 9¼¢ @ 9⅜¢ for Electrolytic and 9¢ @ 9¼¢ for ordinary casting brands. The volume of sales to consumers has been moderate. These latter are buying on an exceedingly prudent scale, taking only just as much as they actually need for present use. Retail prices are about at the level of the last few weeks, Lake Ingot ruling at 10½¢ ℔ lb for small lots from store.

Sheet Copper.—The demand for this material has not expanded to any appreciable extent, nor will it be likely to increase until there is more evidence of a resumption of activity in the building trades. Prices, however, hold their own.

Pig Lead.—The market has been very steady at the higher range of prices established last week. Nearly, or quite, 1000 tons have been placed in round lots, at or about 3.45¢, by local brokers, and a number of single carloads were sold at 3.47½¢. Meanwhile, there was some effort to force prices lower, chiefly by one or two local firms, but the effort was fruitless, since other than Eastern buyers not only purchased quite freely, but had brokers on the alert for all Lead offered at less than 3.45¢ for delivery this month or next. The buying during the week has been chiefly for jobbers and consumers. Very few purchases were made for speculative account. Still jobbers report business as being of a tame character, and not up to the standard of a week or two ago. Indeed, the demand during the present month has not borne out the promise of March, when a very fair movement developed after the long months of depression.

Lead Pipe and Sheet.—Orders and inquiries for Lead Pipe and Sheet Lead have fallen off somewhat from the slightly better volume developed in the first part of the month, doubtless due to the return of cold and stormy weather. A better movement is hoped for so soon as settled weather approaches and buildings now in hand are pushed to completion. Stocks in consumers' hands are very light, but purchases do not, as a general rule, extend beyond absolute requirements for present use. Prices are fairly well maintained and collections are reported as good.

Spelter.—There are some signs of a steadier turn to the market. The best evidence of this is that no response is made to requests for firm offers of the poorest Western brands at 3.55¢, delivered here or at common point. The tests made indicate that 3.60¢ is the very bottom price, and that sellers at less than 3.65¢ are the exception. No large transactions have been effected here, but sales of moderate sized lots to galvanizers make a better showing than for some time past. Small quantities of Western from store are quoted by jobbers at about 4¢ @ 4¼¢ ℔ lb. About 50 % of the producing capacity of the country is shut down. Several furnaces have ceased operations since our last report, so that there is every reason to expect that values will not go much, if at all, lower.

Sheet Zinc.—The consumptive demand is of a very perfunctory character. Manufacturers have again put down the price of Sheet Zinc 2 % during the past week, and it is now far below any previously quoted value. Jobbers' price for 600 lb casks is 4½¢: small lots selling from store at 5¢ @ 5¼¢ ℔ lb.

Antimony.—Fair sales have been made and the market is quite steady at about 8¾¢ @ 8⅞¢ for Hallett's, 10¢ @ 10¼¢ for Cookson's, and corresponding prices for minor brands, with a premium of about ⅛¢ on small quantities.

Nickel.—Little change has taken place, purchases being of routine character and fair, all told. Prices range between 40¢ and 45¢, as to size of lot.

Tin Plate.—So far as regards wholesale buying, little if any improvement has been experienced during the week in sales for either prompt or future delivery. Considering the season of the year this market is exceptionally quiet and business below expectations. The majority of canners appear to have secured sufficient material by contracts for future delivery entered into at the beginning of the year, while the remainder may be hanging on until the last moment before placing their orders. Be this as it may, the demand from this class of consumers has been remarkably tame of late. Jobbers report, however, that small orders for spot goods have been sufficient to keep them very fairly busy, although these are almost entirely of the hand to mouth character that has become chronic of late, and their aggregate is hardly up to the spring season average. Roofing Plates show some more animation with the return of the building season. Prices are still uneven and more or less irregular, despite the fact that stocks here are considerably below the average and that foreign manufacturers are seriously considering a further reduction of output to offset the bearing of slow sales. Importations for this year have been comparatively light, while foreign stocks are becoming heavy. This is partly explained by the fact that some importers find it cheaper to carry their stocks in store on the other side than to hold them in bond in this country.

A special cable dispatch to *The Iron Age* dated London, April 18, reports the British Tin Plate market as follows: Tin Plate business has been of very fair volume, but the market shows soft tone. At the quarterly meetings prices ruled in buyer's favor. Fair orders were placed for 10 x 10 Siemens Cokes at 3 pence decline, and for Squares at 3⅛ pence under market quotations. Liverpool quotations for Plates were as follows:

IC Charcoal, Alloway grade	12/ @ 12/6
IC Bessemer Steel, Coke finish	11/3 @ 11/6
IC Siemens " " "	11/6 @ 11/9
IC Coke, B. V. grade, 14 x 20	Nominal.
Charcoal Terne, Dean grade	10/3 @ 10/6

Sheet Iron.—Galvanized Iron is in fair demand, but the volume of business is hardly up to the average, owing to the backwardness of the building industry. Prices are fairly well maintained. The demand for Black Sheets is usually light at this season, but at the present time this feature is intensified by the prevailing dullness of trade, and the market for this material remains extremely flat. Prices are low, and entirely in buyers' favor.

Chicago Report.

Scrap.—Business is light and offerings from country Scrap collectors are large. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb.
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....
No. 2, such as Shovels, Hoes, &c	3.00	....
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5½¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5½¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—Business is quiet. Carload lots of 12 net tons or over are quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.00	$5.25
Milwaukee, Wis	5.00	5.25
Kansas City, Mo	8.20	8.45
Council Bluffs, Iowa	8.20	8.45
Lincoln, Neb	8.35	8.60
Sioux City, Iowa	8.20	8.45
Aberdeen, S. Dak	8.25	8.50
Dubuque, Iowa	6.30	6.55
Madison, Wis	6.50	6.75
St. Paul, Minn	7.50	7.75
Burlington, Iowa	6.50	6.75
Des Moines, Iowa	7.95	8.20
Davenport, Iowa	6.30	6.55
St. Joseph, Mo	8.20	8.45
Leavenworth, Kan	8.20	8.45
Omaha, Neb	8.20	8.45

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.85

THE PERRY STOVE COMPANY, Albany, N. Y., are at the present time bringing into special prominence their line of Oil Stoves, more especially No. 24 Shoo Fly with two-hole removable extension top and shelf, the Argand and the Fire Fly. In a page announcement elsewhere illustrations of these goods are shown and some particulars given.

CONDITION OF THE

Hardware Trade.

REPORTS indicate that trade in the different parts of the country varies considerably in tone and volume. A general feature of it is its unevenness, the orders of one day or week being relatively large and encouraging, and those of the next more or less disappointing. From several sections there is evidence of a steady improvement in the condition of things, and the indications point toward a gradual movement in this direction. The small trade are buying somewhat more freely notwithstanding the complaints that are made in regard to this matter from some markets, as more fully referred to in some of the following reports. It is also a significant fact that some of the representatives of large Western houses have recently been placing orders for future delivery, and express the confidence that before very long there must be a marked increase in the volume of trade. In the matter of prices there is little to add to what was said last week, the market being devoid of strength in many lines, with a tendency toward lower quotations. Collections give little ground for complaint.

Advices from Chicago.— A little better demand is reported for Shelf Hardware and also for roofing and tinners' materials from the general country trade. House furnishing goods and tinware experienced a little increase last week, but the gain then felt has been lost by this time and trade has relapsed iuto its former dullness. Copper goods have advanced slightly in consequence of the increased price placed on sheet copper. The improvement in this line of business is, however, more than counterbalanced by the lower rates made on staple goods. The prices named by jobbers ou the latter have been modified considerably during the past week, but greater concessions have been made to the city than to the country trade. Jobbers appear to be competing most vigorously for city business, although it is only a small proportion of the trade which they handle. Heavy Hardware jobbers have felt no improvement in their demand, but report their customers buying very sparingly and keeping stocks down as low as possible. Wagon builders are doiug considerably less than last mouth and appear to be afraid to make up stock to any extent. Collections are fair.

Notes on Prices.

Wire Nails.—There appears to bc something of a falling off in the volume of business, but the manufacturers are in receipt of many orders and are fully occupied. Some of these orders are from the large houses, but many of them are for comparatively small lots, the aggregate of the busineas, however, being large. Quotations are the same as last week, 95 cents at mill being a representative price, which is shaded only in the case of especially large and important orders. Small lots from store in New York are held at $1.20 to $1.25.

Advices from Chicago.—The advantages promised in February from the closer alliance made by Wire Nail manufacturers have all been lost, and the business in this branch has relapsed to its old condition. A prominent manufacturer says that, himself included, the manufacturers of Wire Nails are the biggest fools in the Iron and Steel trades. They have permitted themselves to fritter away one of the best opportunities they ever had to conduct a steady spring trade at a reasonably fair margin. The current demand is light, and yet the factories seem to be in possession of sufficient orders to enable them to run for the whole of this month and perhaps into the next. Their stocks are under the average held at this time of the year, and whenever specifications are sent in they are followed up promptly by telegrams if immediate shipments are not made. The trade, therefore, ought to be in good condition and prices ought to be maintained. Factory quotations are still about $1.05, Chicago, but with concessions on good sized quantities, while small lots from stock are selling at $1.15 to the country trade.

Cut Nails.—It is evident that the Eastern manufacturers are feeling more than for a long time the effect of Western competition, and within the past week or two some Western mills which have heretofore held aloof have been making quotations in Eastern markets. The price of Nails delivered in New York is 95 cents to $1 base. Small lots from store in New York are regularly quoted at $1.10 to $1.15.

Advices from Chicago.—The Steel Cut Nail manufacturers report a smaller volume of business, but they are still able to pick up enough orders to keep their works in operation. Prices are a little weaker, and may now be quoted at 95 cents on 55-cent average. Jobbers are selling small lots from stock at $1.10, but make concessions to the city trade.

Barb Wire.—There is a good demand for Barb Wire, but it is not so heavy as a few weeks ago. Manufacturers are, however, fully occupied with orders, and in some cases are not able to ship as rapidly as their customers would desire. Notwithstanding the volume of business the market is showing increasing signs of weakness, and concessions are made more freely than a few weeks ago. The market is represented by the following quotations on Four Point Galvanized delivered at the points named: Pittsburgh, $2.05 @ $2.15; Cleveland, $2.10 @ $2.20; Cincinnati or Allentown, $2.15 @ $2.25; Chicago or New York, $2.25 @ $2.35. There is more complaint in regard to irregularity in prices in Western markets than in the Eastern, but the effect of the concessions which are being made is quite generally felt.

Advices from Chicago.—The excellent demand for Plain Wire is perhaps having a better influence on the Barb Wire market than the actual demand for fencing from dealers and consumers. The miscellaneous consumers of Plain Wire are taking as large quantities as usual, so that there is less disposition to sacrifice the Barb Wire end, although business in this respect has fallen off to some extent. Prices on Galvanized Barb Wire may be quoted at $2.30 to $2.35 for small lots from stock, with 10 cents less for carload lots.

Cordage.—An increased demand is reported, being apparently stimulated somewhat by the low prices ruling. The market, however, is not in any better condition as regards quotations than at our last review, inasmuch as prices, in sympathy with the decline in raw material and as a result of active competition, continue low. The market is represented by the quotation of 6 cents base on Manila, a price which a few manufacturers decline to meet, but which on the other hand has by others been slightly shaded on large and attractive orders. Sisal and New Zealand hold quite steadily at 4 cents.

Sheet Zinc.—Matthiessen & Hegeler Zinc Company, La Salle, Ill., issue revised discounts on Sheet Zinc under date of April 11. The price continues $4.50 for Sheet Zinc in 600-pound casks, of the thicknesses between Nos. 9 to 15, inclusive, and of the widths between 32 to 46 inches, and of the lengths between 84 to 90 inches. The extras are also unchanged. The discounts as revised are as follows:

Discounts.	First class. 15 600-pound casks and upward.	Second class. 10 to 14 600-pound casks.	Third class. 5 to 9 600-pound casks.	Fourth class. Under 5 600-pound casks.
	Per cent.	Per cent.	Per cent.	Per cent.
Special	11	11	11	11
Cash with order	3	3	3	3
Quantity	3	2	1	0
Totals	17	16	15	14

All discounts are computed straight when money accompanies the order. Quantity discount is added to special discount in all cases. If remittance is received within 10 days of date of invoice the cash discount will be only 2 per cent. instead of 3 per cent., and not computed straight. Each order is strictly

subject to the quotation of the class to which it belongs.

Combined Cutlery Case and Money Drawer.—This article is put on the market by the Waddel Wooden Ware Works, Greenfield, Ohio, by whom it is sold at $12.50 each.

Glass.—There is a continuance of the better feeling in the Glass trade which has been noticed during the past two weeks, and an increased firmness in prices. Manufacturers and jobbers have to a great extent withdrawn quotations, and in many cases have advanced prices. It is claimed that the stock of Glass in manufacturers' and jobbers' hands is less than 500,000 boxes, while the customary stock on hand at this season of the year is stated as having been 2,000,000 to 2,500,000 boxes; while efforts are usually made to increase that amount to 4,000,000 boxes or over before the shut down. The limited stock of Glass on hand and the prospect of an increased demand are the causes of stiffer prices, as it is understood that the present stock would not be sufficient to supply the demands of the trade for one month under ordinary circumstances. In addition to this there is reported less than two-thirds of the number of pots in operation, or 1038 pots. There have been meetings held by the Glass manufacturers of Pittsburgh and of the gas belt, and while no official report of the proceedings have been published, it is understood that there is a desire for unity on the part of both. Pittsburgh quotations are given as 85 per cent. discount for single and 85 and 10 per cent. discount for double strength Glass. Under date of April 12, a Cleveland jobbing house quoted 85 and 5 for single and 85 and 10 per cent. discount for double strength Glass in quantities less than 25 boxes. There is a feeling of encouragement among Plate Glass manufacturers and jobbers, with a price agreed upon by the entire jobbing trade of New York, it is stated, of 70 and 10 and 70 and 5 per cent. discount, according to quantity. French Plate is quoted at 70 and 10 per cent. discount.

Old Metals.—There has been some improvement in the demand for Old Metals, but prices do not show much advance. The demand is generally fair for Scrap Iron at former rates, but the market is weak. The following quotations represent the ruling prices given by New York dealers:

Heavy Copper	℔ lb 7½¢
Light and Tinned Copper	℔ lb 6½¢
Heavy Brass	℔ lb 5½¢
Light Brass	℔ lb 4½¢
Lead	℔ lb 3¢
Tea Lead	℔ lb 2¢
Zinc	℔ lb 2¾¢
No. 1 Pewter	℔ lb 14¢
No. 2 Pewter	℔ lb 7¢
Wrought Scrap Iron, ℔ gross ton	$9.00 @ ....
Heavy Cast Scrap, ℔ gross ton	7.00 @ ....
Stove Plate Scrap, ℔ gross ton	4.50 @ ....
Burnt Iron, ℔ gross ton	3.50 @ ....

Old Rags, Paper, &c.—There is a moderately active market for these materials, but prices have not improved any. The following quotations are about the prices given by New York dealers:

No. 1 White Rags	℔ lb 3¼ @ 3½¢
No. 2 White Rags	℔ lb 2 @ 2¼¢
Mixed Rags	℔ lb ¾¢
Blues and 3ds	℔ lb 1 @ 1¼¢
Hard Sized White Shavings	℔ lb 2¼ @ 2½¢
No. 1 White Book Shavings	℔ lb 1¾ @ 2 ¢
No. 2 White Book Shavings	℔ lb 1 @ 1⅛¢
Light Book Shavings	℔ lb ¾¢
No. 1 Mixed Shavings	℔ lb ¾ @ 1 ¢
No. 2 Mixed Shavings	℔ lb ½ @ ¾¢
No. 1 Printed Books	℔ lb 1 @ 1¼¢
Ordinary Mixed Books	℔ lb ½ @ ¾¢
Newspapers	℔ lb 2-5 @ ½¢
No. 1 Manila Paper	℔ lb 1 @ 1½¢
No. 2 Manila Paper	℔ lb ⅝ @ ¾¢
Bogus Paper	℔ lb ½¢
Common Paper	℔ lb ⅜¢
Straw Chips	℔ lb ½¢
Binders' Clippings	℔ lb ½ @ ⅝¢
Jute Butts	℔ lb 1⅞ @ 2 ¢
No. 1 Jute Bagging	℔ lb 1 @ 1¼¢
Mixed Bagging	℔ lb ¾ @ 1 ¢
No. 2 Bagging	℔ lb ½ @ ¾¢
Hemp Twine	℔ lb 2 @ 2¼¢
Manila Rope	℔ lb 2¼ @ 2⅝¢
Jute Rope	℔ lb 1½ @ 1¾¢
Mixed Rope	℔ lb ¾ @ ⅞¢

Old Rubber.—The market for Old Rubber is fairly good. Prices rule about as follows, but are subject to variation and are somewhat irregular:

Car Springs, ton lots, ℔ lb.	@ $0.03½
Rubber Shoes, carloads, delivered at factory, ℔ lb.	@ .03½
Rubber shoes, less than carloads, ℔ lb.	@ .03¼
Large Hose, ℔ ton	@ 12.00
White Wringer Rolls, ℔ lb.	@ .03¾
White Syringes, ℔ lb	@ .03¾

Trade Notes.

Joseph Dixon Crucible Company, Jersey City, N. J., are putting the Cycle Chain Graphite on the market, which is the highest grade graphite reground with lubricating oil, and when applied to the chain of a bicycle, it is stated, penetrates the bearings and thoroughly lubricates and protects them from wear and rust. The same firm will soon put on the market the same material in the form of a solid stick, so that wheelmen can carry it in their tool bag.

The Rapid Safety Filter Company, 1343 Broadway, New York, are showing a variety of designs of their Filter, which filters the water passing through and cools it without letting it come in contact with the ice used for cooling. It will cool the water used, it is said, as fast as it will run from the faucet.

The advertisement of George H. Bell & Co., 114 and 116 Nassau street, New York City, directs attention to the Peerless Steam and Hot Water Heater. The announcement is made that this is the heater formerly known as the Schimpf Boiler, but the entire property and plant having recently been purchased by a syndicate, the name of the boiler has been changed to the Peerless.

A card in another column directs attention to the goods manufactured by the St. Louis Corrugating Company, 515 North Main street, St. Louis, Mo. This firm manufacture Sheet Metal Roofing, Siding and Ceiling of all descriptions from Sheet Iron or Steel, either black, painted or galvanized.

An advertising card issued by Fox & Fox, Isabella Building, Van Buren street, Chicago, Ill., calls attention to their business, which is that of glass brokers.

The Totten & Hoog Iron & Steel Foundry Company, Pittsburgh, Pa., manufacturers of Rolls and Rolling Mill Machinery, are operating their plant night and day. This firm are furnishing all the Mills, Shears, Engines and Boilers for the Emlyn Steel & Tin Plate Company of Summitville, Ind. They have just received an order from the Cumberland Steel & Tin Plate Company of Cumberland, Md., for three 24-inch Hot Mills complete, and an order from the Whitaker Iron Company, Wheeling, W. Va, for a large Double Shear and Engine; an order from the Morewood Company of Gas City, Ind., for a large Muck Shear, and an order from the Ohio Falls Iron Company of New Albany, Ind., for 22 Rolls.

E. E. Souther Iron Company, St. Louis, Mo., call attention in a card on another page to their Iron and Steel Roofing, and ask the trade to send for prices.

A meeting of the stockholders of the Joseph Dixon Crucible Company was held at their office in Jersey City, N. J, April 16, and out of 7345 shares 7215 votes were cast for the same board of management that has conducted the affairs of the company. The board elected consists of E. F. C. Young, John A. Walker, Daniel T. Hoag, Richard Butler, William Murray, Joseph T. Bedle and Jerome Gillett.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

The Detroit Heating & Lighting Company have received the contract and are putting in a plant for the lighting of the court house at Newark, Ohio.

The plans and specifications of the Oleson Block to be erected at Fort Dodge, Iowa, have been completed. It will be a three-story brick building, heated by steam, and will be furnished with all the modern conveniences.

The plumbing of the United States Post Office building in course of construction at Staunton, Va., has been let to Ed. Murray at a contract price of $2250.

Boyd & Schnaier, 347 Columbus avenue, New York, are doing the plumbing and gas fitting in the Montifiore Home, at Thirty-eighth and Hamilton streets, New York. They have just completed the contract for a new plumbing system, steam heating and marble work in the ten-story building at Broadway and Prince street.

G. Eaton will erect on Fulton street near Kedzie avenue, Oak Park, Chicago, a $6000 apartment house, to have exposed plumbing, steam heat and gas grate.

Hayward & Reynolds, 335 Columbus avenue, New York, are doing the plumbing work in the Empire Hotel, at Sixty-third street and Columbus avenue. The Durham system of house drainage will be used.

Wm. G. Morris, Frankfort, Ind., has the contract, amounting to $1000, for the plumbing work in connection with the Delphir water works extension. Sixteen hundred feet of 4-inch main will be laid.

In Cornelius Vanderbilt's Newport villa at Newport, R. I., which he calls "The Breakers," 25,000 feet of

the Newport indirect radiators are used and 10,000 feet of the same radiators are used in the chateau of Geo. W. Vanderbilt, at Biltmore, N. C. The radiators are made by the A. A. Griffing Iron Company, Jersey City, N. J.

The E. Keeler Company of Williamsport, Pa., have just completed the heating of the Y. M. C. A. and the Republican Club buildings in that city. In the former building a Boynton hot water boiler was used for service in connection with the swimming pool, and a Keeler 60 horse-power tubular boiler for the general heating. In the latter building a Boynton steam boiler for general heating and a hot water boiler of the same make, for bathroom purposes, were used. In both buildings the radiators were of the American Radiator Company's make. The company are at present engaged in the heating of the City Hall and Council Chambers, using one of their 60 horse-power tubular boilers and Corry radiators.

N. C. Harvey & Co., Duluth, Minn., are to install two Gurney hot water heaters in residences at Duluth.

The Walcott Hurlbut Company, 175-177 Lake street, Chicago, have received an order from Hamilton Bros., Marion, Ind., for a Syphon Eduction closet range, to be placed in a school building.

Cook & Chick, 253-255 Kinzie street, Chicago, have taken contracts for the steam heating in the apartment building of Charles Gloeckler, 583 La Salle avenue, and the store and flat building of M. Friend, 1047 Milwaukee avenue.

The J. L. Mott Iron Works 311-313 Wabash avenue, Chicago, are to place a No. 3 Star warm air furnace in the flat building of H. G. Byers, 76 Aberdeen street, and one of the same heaters in the residence of Nicholas Traft, South Evanston, Ill.

George C. Stevens, Columbus, Wis., is fitting up the residence of ex-Governor J. F. Lewis with a Gurney hot water heater and radiators.

The Board of Aldermen of Somerville, Mass., at its last meeting passed resolutions appropriating the sum of $14,000 for a four-room addition to the Knapp school house, to be borrowed on funded debt account, and authorizing the making of a contract with A. A. Sanborn for the heating and ventilating of the Geo. W. Durell school house.

The W. F. Porter Steam Heating Company, Minneapolis, Minn., have closed contracts with W. Ellithorpe, 3132 Stevens avenue, and Peter Jurgenson, Tenth avenue S. and Eighth street. The former will have hot water system and the latter steam. The Page boilers will be put in both residences.

The Lawrence Plumbing & Heating Company of Lawrence, Kan., have been awarded the contract for the plumbing and steam heating for the new county court house and jail at McPherson, Kan.

M. J. Corhoy, 78 Dearborn street, Chicago, has the plumbing in the flat building of Heissler & Junge, Thirty-fourth and State streets; residence of Joseph Slogel, Belmont avenue, and flat building of E. Stanton, 330 Ohio street.

Architects Faber & Pagels, Chicago, have designed a new Methodist church to be erected at the corner of Northwestern avenue and Cortland street. The building will be provided with a slate roof, kitchen and furnace heat.

Architect Cecil S. Corwin, Chicago, has designed for H. S. Mitchell a two-story attic and basement residence to be erected at Racine, Wis. The interior will be finished in hardwood and heated by hot water.

C. J. Hamhleton, Chicago, will construct a four-story store and apartment building at the northeast corner of North Clark street and Belmont avenue after plans by Architect G. L. Hallberg. Steam heat will be used.

Architect Frank L. Wright, Chicago, has designed for R. W. Roloson four two-story houses to be built on the east side of Calumet avenue, near Forty-second street. Hot water will be used for heating.

Architect A. F. Hussander, Chicago, has designed for T. F. O'Neil a large apartment house to be built at the intersection of Lincoln avenue and George street. It will be constructed of pressed brick and stone, with ornamental metal trimmings, and be heated by steam.

Architect W. J. Van Kuren, Chicago, has designed for J. E. Decker a three-atory apartment building to be erected on Park avenue, near Grove street, in Austin, Ill. It will be heated by steam.

Architect J. H. Huber, Chicago, has prepared plans for a residence to be erected on Newport avenue, near the lake. The building will be heated by hot water.

Among the contracts recently taken for steam heating by the Kelly & Jones Company, 48 to 52 North Clinton street, Chicago, are the following: O. Scheunemann's building, Belmont avenue and State court, and residence of Henry J. Luders, 217 South Leavitt street.

The D. S. Morgan Boiler Company, 22 West Lake street, Chicago, have contracts for steam heating in W. M. Grant's block on Michigan avenue, and in the residences of Mrs. E. M. Drew, Mrs. M. Hitt, H. B. Waterman and Tribelcock & Halligan, South Chicago.

The John Davis Company, 69 to 79 Michigan street, Chicago, have the contract for hot water heating in the flat building of Giles Hubbard, Forty-fourth street and Indiana avenue.

Coe & McMillen, Monticello, Ill., have been awarded the contract for steam heating in the new school building to be erected at Monticello.

Avery Stamping Company, Cleveland, Ohio, who are known as pioneers in heavy metal stamping, are putting on the market a full line of stamped steel hollow ware and are in a position to fill orders promptly. The line includes solid and riveted handle spiders, solid and riveted handle cake griddles, bailed cake griddles, round, flat and pit bottomed kettles, maslin kettles, stew pans, Scotch bowls, stew pots, hotel steel stew pans and pots, also pure nickel hotel sauce pans. The goods are furnished either polished, tinned, mirror polished or enameled, and are described as light, strong, durable, clean and of attractive appearance. The first cost of these goods is referred to as being far below copper and as rapidly replacing the same. The company also furnish the goods polished on the inside for what is called grease cooking. Attention is called to the nickel sauce pans, and while they are a little more expensive at first cost than copper, they are guaranteed by the manufacturers for 8 or 10 years. Emphasis is placed upon the finish and quality of the entire line of these goods.

It Is Reported—

Alabama.

That R. A. Posey has recently commenced the Hardware business at DADEVILLE.

California.

That J. W. Morrison has sold his Hardware store at SANTA ANNA to S. C. Wright of MCPHERSON, KAN., receiving in payment therefor a section of Kansas land and other considerations. Mr. Wright will conduct the business under his own name.

Colorado.

That Judge Walter T. Brown, for years engaged in the Hardware business at FORT MORGAN, but a resident of DENVER the past eight months, has purchased an interest in the Mitchell-Patton Mercantile Company.

Connecticut.

That on the afternoon of the 14th inst. fire broke out in the attic of the establishment of the Way Hardware Company, HARTFORD, and an hour later when the flames were extinguished the stock in the store below had been damaged by water to the extent of about $10,000. The company carry a stock of nearly $25,000, and a good portion of this was thoroughly drenched. Rubber blankets were placed over the stock as far as possible, but the water came down in such floods that scarcely anything could be kept dry. The loss is fully covered by insurance.

Delaware.

That the large Hardware stock of Bellah & Co., WILMINGTON, has been disposed of at auction.

Georgia.

That the Hutchinson Lumber & Supply Company of CORDELE are intending to engage in the Hardware and mill supply business, doing both a retail and wholesale trade. W. B. Hutchinson is president of the company, C. E. Arnt, treasurer; A. Kirtland, general manager, and J. W. Moore, secretary.

Illinois.

That T. E. Peck has opened a new Hardware store at VIRGINIA. He will also carry Tinware and Stoves.

That S. J. Stebbins' Hardware store, at 39 Van Buren street, CHICAGO, was damaged by fire on the 9th inst.

That German & Friedman of PRINCEVILLE have bought out the Hardware and Implement business formerly operated by Mr. Moore, at BRIMFIELD.

That T. B. Bray has sold his interest in the Hardware store at ELIZABETH to his partner, H. Weir. Mr. Bray will probably enter the dry goods business in the near future.

That Burder & Co. are proprietors of a new Hardware store at ORION.

That the residence and Hardware store of F. Webber, FAIRBURY, were destroyed by fire on the 8th inst.

Indiana.

That the Hardware store of William M. Johnson, at ILION, was entered by burglars on the 10th inst., the safe broken open and $300 stolen.

That fire on the 5th inst. destroyed the stable and warehouse of J. B. Barnes, Hardware merchant, of ANDERSON. The loss was $2000, with no insurance.

Iowa.

That arrangements have been perfected so that Gortner & Burt are again conducting their Hardware business at LAKE CITY.

That burglars broke into John F. Hays' Hardware store, at CLINTON, on the 6th inst., and stole goods to the amount of nearly $200.

That Mr. Stalford of DES MOINES has purchased G. F. Brayton's Hardware store at PERSIA.

That Wilber Van Cleef has bought the Hardware store formerly owned by W. J. Wood, ELLIOTT.

That Ford & Bailey is the style of a new Hardware store at DUNCOMBE.

Kansas.

That the Hardware store of F. B. Orr, HARPER, was burglarized a short time since. About $100 worth of goods were stolen.

That C. W. Young, dealer in Hardware and Implements, GREENLEAF, has sold his stock of Hardware to C. O. Graves. Mr. Young will continue the Implement business.

That C. S. Lucas of MARYVILLE, Mo., has decided to open a Hardware store at ARGENTINE about May 1.

Maine.

That Kelley & Eastman's Hardware store, at RANDOLPH, was entered by thieves on the 9th inst. and $150 worth of goods taken.

That John Watson, Hardware merchant, of HOULTON, is building a large storehouse 50 x 150 feet.

THE METAL WORKER.

Heating from Central Stations.

The heating of buildings distributed over wide districts from large central stations has been on trial in New York and other big cities for a sufficient time to give an answer with reference to the profitable or unprofitable character of the business. The financial results are generally believed not to have been satisfactory to investors in a number of these enterprises; yet, within certain reasonable limits, there is nothing apparent that would render a system of heating from a central station incapable of yielding a fair profit. The chief mistake appears to have been in the attempt to include too much in a single installment. It is not to be denied that however well steam pipes may be protected by insulating covering, any increase of their length from the steam generator to the place at which they deliver their steam increases the expense of supplying steam to that place. It is possible to conceive a steam pipe so long that all the steam which could enter it and flow through it under high pressure from a steam boiler would be condensed to water before reaching the extremity of the pipe. It is not probable that in any of the large plants referred to this limit has been reached; but there can be no doubt in some instances pipes have been laid underground to such distances as to condense a large percentage of the steam they conveyed before it reached its point of useful application.

Smaller Installments Suggested.

The question arises as to what great advantage can be gained by attempting so much from a single central station, even were it possible to reduce the loss through condensation to an amount comparable with the loss experienced with good practice in ordinary steam heating plants. A central station requires a certain amount of land to accommodate boilers and provide for a storage of coal. Suppose it to occupy one or two city lots. The amount of boiler power that could be accommodated thereon, with allowance for needful storage, would not be more than sufficient to supply to a few large blocks of city buildings the steam required for heating, elevators and other purposes. Now if it be required to supply a similar quantity of steam to buildings further away, is it not a common sense view that it is better to establish another central station at a distance from the first, rather than buy adjacent lots and build on one plat a plant large enough for both districts, thus increasing the cost of pipes for distribution, subjecting the enterprise to largely increased losses of heat, and also increasing the engineering difficulties in the construction and maintenance of the plant in working order? Many engineers asserted that this was the common sense view years ago, when the great heating schemes were first projected; and experience has proved the wisdom of this view.

Gas for Cooking.

The practicability of gas for cooking is demonstrated by its use to the exclusion of any other fuel in many apartment houses. In some of the handsomer houses in which a suit of seven or eight rooms rents for from $50 to $100 a month no other means for cooking are furnished. Compared with the kitchens of the past, these tiled and decorated culinary apartments, with modern cooking apparatus, are wonderfully attractive. The satisfaction attending the use of gas is illustrated by the experience of a furnisher who supplied 49 ranges in a new house, and though the tenants had never cooked with gas, but two out of them all insisted on having coal ranges; and on the arrival of summer these two were eager to secure gas ranges. The change was not a little influenced by the servants, who learned from those who used gas ranges how convenient and free from heat they were. A manufacturer of gas ranges who was desirous of comparing the cost of fuel for cooking employed the janitor in one of these large houses to make a canvass and learn the amount paid for gas. He found the average to be about $5 per month, including what was used for lighting, with the gas at $1.25 per 1000 feet.

The Armies of Unemployed.

The organization of unemployed men and tramps into so-called armies to march over the country is an entirely new idea. It will hereafter be referred to in history as originating after the panic of 1893. The movement seemed insignificant at first, and Coxey's march to Washington was regarded as a joke to enliven the columns of the newspapers for a few days and was then expected to pass into utter oblivion. But the events of the last few days have put a much more serious aspect on the situation, and there is promise of enough happening to make future historians inquire closely into the causes, progress and results of this curious manifestation of unrest. At the present time there are some eight or nine "armies" struggling to reach Washington from various parts of the country. In a numerical sense these "armies" form no special menace to the order and peace of the country. There are too few of them and they are too widely scattered to do much damage. They may cause annoyance to the towns through which they pass, but such towns are but a small part of the country as a whole. As long as the "commonwealers" or "industrials," or whatever they may be termed, are so few in number they can do no particular damage even if some of their leaders indulge in very foolish talk. Experience has shown, however, that when there are many workmen idle some join the professional loafers and hoodlums in starting riots in large cities which cause much destruction to property. The incentive is frequently quite light. The railroad riots of 1877 would not have been so serious and disastrous if the trouble had been confined to those immediately interested. But idle workingmen and the riffraff of cities, always eager for turbulence, took up the cause of the disgruntled railroaders, made common cause with them and carried the conflict far beyond the anticipation of the leaders of the original strikes.

It is asserted upon good authority that at present prices there is no profit attached to galvanizing steel sheets. Manufacturers are contented, perforce, with a fair profit on the black sheets and go to the trouble of galvanizing in order to find a market for the products of their mills. An effort is being made to get all galvanized iron manufacturers into the Galvanized Iron Manufacturers' Association, for the purpose of maintaining better prices, but there are a few who have not yet signified their intention and independet action continues.

Ex-President Harrison, in concluding his course of law lectures at the Stanford University of California, gave the students some advice which is significant as coming from so competent a source. He counseled them to "stick to their profession, avoid politics and never seek office."

Negotiations are, it is said, pending for uniting the independent cordage interests of the country with the United States Cordage Company.

THE LETTER BOX.

Protection for Copper Cornices.

From J. F. F., *Savannah, Ga.*—Will *The Metal Worker* inform me what is the paste used to put on copper to keep it from tarnishing while it is being worked into a cornice, and what should be used for cleaning after the cornice is made? There are various ways of cleaning copper, but when the hands are placed on it the place touched soon discolors. If the cornice is cleaned after it is made, while putting up it is again covered with finger marks. What I want is something to keep the copper clean while it is being made up.

Note.—We shall be glad to hear if any of our readers have been successful in overcoming this difficulty. The use of lacquer for coating the material and gloves have been suggested, but are not found to be generally used. The common method of cleaning copper work is to scour it with fine pumice or emery made into a paste with oil, so it will not blow away. The powder is removed by polishing with some soft material, and if it has made no scratches and the corrosion has not been too deep, a clean, bright surface is left. This can either be done before or after the work is in position on the building. With this material there is nothing to start discoloration anew, and the surface is left to take the color naturally resulting from exposure.

Lukewarm Water.

From J. R. F., *Southington, Conn.*—Referring to the letter of "C. D. F." in *The Metal Worker* of April 14, would say that I have had the same trouble which he reports and found it to be due to impeded circulation in the pipes. If he will take down the boiler he will find the bottom pipe full of sediment, especially if the boiler has been in use a number of years. It is possible, also, that he will find that the tube which connects with the cold water supply inside of the boiler has rusted off and dropped out of place, so that the cold water mingles with the hot.

Seeking Education.

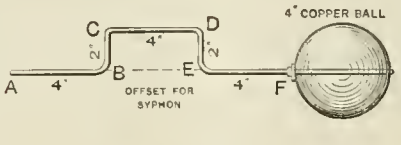
From SUBSCRIBER, *Washington, D. C.*—I notice your article in *The Metal Worker* of April 7 on the subject of self education. Please give names of books you would recommend and the most important studies, or with whom can I correspond for information.

Answer.—We would be glad to assist our correspondent in mentioning books for reading or study, but he has not told us what line he wishes to pursue. Of course he knows that the groundwork of all education is the usual school studies of arithemetic, geography, natural philosopy, history, &c. But we should imagine that he was looking for instruction in some particular trade, and it would be quite useless for us to give him a list of works on electricity, for instance, if he were seeking self education in plumbing. If our correspondent wishes to take a regular course of this sort we would advise him to write to the Correspondence School of Mechanics and Industrial Sciences, Scranton, Pa., who give instruction by mail in a great number of different branches.

Straight and Crooked Levers.

From APPRENTICE, *London, Ont.*—I am a reader of *The Metal Worker* and an apprentice at the plumbing trade, and will be obliged to you for an answer to the following: Does the offset on a ball cock lever add to its power in action? In the accompanying sketch the length of the lever is 16 inches. Would not a lever from A to F 12 inches long be just as powerful?

Answer.—Our correspondent's view of the matter is correct. A ball



Straight and Crooked Levers.

cock arm is simply an ordinary lever with the fulcrum at A and the power applied at F, which is the point at which the buoyancy of the copper ball acts on the lever to force it up. The power of a lever of this sort depends on the distance between the application of the force and the fulcrum, and it practically makes no difference what the shape of the lever is. The offset, therefore, does not increase or diminish its efficiency. We, of course, assume that the lever arm is rigid.

Boiler Rumbles.

From E. W. Y., *Pawling, N. Y.*—I would like to have explained through the columns of *The Metal Worker* what causes and how to remedy the rumbling noise in a range boiler when hot water is drawn out. Should the cold water pipe from the boiler to the range be lower at the range?

Answer.—In *The Metal Worker* of January 27, February 3 and March 17, an explanation is given of the cause of the rumbling noise. It is due to the generation of steam in the water back and its passage to the boiler, where it condenses, and the water rushing in to fill the space that was occupied by the steam makes the noise. A remedy used in a number of cases is a pipe called a relief pipe, running from the top of the boiler to the top of the tank, where it turns over so that the steam generated may pass off as fast as it is made and the noise be avoided. Owing to surrounding conditions it is not always possible to so set a boiler that the pipe running from the boiler to the range will be lower at the range, but where it can be done it is undoubtedly the better plan.

Wants an Insulator.

From E. T., *Wyncote, Pa.*—Can you tell me a good way to pack or wrap pipes to prevent them from freezing, where they must be run up on the outside of a building?

Answer.—The most satisfactory way to protect pipes from freezing is to box them in and fill the space around them with some non-conductor of heat. The large tanks on the top of high buildings in New York City which supply the buildings with water have a pipe that leads from the tank down through the roof, and the length of exposed pipe varies from a few inches to some feet. A very common practice is to box these pipes and fill the space with sawdust. Sometimes mineral wool or asbestos is used, and at other times the pipes are securely wrapped with several thicknesses of hair felt.

Chimney Condensation.

From R. C., *Fillmore, N. Y.*—Will *The Metal Worker* please inform me what makes the black liquid run from a furnace smoke pipe where the pipe is long and runs up through the house, and if there is any way to stop it? We have pipes that give considerable drip from condensed smoke, especially when wood is burned.

Note.—The black liquid mentioned is due to condensation in the chimney or smoke pipe, caused by the contact of the smoke and vapors with bodies that are colder than they. In a great number of cases this is due to a lack of draft and also to the size of the chimney. It has been asserted by some practical men who have had experience in this line that a chimney less than 8 x 12 will not give satisfaction where wood is used as a fuel. To prevent the drip coming to the outside of the pipe a common method of putting up the pipe is to reverse the connections, so that the smaller end of the pipe fits inside the stove collar and the other end receives the smaller end of the next joint of pipe, and so on to the chimney. This permits the condensation to run back toward the stove, without escaping at the joints.

Roofing Material Wanted.

From J. D. G., *Bozeman, Mont.*—In *The Metal Worker* of April 7, "M. H. R," Winnipeg, asks for suggestions on metal roofing. Without attempting to solve the problem, I would say that the climate he describes is the same as ours, and the roof that gives the best satisfaction here is the standing seam tin roof. The better the tin the better the results. Our roofs, however, do not give us half the trouble that the gutters do, and I would like to know the very best material for gutters, regardless of cost. How would aluminum do? Can it be joined or soldered? I would like to hear from "M. H. R." or any one else in regard to this proposition.

Note.—The soldering of aluminum is the difficulty met with in making use of that metal. There are roof compositions manufactured, however, into which aluminum enters, which we believe are easily soldered and worked like other metals. The quality in a roof material to be sought for in climates where there are great extremes of temperature is small expansion. Zinc, for instance, would be very difficult to handle in such a climate. We believe, however, that any metal can be laid with satisfactory results if an ingenious roofer will allow properly for the expansion and contraction of the sheets. For instance, the method of laying zinc in ordinary climates, if applied to tin plate in the climate of Winnipeg, would probably give good results. We will be glad to have our readers discuss this whole question.

From THE METALLIC ROOFING COMPANY OF CANADA, LIMITED, *Toronto, Ont.*—In your issue of April 7 we notice a letter from "M. H. R.," Winnipeg, Manitoba, respecting roofing material suitable for that climate, which varies from 50° below zero to 100° in the shade. We manufacture materials especially suitable for the Manitoba trade and have sold large quantities without receiving any complaints. It is a roof of sheet metal, and full information may be obtained from J. H. Ashdown, wholesale hardware merchant, Winnipeg, who is our agent.

Wants to Build a Fruit Dryer.

From C. O. F. Y., *Glendale, Ariz.*—I would like some information with reference to the construction of fruit dryers, using both hot air and steam, from the readers of *The Metal Worker* who may be engaged or have had experience in the construction of such apparatus.

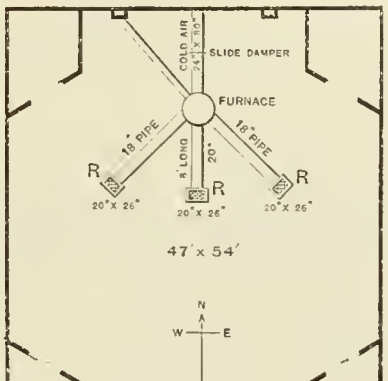
Sheathing for Tin Roofing.

From F. & H., *Brookville, Ind.*—In reply to the query from "B. J. P." in *The Metal Worker* of April 14, as to sheathing under tin roof, would say that tight sheathing would prevent tin from rusting on the lower side, but it would be more expensive than if the sheathing is laid a few inches apart, and it would be more difficult to work on a steep roof than if there was a space between the sheathing boards for a foothold. We use rosin sized or water proof paper under all our work and find that it prevents rust, is cooler in summer and warmer in winter, deadens sound and prevents drip of melting frost.

From C. F., *Erie, Pa.*—In reply to "B. J. P." of New York, in *The Metal Worker* of April 14, would say that by all means close sheathing is the best, at least when no felt is used. To illustrate the fact, only lately we had occasion to take off a tin roof for a new addition that had been on about five years on sheeting that was quite loose and having a good many knot holes, and as there was no felt on, we found that where the tin had been protected by the sheeting it was as bright as the day it was put on, while over the cracks and knot holes it was very rusty. I think there is the proof of the pudding. The only thing I would advise with close sheeting is to provide the attic with ventilation.

Wants Furnace Suggestions.

From A. L. F., *Roanoke, Va.*—In *The Metal Worker*, March 24, I notice that a Montana tinner asks for information in regard to setting his furnace. I submit a sketch and such information as I think would help him out in his dilemma. If I had the job of putting up this furnace I should locate it as shown by my diagram, taking it for granted that the south of the building was the entrance and north was the rear, and not built up against any other building in the rear. In the first place, three registers will equalize the distribution of the warm air in the room. The north and west side of the room will always be colder than the east and south. I would place the cold air flue on the north or northwest side of the building, which all furnacemen understand is the proper location. A damper should be placed in the cold air flue, as at times when the wind blows at a rapid rate it is necessary that some of the supply should be cut off, as a larger amount of air will be forced through the furnace than can be heated. By placing the furnace nearer the flue it will help the draft, and from the fact that the furnace is in the north of the building the hot air pipes can be extended some little distance without a material loss in heat. I would suggest that a round pipe be extended up the chimney, say, 10 or 15 feet, as large as the flue will admit (the entire length of the flue would be better), placing an elbow as large at one end as possible to receive the furnace pipe. Then plaster around the elbow, so as not to allow any air to enter the chimney flue without passing through the furnace. I should not advise using two flues. There might possibly be some trouble if one of the flues had a stronger draft than the other. Under some circumstances the one with the poorest draft would be a disadvantage.



Wants Furnace Suggestions.

I presume that soft coal is used from the size of the smoke pipe and the collar on the furnace. We are always ready to lay the blame on the chimney flue when the furnace smokes or there is a sluggish fire, though it is not always the cause of the trouble. If the furnaceman is a pretty good mechanic let him examine the check plates that are placed in the majority of furnaces and see if they cause the trouble. Some of the best makes of furnaces will not give satisfaction when using soft coal, owing to the draft of the chimney not being strong enough and the check in the furnace being too great. I have remedied three furnaces this winter that smoked so badly that the owners threatened to take them out, owing to the check being too great when using soft coal, causing them to smoke to such an extent as to be almost a nuisance. There is no danger in removing a portion of the check plate that the draft will be too great, as soft coal produces such an enormous amount of smoke and gas when it is first thrown in the furnace that it is almost compelled to force its way out through the door or some other part of the furnace that is not perfectly air tight, unless there is ample outlet for it to escape to the flue. In the matter of the cold air flue, as shown on his diagram, it seems to me to be a very bad idea to take the cold air from the main auditorium. While some furnacemen suggest this plan, the fact that the air is being reheated and sent back into the room to be inhaled, possibly a dozen times during services, does not commend itself to me as being the proper way to get fresh air, which is so essential where there is a large number of people. Although those who approve this plan contend that the air is purified by passing through the furnace, I have other ideas.

Material for Roof Gutters.

From L. H., *Masontown, Pa.*—I would like to know which is the more lasting for roof gutters—copper of ordinary thickness or the best grade of roofing tin.

Answer.—Roofing tin, as our correspondent knows, is sheet iron, or rather steel coated with a mixture largely composed of lead. The finished plate, therefore, is equivalent to a sheet of iron and two thin sheets of lead alloy. Copper is a single homogeneous metal. Assuming that the copper that our correspondent has in mind is of the same thickness as the finished plate of roofing tin, it is evident that copper will prove the more lasting material. The length of life of the roofing plate, of course, depends upon the endurance of the lead coating. When this is worn away, abraded, or injured in any way, the iron or steel quickly rusts through. We do not know the relative endurance of lead and copper. Suffice it to say that roofs covered with lead sheets or copper sheets will last indefinitely. It

is of little consequence in modern building construction whether a roof gutter lasts 150 or only 100 years. In either case it will be apt to outlast the house itself, so it is needless to define the exact limit of endurance. We have no doubt that if our correspondent uses the best terne plates for his roof gutters he will find they will prove very durable.

Ohio Sheet Iron Trade.

In sheet mills in Central Ohio and adjacent districts there is a much better feeling prevailing. Jobbers of the West, Northwest, and South are sending their inquiries broadcast asking for prices for summer and fall delivery, and they appear to have realized that bottom has been reached. If this is not a fact and prices do go lower they will hug the cost marks so closely that there will be no margins for contingencies, and a few breakages or stoppages will wipe out the small profits, obtainable only under the most favorable conditions. Considering the fact that jobbers are in the market and that the roofers are doing better business, there ought not to be any further decline in sheet iron prices. The fact that the fine weather of the past two weeks has stimulated building operations is given as a cause for improvement in the iron and steel roofing trade. At Canton, Wheeling, Cambridge and Cleveland it is reported that inquiries are more numerous, and more sales are resulting than at any time for six months past. The demand for conductor pipe, eaves trough, and other building material made from galvanized iron is particularly good, and rolling mills appreciate this fact. The bulk of the trade in roofing and corrugated sheets is in light gauges for small consumers. Orders for heavy gauges are few and far apart. This is accounted for by decreased construction of buildings for manufacturing purposes. An order for about 30 tons of Nos. 18 and 22 corrugated for covering the buildings of the Canton Rolling Mill Company, Canton, Ohio, was placed with the Canton Steel Roofing Company; the black sheets will be made at New Philadelphia. The buildings referred to will contain sheet mills, and it is estimated that the entire product will be consumed by home concerns.

According to the lately published census returns, the total valuation of property in the United States in 1890 was $65,037,091,197, which was an increase of 49.02 per cent. over the returns of 1880, representing a per capita sum of $1039. That the growth of the wealth of the country during the past five decennial periods has proceeded at a much higher ratio than the increase in population is shown by the following figures: In 1850 the total valuation of property in the country was a little over $7,000,000,000, or $308 per capita. In 1860 it was $16,000,000,000, or $514 per capita. In 1870 it was $30,000,000,000, or $780 per capita, and in 1880 it was $43,500,000,000, or $870 per capita. New York stands as by far the richest State, its wealth being estimated at $8,500,000,000. Pennsylvania comes second, with $6,000,000,000, and Illinois third, with $5,000,000,000.

Ground was broken on April 18 for the work of sewering the city of New Orleans.

Borough Polytechnic Institute, London.

In the early part of last year we presented an account of the then recently started trade training classes held in connection with the Borough Polytechnic Institute of London, England. This institute was the first established under an act of Parliament passed in 1891 to encourage technical education in Great Britain. It was opened in September, 1892, by the Earl of Rosebery, the present Prime Minister of England, with well equipped classrooms, halls, laboratories and offices for the efficient conduct of the general technical education and recreative advantages which it was designed to provide for the working men and women of the South London district, in which it is located. Its courses of instruction cover a very wide field, embracing the teaching of subjects to suit all trades and classes, thus aiming to promote greater industrial skill and general knowledge among the younger working people of the British metropolis.

Trade Classes.

Among the principal educational departments of the Borough Polytechnic Institute are the classes for practical and theoretical instruction in various trades. These trades include plumbing, sheet metal working, carpentry, engineering, blacksmithing, pattern making, bricklaying, bookbinding, &c. Instruction is only given to those already engaged in these trades, and is arranged to supplement the training of the factory or workshop and not to supersede it. For this reason no student is admitted for trade training only, but is expected to join at least one of the science or art classes, such as the elementary science class or the classes in practical geometry or technical drawing, which are open on nights other than those devoted to trade instruction. Thus it is intended to give the mechanic an all round training which will help him in his trade, by stimulating his mental faculties as well as his manual capacity.

The New Workshops.

The trade classes were at first housed, as a temporary measure, in the original institute building, until adequate accommodation and facilities could be provided. They soon outgrew the space there at their disposal, and it was decided to at once erect new workshops for the trades in a separate building. This was done, and the shops were completed and opened for use in March of this year. The plan view, presented herewith, gives a good conception of the arrangement of the different shops. All, with the exception of the bricklayers' and bookbinders', are top lit with lantern lights, the side sashes being hinged to open for ventilation. They cost $15,360 to build and nearly $6000 to equip. The students of the trade classes assisted in the work of furnishing and fitting them; sheet metal workers, carpenters, bricklayers, &c., contributing their labor and skill with good effect.

Progress of Trade Training.

The new and more capacious accommodation thus provided enables the managers of the institute to largely develop and extend the work of the trade classes, which have been found to meet a very pressing need in South London. Eighteen months of work have shown that the advantages offered are eagerly grasped by the class for which they were intended. The entries in the trade and technical classes for the first session were 497. In the last session—October, 1893, to May, 1894—they numbered 701, an increase of 264, and the prospects are that the next courses will be still more numerously attended.

Plumbing Instruction.

Instruction in plumbing is given on three nights of the week: Tuesdays, Thursdays and Fridays. The full curriculum extends over three years. The first year's course is a preliminary and general one, consisting of instruction in practical geometry, technical drawing, freehand and model drawing, and elementary mechanics, including mensuration This course is planned to serve as a preliminary for those about to enter or who are already engaged in any of the trades. Students, however, who have a knowledge of any two of the above named subjects are allowed either to take up other subjects or else to pass at once to the second year's course of the trade in which they are employed. In the plumbing trade, the further courses are arranged as follows:

SECOND YEAR'S COURSE.

Mondays, 8 to 10 p.m., plumbers' work (technical).
Thursdays, 7.30 to 10 p.m., special preliminary science course (lectures and laboratory work).
Fridays, 8 to 10 p.m., plumbers' work (practical).

THIRD YEAR'S COURSE.

Tuesdays, 8 to 10 p.m., plumbers' work (advanced technical).
Thursdays, 8 to 10 p.m., plumbers' work (advanced practical).
Fridays, 8 to 10 p.m., building construction and special lectures.

These courses, consisting of lectures and workshop practice, comprise instruction in lead bossing, pipe bending, soldering and wiping joints, &c.; lectures on sanitary arrangements in dwelling houses and other buildings, water closets and their fittings, baths, traps, lavatories and sinks; soil pipes, their ventilation and arrangement; water supply, house cisterns, roofing, &c.

In addition, a special class for journeymen and foremen plumbers and others engaged in the building trades is held on Monday evenings from 7.30 to 9 o'clock, when instruction is given in "builders' quantities," including measuring work, taking off quantities from drawings, squaring dimensions, and bringing the same into bill ready for pricing out to form a builder's estimate.

Sheet Metal Work.

The preliminary or first year's course for sheet metal workers in tin plate, zinc, iron and copper, lamp makers, boiler makers and coppersmiths is similar to that detailed for plumbers. The second and third year's courses are laid out respectively as follows:

SECOND YEAR'S COURSE.

Mondays, 8 to 10 p.m., metal plate work (technical).
Thursdays, 7.30 to 10 p.m., special science course.
Fridays, 8 to 10 p.m., metal plate work (practical).

THIRD YEAR'S COURSE.

Mondays, 7.30 to 10 p.m., machine construction and drawing (for iron workers and boiler makers).
Tuesdays, 8 to 10 p.m., metal plate work (technical).
Thursdays, 8 to 10 p.m., building construction and drawing (for zinc workers).
Fridays, 8 to 10 p.m., metal plate work (practical).

The instruction includes geometry and its applications to pattern cutting;

patterns for elbows, T pieces, round, oval, oblong and other articles of equal and unequal slant; tea bottle top, bath and hood patterns by long and short radius methods; cowls, ships' ventilators and patterns for boiler makers; seams riveted, grooved and soldered; solders and soldering, composition of useful alloys, tinning and galvanizing processes; the properties of iron, steel, tin, lead, copper and zinc; theory and practice of hollowing, raising and planishing metals.

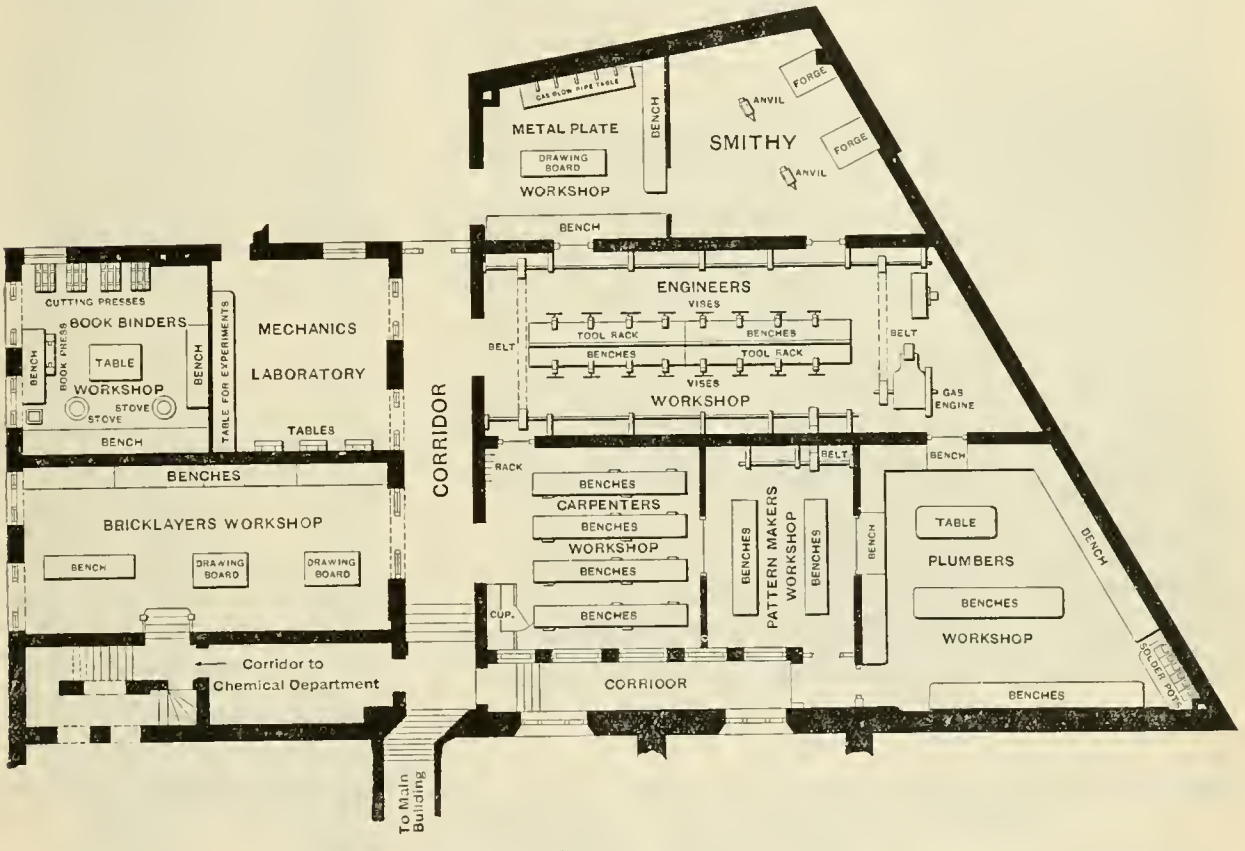
The new laboratory and workshop for metal workers is fitted up with all the necessary appliances for practically carrying out the above courses. During the session lectures on metals and other cognate topics are given by C. T. Millis, M. I. Mech. E., principal of the education department. It is to Mr. Millis we are indebted for the information here given.

Fees for Instruction.

As the benefits of the institute are intended to reach apprentices and workers in receipt of a small weekly wage, the class fees are fixed at an exceedingly low rate, ranging from $1 to $2 50 for each yearly course, so that the best instruction is placed within easy reach of all who are desirous of availing themselves of it. Moreover, students under 19 years of age are admitted at half these fees, and members of the trade classes may enter classes in other subjects at half fees.

Certificates and prizes are awarded by the institute to the students who are found proficient; examinations being held at the end of each session by representatives of the Science and Art Department of the city and guilds of London Institute and the Society of Arts.

The institute is under the direction of an able and experienced body of technical educators, and the trade classes are taught by master workmen of the respective crafts. The work already done by the students is said to be of a most creditable character. Specimens executed by the classes were on exhibition on the night of the recent opening, and were very favorably mentioned by the various London trade journals.



Borough Polytechnic Institute, London.—New Workshops.

New Publications.

ELEMENTARY METAL WORK. A Practical Manual for Amateurs and for Use in Schools. By Charles Godfrey Leland, late Director of Industrial Art Work in the Public Schools of Philadelphia. Macmillan & Co., New York, 1894. $1.50.

In this volume Mr. Leland has put into the hands of students of art metal work a manual which appears to be a very complete and helpful guide to the mastery of this fascinating craft, beginning with its first principles and carrying the instruction through to the highest stages. Although designed, as its subtitle indicates, mainly for use in schools and for the benefit of the amateur metal worker, the book goes very thoroughly into the art of decorative working in sheet metals, and contains much matter which would render it useful to practical metal workers. The book is devoted to an exposition of the processes of cold metal work, beginning at the rudiments and working steadily along into the most advanced forms of artistic and decorative work. It is divided into six portions, treating respectively of bent iron or strip work, flat sheet metal work, molded sheet metal work, *repoussé* or embossed metal work, ornamental silver work, and nail, scale and stencil work. The illustrations, 124 in number, are of excellent quality, and include engravings of all the tools and appliances used in the manipulation of cold metals, samples of elementary forms and curvatures, and a wealth of artistic patterns, with examples of the best ancient and modern metal work. Directions are given for making rings and curves of strip metal into objects; for soldering, shearing, chiseling, fret sawing and pressing sheet metal; for embossing sheet metal on wood and on pitch, and for every phase of cold metal working. The book contains 110 pages, is handsomely gotten up on thick paper, and bound in an artistic cover of black and bronze, making it a very attractive volume.

S. J. Seneca, Havre de Grace, Md., who in 1873 adopted as a trade-mark for his canned goods the words "Red Cross Brand," and the emblem of a red cross, which latter was registered as a trade-mark at the Patent Office in 1876, is naturally much disturbed over the bill prohibiting the use of the red cross as a trade-mark or designation. Mr. Seneca thinks that as the American Association of the Red Cross Society was not formed until 1881, his prior right in this matter should receive consideration from Congress. A trade-mark is at times a very valuable piece of property, and the interference by Congress with established rights in a matter like this would, we think, only be justified by a proper compensation.

The annual prize given by the French Society for the Encouragement of National Industry for the Utilization of Waste Products has been awarded this year to a Mons. Martinon for his process of recovering the tin from water in which silks have been treated with bichloride of tin for the purpose of imparting weight. By adding milk of lime to the water and by properly agitating it the tin settles down in a few hours, in the shape of oxide, and can be readily collected and utilized.

STEAM AND HOT WATER.

Estimating Surface Required.

From T. A. A., *Pennsylvania.*—Will *The Metal Worker* please answer the following questions on steam heating? Is it a good rule to multiply the length of a building by its breadth and the results by its hight, then strike off the two right hand figures and count the remainder as the number of square feet of surface required to heat it? Please publish a good rule for estimating the amount of radiating surface to be used for the space to be heated. What difference should be made in estimating for low pressure steam and for hot water in house heating? How many feet of 1-inch and 1¼ inch pipe should be used for 100 cubic feet of space?

Note.—It is probable that the secret of success in house heating is in correctly estimating the surface and properly piping it. No one rule is applicable to all kinds of buildings, whatever its basis may be, and of those in use none needs so much judgment in their application as the cubic foot rules. The rule given allows 1 square foot of surface for each 100 cubic feet of space, and for stores, halls and churches this might give satisfaction. For use in house heating it would in most cases prove unsatisfactory, as a wide variation is found necessary. Sometimes 1 square foot of surface is used for 70 cubic feet of space when the rooms are small and so located that but little heat is required; and often 1 square foot of surface is used for as little as 30 cubic feet of space when the rooms have a large glass surface and are much exposed. About 3 lineal feet of 1-inch pipe and 2⅜ feet of 1¼-inch pipe expose 1 square foot of surface, and in a room 15 x 15 x 10 feet, allowing 1 foot of surface to each 50 cubic feet of space, 45 square feet of surface would be necessary, requiring 135 lineal feet of 1-inch pipe, or 105 lineal feet of 1¼ inch pipe. This is equivalent to 6 feet of 1-inch pipe or 4⅜ feet of 1¼-inch pipe to 100 cubic feet of space. As our correspondent wishes to learn how to estimate surface, we would refer him to "The Metal Worker House Heating Essays," which give a number of different rules that have been used by different authorities for both steam and hot water.

Mixing Valves.

BY HELIOS.

Fig. 1 shows the manner of connecting a mixing valve for indirect radiation. In Fig. 2. On the outside of the hot air pipe place a crank and secure to the damper rod with a set screw, and from the end of this crank run a chain over pulleys up to the room with which the indirect radiation is connected. The chain can have a ring on the end and brass hooks to hold the chain.

A mixing valve connected to indirect radiation is used to regulate the temperature of the air entering the room from the indirect radiators. In Fig. 1 the mixing valve is closed, and all the air passing into the room that this radiator is connected to has to pass over the radiators in the box. If the room is too warm, by drawing up on the chain it will allow the cold air to enter the hot air pipe, which will lower the temperature of the air entering the room. If only cold air is wanted, draw the chain all the way up, and the damper will close the opening from the indirect radiators to the hot air pipe and open the cold air pipe wide open.

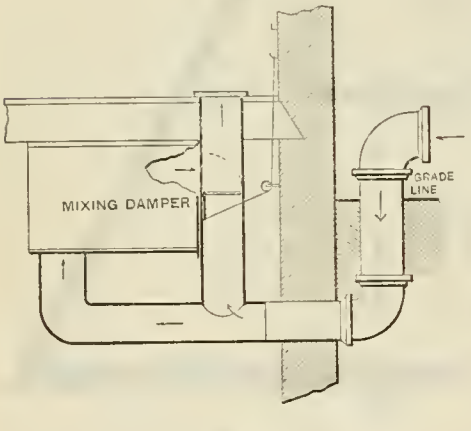


Fig. 1.—Mixing Valve Connected for Indirect Radiation.

Fig. 2.—Galvanized Iron Damper.

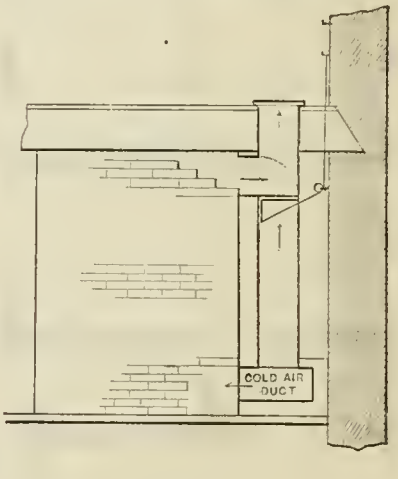

Fig. 3.—Brick Chamber for Indirect Radiation.

MIXING VALVES.

Fig. 3 shows indirect radiation built in with brick work, with cold air duct and mixing valve outside the brick walls. The brick work from the floor to the under side of the radiators should be 8 inch walls and above the supporting bars 4-inch walls. Cast iron doors and frames should be built into the brick work above and below the radiators. The mixing valve is connected the same as in Fig. 1.

In making the mixing valve connection take a branch the full size of the cold air pipe from the top of the cold air pipe as it enters the cellar. Start with a round pipe and form into a square pipe at the mixing valve. The opening from the indirect radiator must be full size of hot air pipe. Make a damper of galvanized iron and have it lap over on all sides of the opening from the indirect radiator ½ inch. Take a piece of round iron flat in the middle and bolt to one side of the damper as shown in Fig. 1. In Fig. 1 the arrangement and connections to the indirect radiators are the same as shown in a previous article. The cold air supply, as shown in Fig. 1, is taken from above the grade and carried down and through the wall of the building. An elbow is placed on the end to keep the rain from falling into the pipe. An iron ring made from ¼ x 1-inch iron is covered with wire screen and cemented into the elbow. The elbow on top and the pipe down and through the wall are vitrified sewer pipe. The pipe connecting to the indirect radiators is made of galvanized iron.

Heating Coils in Furnaces.

From C. O. F. Y., *Glendale, Ariz.*—I have just read the article on heating coils in furnaces in *The Metal Worker* of April 7, by an unknown correspondent, which sets forth some excellent ideas. It is the successful accomplishment of such work as described that makes the distinction between the expert and the novice, and the man who relates his experience as minutely as has been done in this case for the guidance of the craft receives their appreciation, although he very seldom hears of it.

Scollay Hot Water Thermometer.

The illustrations herewith show a new hot water thermometer being brought out by John A. Scollay, 74-76 Myrtle avenue, Brooklyn, N. Y. It consists of a nickel plated case with a dial and the expanding liquid, as shown in Fig. 1. A thermometer is shown in Fig. 2 which may be conveniently carried in the pocket, or is less conspicuous in use as is sometimes desirable.

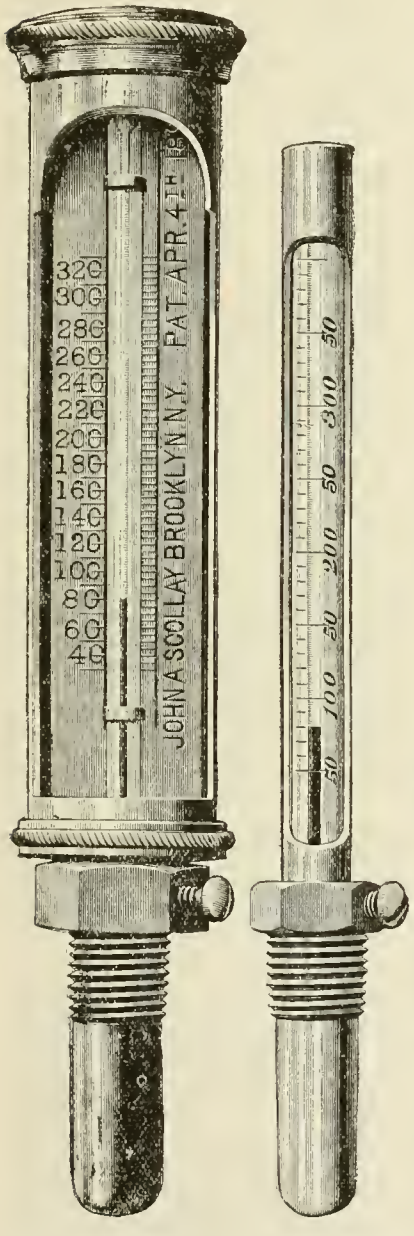

Fig. 1.—Thermometer for General Use.

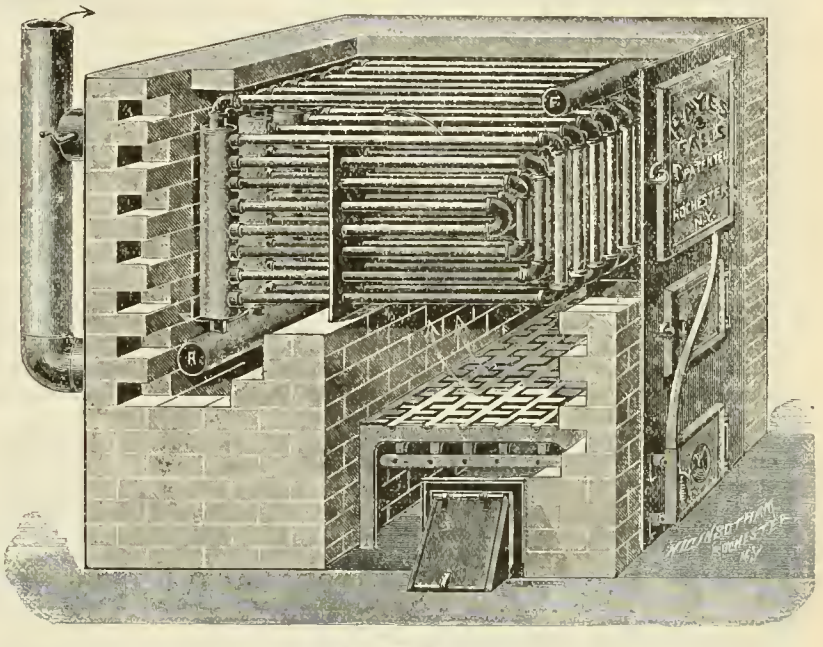
Fig. 2—Pocket Thermometer.

Scollay Hot Water Thermometer.

The features of the thermometer are size of threaded part, which is made to fit a ½-inch opening, and the fluid. A set screw at the side releases or fixes the thermometer in the threaded part, enabling that part to be readily set in the system. This part has a thin shell exposed to the water and is filled with mercury. The glass tube holding the expanding fluid is protected by a brass cylinder with a space around it. This portion extends down into the mercury. The fluid used is black and is adapted to registering temperatures as high as 500°. The black color, it is said, is permanent, so its hight on the white dial can be readily seen from the strong contrast.

The Torrent Steel Water Tube Boiler.

The accompanying illustration shows the Torrent steel water tube boiler with the brick casing partly removed. The boiler, which is intended for heating with steam or hot water circulation, is manufactured by Hayes & Falls, 290 State street, Rochester, N. Y. As shown in the illustration, it is intended for hot water, the same design, with trimmings, being adapted for steam. The boiler, it will be noticed, consists of a series of horizontal 1-inch tubes fastened into vertical cast iron headers 3 inches in diameter, the horizontal tubes being, furthermore, connected by short pipes or return bends at the outer ends. These vertical headers at the top are connected by 1¼ or 1½ inch tubes, according to the size of the boiler, with a 4-inch horizontal flow header, F. The lower ends of the vertical headers are connected with the return header R, a horizontal 4-inch pipe. It will be noticed that back of the furnace is a bridge wall, and above the bridge wall is a baffle plate to make the hot gases and products of combustion pass over all the tubes. It is said that circulation in the Torrent boiler is not interrupted by conflicting currents, the water through the lower pipes passing horizontally over the fire, then up and back through upper tubes to the vertical headers, from where it is carried into the main flow header F. There is an arrangement at the back for direct draft when starting the fire. The boilers are brick set and have large clean out doors at the back and front, so that the soot can easily be removed from the tubes. The manufacturers publish the result of a test, stating that the evaporative power of the boiler from steam at 213° to water at 212° was shown to be 11¼ pounds of water to 1 pound of coal. The boilers are made in nine sizes, with grate from 20 x 13 inches to 27 x 36 inches, with heating surface exposed to the fire from 48 to 193 square feet, adapted to carry from 413 to 1737 square feet of direct water radiation and 336 to 1451 square feet of direct steam radiation.



Torrent Steel Water Tube Boiler.

Papers by Master Fitters.

Some excellent articles have been prepared for presentation at the convention of the Master Steam and Hot Water Fitters' Association of the United States, which is to be held at the Broadway Central Hotel, New York City, June 19 and 21. The following are some of the papers, there being others promised, but of which the titles have not yet been made public:

"Warming and Ventilation," by David M. Nesbit, London, England.

"Difference in Radiating Surface Required to Warm Buildings of Poor and Good Construction," by E. P. Bates, Syracuse, N. Y.

"Types of Heating Boilers Used in the United States," by Arthur C. Walworth, Boston, Mass.

"System in Office and Drafting Room," by H. T. Crane, Cincinnati, Ohio.

"Early Reminiscences in Hot Water Heating," by John B Farnsworth, Leominster, Mass.

HEATING NOTES.

The New York office of the Huyett & Smith Mfg. Company has been removed to the Havemeyer Building, 26 Cortlandt street, where General Eastern Manager J. R. Wendover is prepared to talk heating and ventilating apparatus to all interested.

William H. Oakes, formerly manager of the New England branch of the American Boiler Company, Boston, has retired from that position and bought a partnership in the established firm of Buerkel & Co., steam contractors, 28 Union Park street, Boston. Mr. Oakes' successor in the American Boiler Company has not yet been appointed.

The New England Engineering Company, Boston, Mass., issue a circular printed in two colors relating to the Paul system for utilizing and circulating exhaust steam. The circular is prettily printed and the text is of an entertaining sort.

The Gorton & Lidgerwood Company, 96 Liberty street, New York City, manufacturers of the Gorton house heating boilers, will shortly issue a new edition of their book, "Modern House Heating," which bids fair to be in gen-

eral demand. The work typographically will be a work of art and will contain a fund of practical information as to the best manner in which to heat dwellings and other structures efficiently and economically.

JOHN SIMMONS COMPANY, 110 Centre street, New York, are making a large shipment of pipe and fittings to the Chino Valley Beet Sugar Company of California. The pipe, a large portion of which is 12 inches in diameter, and fittings fill several carloads. They are also cutting to specification the pipe for Cornelius Vanderbilt's residence, The Breakers, at Newport, R. I., and for John D. Clarke, 276 Water street, who is installing the heating plant. The fittings for this job are all specially made and some of these pipes are 18 inches in diameter.

D. R. MCJALLUM, formerly manager of the National Hot Water Heater Company and later of the American Boiler Company on the Pacific Coast, is coming to New York to assume the management of the branch office of the J. H. McLain Company, Canton, Ohio, makers of the Canton heater for hot water, steam or hot air.

THE NEWEST ATTRACTION shown by Albert Cryer & Co., heating engineers and contractors, at 85 Centre street, New York, is the No. 327 Richmond sectional boiler. This boiler occupies a space on the floor 5 x 8 feet and stands 7 feet 9 inches high to the top of the steam gauge. The sections are 3 feet wide and 5½ feet high. The boiler shown is the largest size, composed of 12 sections, and is rated to carry 2100 feet of steam radiation or 3300 feet of hot water radiation, and has fire chamber 27 x 57 inches. The boiler is arranged with direct draft or has a full diving return flue. The bottom water section of the boiler forms the bottom of the ash pit, and beneath this three flues are arranged as in a flat top cook stove. The indirect draft sends the smoke and gases to the back and then down to the bottom flue, where they pass to the front at both sides and return to the smoke outlet through a central flue. The boiler is set up complete, with the exception of the asbestos covering, and has a steam gauge and automatic draft regulator.

IRON, STEEL OR BRASS PIPE is bent into any shape desired by the Brooklyn Tube Bending Company, 48 and 50 Ross street, Brooklyn, N. Y., a specialty being made of galvanized coils. They have special patented machinery for the purpose and furnish coils for radiation. They make coils to be used for water heating in connection with furnaces where they are suspended over the fire and the water passes through them. They also make coils for heating water in tanks where the coils are immersed in the tanks and steam is passed through them.

C. F. GESSERT, 42 Dey street, New York, has just completed a renovation of his showroom, and is about to make a fine display of radiators, direct and indirect; flue, prime and extended surface for steam and hot water

THE SYSTEM of heating by steam and the method of installation used in the United States are attracting considerable attention abroad, and the American Boiler Company of 94 Centre street, New York, frequently prepare plans for buildings on the other side of the water. A feature of the plans which their engineer, W. A. Russell, makes is to have the flow pipes distinctly marked with red and the return pipes all marked in blue, making a very pretty effect.

A. S. LIGHT & Co. are a new business firm who will soon make their appearance at Saginaw, Mich. The company will do steam and hot water heating and plumbing and have rented the upper store of the D. H Jerome Building on Court street, which they will open about May 1.

THE CHICAGO ENGINEERING & SUPPLY COMPANY are to move from 108 Lake street to more commodious quarters at 167 and 169 on the same street. The company have the agency for and will carry a full stock of the Standard Radiator Company's goods.

THOMAS E. CRONE, manager of the American Boiler Company's New York office, has been in Chicago for a few days.

THE CHICAGO OFFICE of the Holland Radiator and Mfg. Company will be moved May 1 from 89 to 75 and 77 Lake street.

BLAKE & WILLIAMS, manufacturers of and contractors for steam and hot water heating and ventilating apparatus, will move to 186 and 188 South Fifth avenue, New York, about May 1. They have taken a large six-story building and will put in new pipe cutting machinery and increase capacity in their line of work.

CHARLES A. LATHROP, New England manager for A. A. Griffing Iron Company, reports himself now "at home" to all steam fitters at his Boston headquarters, 177-179 Fort Hill Square.

A GREAT DEAL is claimed by the Peerless steam house heater people for the simplicity, uniform heating power and cheapness of their apparatus. Their catalogues contain many excellent testimonials from people using the heater. George H. Bell & Co., 114 and 116 Nassau street, are sole agents for the United States.

THE LAST NUMBER of the German Valley *Quarterly*, German Valley, N. J., for April, 1894, contains an illustration and full description of the Florida heater, for which the F. D. Stephens Company are general agents for central and northern New Jersey.

FRANK W. SOMERS will soon move to his larger and more commodious quarters, 34 Dearborn street, Chicago, where he will have the entire store in which to show samples of the Bundy radiators and specialties. A. A. Griffing Iron Company were compelled to give up their place at 88 Lake street, as the half store there occupied was not large enough.

AMONG newly chartered corporations in New York State is the Queen City Radiator Company of Buffalo, of which the directors are W. F. Bryant, Orrin Bryant, Wm. H. Harrell of Buffalo and others. Capital, $300,000.

THE NEW YORK WARMING & VENTILATION COMPANY, with a capital of $50,000, have been incorporated at Albany, N. Y. The directors of the concern are W. F. Wolf of Boston, H. M. Caswell of Troy, N. Y., and Wm. H. Knowlson of Peekskill, N. Y.

ARTICLES have been filed with the Secretary of State for the incorporation of the Milwaukee Steam Heating & Electric Construction Company, at Milwaukee, Wis.; capital, $2500; incorporators, Henry Jane, George C. Kuntz and George Crooks.

SECRETARY GEORGE H. REYNOLDS of the Master Steam and Hot Water Fitters' Association moved yesterday to his new quarters, Rooms 324 and 325 Broadway Central Hotel, at 667-677 Broadway, near Bleecker street, New York. This will be his headquarters until the convention in June.

THE S. WILKS MFG. CO., 115 to 123 South Clinton st., Chicago, have issued a 28 page catalogue of the Wilks hot water heaters, steam generators, steel tanks, &c. The water heaters shown cover quite a variety, from small sizes for conservatories, baptisteries, poultry houses, carving tables, &c., to large ones for heating water for hotels, bath houses, apartment buildings, &c., and for heating dwellings, churches, stores and large buildings of all kinds. The large sizes are self feeders, being provided with a coal magazine. These water heaters are of a peculiar type, the fire being completely surrounded by water and the motion of the water being entirely vertical. Hot water tanks as manufactured by this company are either upright or horizontal. The Wilks steam generators, for heating dwellings, stores and large buildings, or for cooking feed, &c., are provided with coal magazines. Both the hot water heaters and steam generators are arranged with sad iron heaters around the base when desired. The catalogue thoroughly explains the construction of the company's heaters, gives full price-lists and also presents a large number of testimonials from those who have the heaters in use.

THE FOWLER RADIATOR & MFG. COMPANY is a new organization at 435 North Broad street, Philadelphia, Pa., who will continue the radiator business which was formerly conducted by H. Belfield & Co., who make a specialty of steam and water valves. The demand during the past season for their radiators has exceeded their facilities for production, and arrangements are being made for an enlargement of their plant such as will enable them to fill their orders promptly. They say that the Fowler radiators have already taken a place in the front rank, and the result of their last year's business has been very gratifying.

Thos. Fletcher of Warrington, England, writes to the *Gas World* as follows: "It is not generally known that the quality of ordinary writing ink depends on the gas supply. The best black inks are made from galls, and the use of vegetable (oak) galls has been superseded for many years by dried animal galls, which come almost exclusively from China. These are roasted in revolving cylinders, in charges of about 2 hundredweights, at a temperature of 300° F., and as the exact temperature is a matter of the utmost importance, gas is exclusively used for the purpose. The burners have an average consumption of 200 cubic feet per hour, and in an ordinary ink manufactory the work is considerable. As with mustard, the demand is created rather by what is dried up and wasted than by what is used. This is one of the apparently small industries which are in reality large; and help to swell the receipts of the gas companies for other and more regular purposes than lighting."

The employees of the Passaic Zinc Company's works in Jersey City, N. J., were informed last week that the 10 per cent. taken from their wages last December would be restored to them on May 1.

SCRAP.

THE PROJECT, to which reference was made in a late issue, of erecting a large tin plate works at Washington, Pa., has, we understand, taken definite shape. A company has been organized with a minimum capital of $250,000, all the plans have been prepared for a complete modern tin plate plant, and the ground for its erection has been secured. The town of Washington, Pa., has been fixed upon for its location, and citizens of that place have subscribed for a large number of shares in the enterprise. The actual commencement of building operations will depend largely upon the course of tariff legislation. N. E. Whitaker of the Whitaker Iron Company, Wheeling, W.Va., is at the head of the enterprise, and is said to be backed by some prominent members of the metal trade in New York City.

SAUNDERS, FIELDING & BOND, importers and dealers in tin plates and metals, have removed their office from 284 Pearl street to the Downing Building, 108 Fulton street, New York City. The firm are agents for the Pontymister Tin Plate Works of Newport, Wales. They have also offices at Swanses, Wales, and at Chicago, 419 Ashland Block, in which city they are the selling agents for the Morewood Tin Plate Company of Gas City, Ind.

REPORTS of projected tin plate plants are rife at the present time despite the uncertainty regarding the tariff. A late dispatch from Marion, Ind., announces that a large works, to cost $100,000 and to employ 300 men, is to be established at that place by E. Stanford.

AT MARSHALL BROS. & Co.'s mills, Philadelphia, the demand for black sheets for tinning purposes is crowding the establishment to the limits of its capacity.

ALL the Western tin plate works are reputed to be running to their fullest capacity on orders for American roofing plates. The main difficulty encountered in supplying the awakened demand is that of obtaining enough domestic black sheets. All the mills rolling this product are said to be behind their orders. Many have enough work on their books to keep their rolls in full work until the end of July. This is the case with the Eastern as well as the Western mills.

A WELSH tin plate manufacturer just arrived in New York City speaks of the present situation of the British tin plate trade in anything but cheerful terms. More than half the Welsh mills are idle, and prices are so low that profits have almost reached the vanishing point. Probably 5 cents per box is the outside gained by the average manufacturer, and even this modest profit is not easy to be obtained. Buyers' offers are as often as not below the actual cost of production.

THE United States Consul at Cardiff reports to the State Department a great reduction in the exports of British tin plates for the first quarter of this year, amounting to 22,500 tons, as compared with the corresponding period of 1893. During March this year the United States took only 16,997 tons of tin plates and sheets, while last year the amount for March was 31,334 tons. The exports were diminished to Argentine Republic, Brazil, France, Italy, Russia, Germany and Portugal, and increased to British North America, Australasia and several other countries.

THE MONTPELIER SHEET & TIN PLATE COMPANY of Montpelier, Ind., was incorporated on the 19th inst. with a capital stock of $200,000. The stockholders are Monroe Seiberling and Charles A. Ford of Kokomo, and Carl W. Kolbe, Daniel A. Walmer and David Moser of Montpelier.

Sizes of Furnace Pipes.

BY A. W. GLESSNER,

President of the Excelsior Steel Furnace Company, Chicago.

The time is near at hand when building will commence throughout the country and furnace dealers will begin their annual campaign. It may be opportune, therefore, to call the attention of the trade to the importance of careful figuring in regard to the sizes of furnace pipes, &c., to be used in the work in prospect. A great deal has been written and published on this subject by *The Metal Worker* during the past five years, and it would not be unreasonable to suppose that almost every furnace dealer has a fairly correct idea of the sizes of pipes and registers necessary for the efficient heating of rooms of a given size, but such does not seem to be the case. A short time ago the writer saw an estimate made by a Western furnace dealer for heating an elegant residence in his town, and that he was very anxious to obtain the contract for the heating of this building was shown by the detailed plans and specifications which he had gotten up and evidently submitted to the owner. On the second floor there were six chambers and a bathroom, varying in size from 4 feet 6 inches x 11 feet to 17 x 19 feet, and to heat these apartments the aforesaid furnace dealer had planned to use 4 x 10 stacks and 8 x 12 and 8 x 10 registers, irrespective of the varying sizes of the rooms. Comment on the result of such a job if put in according to these plans would be superfluous.

I append to this article a table which, while only approximate, may be found of considerable value to dealers who have not some such table evolved from their own experience. There is nothing particularly new in this table, but I do not remember having seen it in print in any of the trade journals. Any one using pipe according to this schedule in buildings within 100 miles of the forty-second parallel cannot go very far astray. It will be noticed, however, that comparatively few dealers or furnacemen use quite as large sizes of riser pipes as those referred to in the table, and possibly not a little of the trouble in heating chambers might be traced to the use of stacks too small in size. No table could be made to cover the ever varying conditions under which furnace pipe works, and I would therefore say that this table is based on normal conditions with runs of pipe of usual length and is intended to show the size of registers and pipes necessary to raise the temperature of air from zero outside to 70° on the inside within reasonable time without forcing. The sizes that are marked with an asterisk are those recommended for general use. The larger the register the less resistance to the flow of the heated air, but sizes mentioned will produce good results.

Size of register.	Equivalent in round or leader pipe.	Equivalent in square or riser pipe.	Cubic feet of space on first floor same will heat.	Cubic feet on second floor.	Cubic feet on third floor.
	Inch.				
6 x 8	6	4 x 8	400	450	500
*8 x 8	7	4 x 10	450	500	560
*8 x 10	8	4 x 10	500	850	880
*8 x 12	8	4 x 11	800	1,000	1,050
*9 x 12	9	4 x 12	1,050	1,250	1,320
*9 x 14	9	4 x 14	1,050	1,350	1,450
*10 x 12	10	4 x 14	1,500	1,650	1,800
*10 x 14	10	6 x 10	1,800	2,000	2,200
10 x 16	10	6 x 10	1,800	2,060	2,200
12 x 14	12	6 x 12	2,200	2,300	2,500
*12 x 15	12	6 x 12	2,250	2,300	2,500
*12 x 17	12	6 x 14	2,300	2,600	2,800
12 x 19	12	6 x 14	2,300	2,650	2,800
*14 x 18	14	6 x 16	2,800	3,000	3,200
*14 x 20	14	6 x 16	2,900	3,000	3,200
*14 x 22	14	8 x 16	3,000	3,200	3,400
*16 x 20	16	8 x 18	3,600	4,000	4,250
*16 x 24	16	8 x 18	3,700	4,000	4,250
*20 x 24	18	10 x 20	4,800	5,400	5,750
*20 x 26	20	10 x 24	6,000	7,000	7,450

The prolonged conflict in Brazil has at length been brought to a period. Official dispatches confirm the fact of the sinking of the insurgent battle ship "Aquidabsn" by a federal torpedo boat in the harbor of Santa Catharena on April 16. Admiral Mello has given up the struggle, and, with five ships, has surrendered to and obtained asylum from the Argentine Government at Buenos Ayres. The revolutionary movement is said to have completely collapsed.

Philadelphia business men complain bitterly of the disadvantages suffered by their city from the discrimination practiced by the railroads in the matter of freight rates. Concerted action will be taken by them, it is said, with a view of improving and enlarging the transportation and shipping interests of Philadelphia, which have suffered severely of late.

The delay in the construction of the new dry dock at the Brooklyn Navy Yard is attracting the dissatisfied attention of the Government. It is very probable that the present contract with Mr. Gillis may be revoked, and the Government may either carry on the work itself or allow another private firm to complete the dock, which is urgently needed for the ships of the new navy.

A shipment of 2800 tons of bituminous coal was made last week from Baltimore to Montreal, Canada, although a duty of 60 cents a ton and freight charges bring the price of the fuel considerably over that of the Nova Scotia product. Some of the Canadian manufacturers are, however, dissatisfied with the domestic coal, and it is for these parties that the present shipment, the first of its kind, has been made.

The depression in business and the accompanying restriction of imports is clearly illustrated by a statement of Custom House receipts since the beginning of the fiscal year, published in the *Journal of Commerce*. These receipts are shown to have fallen off $41,224,363, or nearly 40 per cent. as compared with those of the corresponding portion of the last fiscal year.

Press Working of Sheet Metals.—V.

BY OBERLIN SMITH.

Bending Processes.

Following a natural order, we come next to forming or bending processes, where the metal has its surfaces pushed out of their original planes into some new shape, but where the thickness is supposed to be not materially altered, except where it is incidentally made thinner in certain spots by being stretched, &c. In Fig. 177 is shown a V-shaped pair of bending dies and beneath them a straight plate of metal, *a*, together with the same as it appears after bending, at *b*. The dotted line *b'* shows where the dies tried to bend it and the black line *b* its final position as assumed by its own elasticity. This, of course, varies with the material, a piece of lead or even copper remaining very nearly in the same shape as the die which forms it, while iron, mild steel, hard brass, &c., in the order named, require such a die to be of a more and more acute angle, as the metal approaches nearer the character of a spring.

In Fig. 178 is shown a pair of bending or forming dies which are removed one step further from the simplicity of the first named, giving two bends to the work instead of one. Here the same difficulty occurs in regard to the edges springing part way toward their original shape after leaving the die, as shown again by the lines *b b*. It is not therefore possible with a die of this kind to produce edges which are exactly square with the main body of the plate. An approximation may, however, be sometimes made by bulging upward the horizontal surfaces of the dies, as shown by the dotted lines in Fig. 178, to an extent not greater than is suited to the elastic limit of the particular pieces of metal used. The die therefore attempts to make the work somewhat concave upon the bottom, as at *c*, which forms the corners at a sufficiently acute angle to approximately counterbalance the tendency to spring open; so that when the bottom has sprung back flat the edges will stand up perhaps nearly enough at right angles thereto. To place practical dependence upon this system, however, requires uniform blows by the press and uniform elasticity in the metal.

Forming Processes.

In Fig. 179 is shown a pair of round forming dies, where a flat circular blank, *a*, is laid in the recess *m*, which acts as a gauge merely for locating it centrally. It is then pushed by the upper die, or punch, U through the parallel opening *n*, and falls beneath the dies—being stripped off the punch when the same is ascending by the sharp stripping edge *o*. At *b* is shown the shape of the work when in a half way stage of the operation, its final condition being as at *c*. With dies of this kind the edge of the work cannot be very deep in proportion to its diameter, on account of the wrinkles which evidently attempt to form when the circumference is reduced. It is true that these incipient wrinkles can be somewhat smoothed out by allowing the punch and die to fit tightly enough to confine the metal to its original thickness—providing this thickness came uniform, which it usually does not in practice. In doing this, however, the metal of the edge is lengthened in certain spots in a vertical direction, which causes a jagged edge. If the depth is too much increased the wrinkles so fold upon one another as to tear the metal entirely away at certain places. The remedy for this will be considered later on under the head of the drawing process. With metal like ordinary tin plate, in diameters of not less than 2 inches, a width of edge from $\frac{1}{8}$ to $\frac{1}{4}$ inch can usually be obtained in plain forming dies without objectionable wrinkles.

With cylindrical work like that in question, and also with elliptical work (which resembles it by having a convex contour with an edge extending all around) the outward springing of this edge does not occur to an objectionable degree, as it does with rectangular work having two separate and unconnected edges, like that shown in Fig. 178. This is because the edge C forms itself into a hoop, as it were, to confine itself from moving outwardly, which it cannot do when released from the die without actually stretching in a circumferential direction; and this evidently can occur but in a very slight degree.

In Fig. 180 is shown a pair of forming dies for turning an edge upon an internal instead of an external circular contour. These take a perforated blank, *a*, and open out the hole, turning it downward into a cylindrical shaped edge, as at *b*. If an attempt is made to get this edge too wide certain cracks will appear, as at *c c*, &c., in the picture. As the edge in opening outwardly increases its circumference, it will not stand more than a certain amount of tensile strain, the stress here being of exactly an opposite character to the compressive one which forms the wrinkles in work like that in Fig. 179.

Embossing.

In Fig. 181 is shown one type of a pair of embossing dies, so called. The word "embossing" is used in this treatise, and very generally in the sheet metal trades, to denote a small degree of forming or bending at various points upon the surface of a piece of sheet metal, the location of which usually tends to show in top view a figure or design of some kind, decorative or otherwise, as for instance pictures, symbols, lettered inscriptions, &c. In such work the metal is pushed downward or upward more or less at various points into ridges and grooves, but not to a sufficient extent to tear it apart. The tendency is evidently to so tear it, as its outer edges are maintaining a rigid resistance against inward flow (except in certain forms of the drawing process) and the metal has therefore to elongate where forced to take a shape whose cross section shows a longer profile line. This is shown by the section of the piece of embossed work, *b*, which is longer in profile than is the blank from which it was made, *a*. In the case given I have represented a pair of circular dies with two annular grooves sunk in L, corresponding ridges projecting from U. This is a design sometimes used upon the heads of tin cans, &c., its object being partly to make them stiffer and perhaps partly for ornament. Such embossing, however, is merely typical of an infinite number of designs which may be thus stamped upon ductile metal. The word "embossing," as applied to this process, should not be confounded with the same term as sometimes used to designate the process known more properly as coining, to be described further on.

In Fig. 182 is shown a broken away vertical section of one groove and ridge of a pair of embossing dies, where the flat surfaces have approached each other within a distance messured by the thickness of the metal, represented by *m*. Theoretically the space between upper and lower die might properly be this thickness, *m*, at the points *n*, *o* and *p*, as the metal would then exactly fill between at all points. Practically, however, it is better to give an embossing die clearance at such points as *n* and *o*, letting the metal follow the "tight points" to suit itself, as in the picture. This is desirable, because some of the metal may be a little too thick, or dirt may accumulate in the dies, in either of which cases there would be a jam between the points *n* and *o*, which would prevent the dies coming down home, or, at any rate, would require a great deal more pressure to do the work. Another reason for this clearance is the practical difficulty of the die maker being perfectly sure that there is space enough everywhere, unless he follows the method here given, of being sure there is enough by having too much. It is customary to give a little clearance at *p* also, but this is not of so much importance, as a jam at that point would simply prevent the flat surfaces from coming together quite so close.

A simple method devised by the writer and long practiced by those working under his instructions for ascertaining the clearance of forming and embossing dies is to lay pieces of small lead wire, whose diameter may be about two times *m*, across the dies at the various points requiring a test. Between these points small pieces of the sheet metal to be used, whose thickness is *m*, are laid upon the lower die to act as blocking, so that the proper stopping point of the upper die may be insured. The press ram is then brought hard down, with the result of the lead being smashed out to the varying thicknesses represented by the spacing of the dies and as shown in Fig. 183. It is evident that all such points as *n* and *o* ought to be thicker than *m*, and this is generally easily determined by the eye. Such points as *p* must, of course, never be less than *m*, and may be a little more.

Embossing and Cutting.

Almost all the various processes of forming and embossing may be combined with cutting wherever the work is of suitable shape. The tools for conducting such operations are usually termed "combination dies," although the term is not very definite, being sometimes used, as before described, for the combining of two or more sets of cutting edges. In Fig. 184 is shown in vertical axial section a pair of combination dies such as are very extensively used for producing fruit can tops, as shown in section at *a*, and bottoms, as shown with embossed groove *a'* or plain at *a''*. In practice these dies are assembled in separate pieces to some extent to insure cheapness, durability and facility of repairs, but they are here depicted in conventional form. It will be seen that the outer cutting die has the female at the bottom as well as the inner one, a result which was not obtained in Fig. 166, Chapter IV., where the work remained flat. In this case the latter part of the upper die's descent cuts the central hole, while the forming of the edge at *b* and the embossing of the groove at *c* is taking place. It will be noticed that the turning upward of the inner wall of this groove causes a

Correction.—In the chapter of this article on page 40 of *The Metal Worker* of April 14, column one, twentieth line from the bottom, the letters "S" and "C" should be transposed, "S" properly being the sprue and "C" the casting.

tendency to crack, as in *b*, Fig. 180, although in practice it is not made deep enough to produce this effect. Such action does not take place in *a'*, because the stretching action is resisted by the continuous surface in the center, which is retained in the case of this can bottom by removing the central cutting punch *d* from the upper die. Should a plain flat bottom be desired, as at *a''*, the embossing punch *e* is also removed.

A knockout ring is shown in upper die at K and in lower die at K'. They are unnaturally given in closed position (as they would be were the dies shut together) merely to show better the general contour of the sectional view. Sometimes what is called an

scribed varies considerably, according to the character of the work and the condition of the dies. For given pieces of metal, however, it frequently happens to be a good deal more than for the cutting operations performed upon the same.

Assembling.

Analogous with forming processes proper, there are various cases where the assembling of two or more pieces is done, oftentimes upon the same general principle as the riveting down of an eyelet, or a rivet, which has been passed through two pieces of paper or metal. In general, some piece of metal which has previously been brought to shape by dies or otherwise

edges so shallow as not to form stiff trussea in themselves. The die maker is often blamed for work thus coming from the press twisted and sprung, so that it is impossible to make it lie flat upon a plane surface. Generally, however, a result of this kind is entirely owing to its design; and Dame Nature, rather than the die maker, must be blamed for one of the most provoking and perplexing problems which the die user is called upon to solve.

Mechanically the cause of this warping is due to the middle of the stamped sheet of metal being too small for the outside thereof, so to speak. This occurs when the central parts have been embossed or otherwise drawn together and put under a tensile strain, while

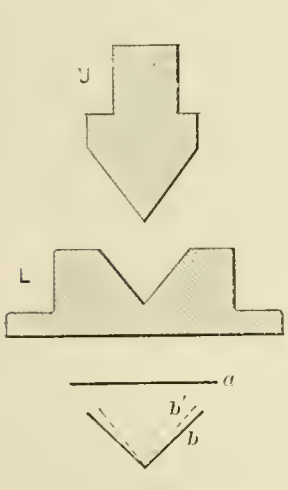


Fig. 177

PRESS WORKING OF SHEET METALS.

"edge knockout" is used, instead of K', consisting of a thin ring rising in the groove K'' and pushing against the edge of the work, instead of underneath its flat surface. This ring K'', if driven up by strong springs, acts in some degree as a spring drawing attachment (to be described later on) and serves to smooth out the slight wrinkles which usually otherwise appear in the edge of the work. The knockouts described are generally driven by springs, but sometimes by pins extending through the dies and attached to or pushed by certain positive action knockout devices.

The speed at which forming and embossing work is done is of little consequence, as in practice the ram speeds of the presses in common use are none of them fast enough to tear the metal by moving it more rapidly than its molecular inertia will permit. The pressure required for the processes above de-

is driven tightly, or perhaps dropped loosely, into or on to some other piece or pieces, whereupon they are all fastened together by some auxiliary forming process which bends or forms certain edges or surfaces in a manner best adapted to locking the various pieces permanently together.

Involuntary Processes.

In addition to the humanly invented processes we have been considering, there are sometimes developed others, which, to a careless observer, might seem to emanate from the brain and hand of his Satanic Majesty. Among what may thus be called involuntary processes is the very annoying one known as warping, which occurs especially in the products of embossing and forming dies, as well as to some extent in drawn work also. The most favorable conditions for its occurrence are thin metals, large diameters, and

the average circumference of an outer zone, near the edges, has not been correspondingly reduced, and therefore does not assume the shortest distance around its course, which would naturally lie in a plane. A remedy is sometimes found by altering the design so that this outer zone may have various ribs and corrugations running approximately in a radial direction toward the center, such corrugations tending to take up the surplus metal in a circumferential direction. These additional features can often be added by a judicious designer in a way to serve a decorative purpose. A similar warped effect can obviously be produced by letting the middle of the metal alone and stretching or otherwise increasing too much the area of the edges. This, alas, is often done by forming dies when turning a narrow vertical edge around a large thin blank. Such action is due to imperfect "upsetting,"

where the circumference is reduced, and perhaps also to a too tight squeezing of the edge between the dies.

The converse of the conditions above mentioned occurs when the middle part of the sheet is too big for the outside, as is the case in any dished or saucer shaped work. This is often seen in bottom of buckets, &c, which have been somewhat bulged and which can be "flopped" back and forth, always staying in a position at either side of the plane of the outer zone of the metal accordingly as they are put. In such case the said outer zone is pushed outwardly by the central parts and is therefore in a taut condition, which tends to make it stay flat rather than otherwise. If that surpassingly skillful artisan known as the "saw maker" were to tackle a sheet of this kind, he would soon flatten it by hammering it near the edges. If, on the contrary, he hammered it in the middle, it would be because the conditions described in the last paragraph were present.

For the various forming and embossing processes described in this chapter, almost any type of press may or may not be suitable, according to circumstances. The type least likely to meet all conditions is, perhaps, a drop press, which usually has the peculiarity of a faster moving and more loosely fitting ram than have other presses. These machines, however, are especially adapted to some kinds of embossing work, and are sometimes used for forming, particularly in producing shallow pans, plates, trays, &c., in tin plate and sheet iron. In recent years they have been, for these latter functions, superseded to a considerable extent by drawing presses.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

Among recent contracts obtained by H. Sandmeyer & Co., Peoria, Ill., was one for ventilating the Streator (Ill.) school, a ten-room building that cost $35,000. Other contracts are for the Dickson dry closets in schools at Highland, Ill.; Effingham, Ill.; Tuscola, Ill.; Pana, Ill.; Lafayette, Ind., and Gilman, Ill. The ventilated flushing closet, which is also meeting with much favor, is contracted to be put into the Marshalltown (Iowa) High School and in the Streator (Ill.) school.

Coe & McMillen, Monticello, Ill., have secured a contract for heating and ventilating the school building at Monticello for $1872.72. They will use a 54-inch by 14 foot tubular boiler, made by the Kewanee Boiler Company of Kewanee, Ill., and Perfection radiators for the direct and Excelsior stacks for the indirect, it being a system of natural ventilation. The work will be done by C. W. DeForrest, formerly of E. K. Lockwood & Co. of Norwalk, Conn.

Carson & Co., Danville, Ill., have the contract for plumbing in the school building at Monticello, Ill., which will consist of a No. 2 Wolff range closet and urinal and a drinking fountain on each floor. The bid for the work was $561.

The J. H. McLain Company, Canton, Ohio, have secured an order through their San Francisco office for two Humber hot water heaters for the Whittier School, a State institution at Los Angeles, Cal.

T. B. Dewees, Phœnixville, Pa., has received the contract for roofing and plumbing for two new houses on Church street. He also has the contract for roofing two new houses at Spring City.

Plans are being prepared for the erection of an $8000 armory at Detroit, Mich., to be lighted by gas, heated by steam and to have a plumbing system.

F. J. Wood is to erect a store and office building at a cost of $20,000 at Grand Rapids, Wis., to be heated by hot water and have a plumbing system.

The School Board of Meredith, N. H., have appropriated $700 for a steam heating system for the school house.

John Simmons Company, 110 Centre street, New York, are furnishing to Edward P. Clarke, 126 Liberty street, New York, a hot water boiler and the heating pipes and radiators, to be exported to La Guayra, South America.

The Council of Providence, R. I., have appropriated $3500 for a heating system for the new central police station.

An improved heating system will be installed in the Winona Seminary, recently purchased by the Sisters of St. Francis of Winona, Minn.

The Davis Company of Moline, Ill., have been awarded a contract for plumbing the new High School Building, their bid being $1300.

Fay & Scott of Dexter, Maine, have the contract for installing a steam heating plant in Union Hall at Pittsfield, Maine.

J. Glandfield & Son of Dixon, Ill., have the contract for the erection of a school house to cost $19,000, at Oregon, Ill., which will have a system of heating and ventilating not included in their bid.

Wright Brothers of Ipswich, Mass., are installing a hot water heating plant in the residence of E. A. Wright, at Hamilton, Mass.

The board who have in charge the erection of a home for the feeble minded at Lapeer, Mich., have awarded the contract for heating to the Eureka Heating Company of Saginaw, Mich., for $7140, and the contract for the plumbing to William McFadden of Detroit for $2497. The contract for sewerage went to Perry & Hurley.

T. J. Tuomey, Seventy-second street and Third avenue, New York, is doing the plumbing work in the office building being erected by J. Lyons at Fourth street and Broadway. He is also remodeling the plumbing system in the old *Herald* building, at 194 Broadway, and is fitting up a storage warehouse for Sonn Bros. at 385 and 387 Washington street.

The Hub Plumbing, Heating & Stove Company, Clinton, Mass., are putting in a system of water works in the town of Boylston, Mass.

The contract for supplying the heating apparatus for the Young Men's Christian Association building at Springfield, Mass., was awarded to the Phillips Mfg. Company of that city, whose bid was $3300. They will use two No. 4½ Mills boilers of 37 horse-power each.

The J. F. Pease Furnace Company of Syracuse, N. Y., have recently secured through their agent at Harrisburg, Pa., E. E. Palmer, the contract for warming and ventilating the six-room annex to the Maclay Street School at that place.

Architect G. L. Harvey, Chicago, is making plans for an apartment building for Dwight S. Bryant, to be built on Forty-seventh street and Prairie avenue. The apartments will have all modern improvements, exposed plumbing and hot water heat.

The Baker & Smith Company, 193 to 197 Van Buren street, Chicago, are to install a tubular boiler and necessary radiation for steam heating in the new Post Office block, Fifty-fifth street and Monroe avenue.

The Union Iron Works & Steam Heating Company, Altoona, Iowa, have the contract for placing a Gurney double crown heater in the residence of T. D. Foster.

A low pressure system of steam heating will be placed in St. Mary's School, Burlington, Wis., by A. Zweibe & Son. One of the United States Heater Company's Hecla boilers will be used.

McGinnis, Smith & Co., Pittsburgh, Pa., recently installed the hot water heating plant in the Black & Bayard office building, at Pittsburgh, Pa. They used two No. 25 Gorton hot water boilers connected with one flow main and report satisfactory operation and a good circulation with a low temperature at the boiler.

Dugan Brothers, Salem, Ore., are installing a Royal hot water heater in the Oregon Soldiers' Home at Rosebury. The same firm have also the contract for doing the plumbing.

Bids will be received up to May 2 for the plumbing, gas fitting, steam heating and ventilating apparatus for the city and county hospital at St. Paul, Minn.

Architects Thomas & Rapp, Chicago, have received instructions from the Board of Education of South Evanston, Ill., to rebuild the school house recently destroyed by fire. The building is to be heated with steam and furnished with the latest improvements in ventilation. It will cost about $40,000.

Architects Beers, Clay & Dutton, Chicago, have designed for John R. Geary a four story apartment house to be built on the east side of Okenwald avenue, south of Forty-fourth street. The interior will be divided into eight apartments of seven rooms each and be heated by steam.

Architect Alfred Smith, Chicago, has prepared plans for a residence to be erected at 375 Ashland avenue. The front will be built of stone and the interior finished in hardwood and heated by hot water.

Architects Flanders & Zimmerman, Chicago, have prepared plans for a store and apartment house to be erected at the southwest corner of Fifty-fifth street and Monroe avenue, to be heated by steam.

Architects J. Sidney Villere & Co., Chicago, are preparing plans for a three-story apartment house to be built at the northwest corner of Deming and Hampton Courts, by J. Frank, to be heated by steam.

The Bridgeport Steam Heating Company, Bridgeport, Conn., have secured the contract for placing the hot water apparatus in the new mansion of Elwood Stokes Hand at Southport, Conn.

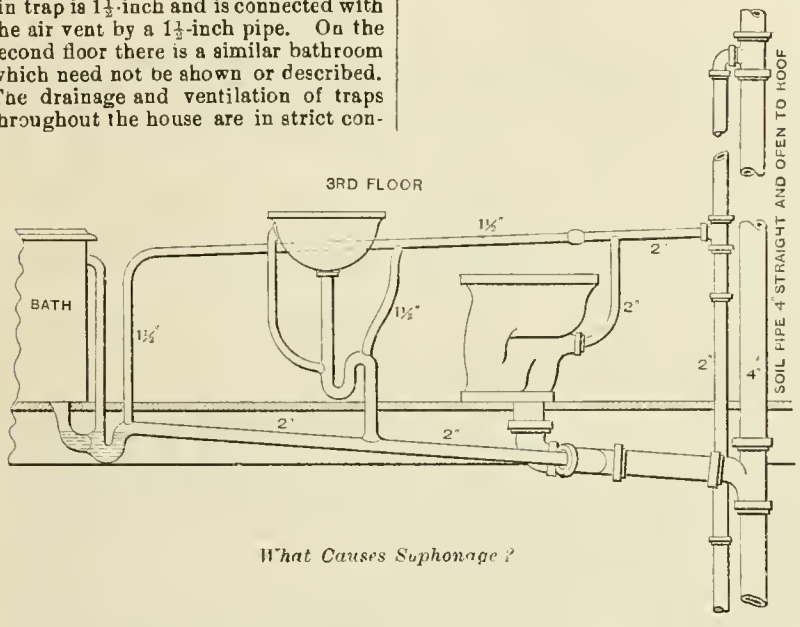
Architect DeWitt Taylor Kennard, Chicago, has designed for H. C. Brachvogel a three-story apartment house to be erected on Vincennes avenue, near Forty-eighth street, to be heated by steam.

The contract for the steam heating and plumbing in the Planters' House, at Pekin, Ill., which is to be transformed into a modern office building, was awarded McGreggor & Co. of Bloomington, for $800.

PLUMBING and GAS FITTING.

What Causes Syphonage?

From INQUIRER, *New York*.—Herewith is a sketch of the plumbing of a three-story house showing the pipes for drainage and ventilation. The water closet is of the ordinary washout kind, having a 2-inch air vent of lead pipe connected with a 2-inch iron pipe. The waste pipe of the bathtub is 2-inch and runs into a 4 x 2 Y that connects with the main soil pipe. The bath trap is 2-inch and has 1½ inch air vent. The basin trap is 1½-inch and is connected with the air vent by a 1½-inch pipe. On the second floor there is a similar bathroom which need not be shown or described. The drainage and ventilation of traps throughout the house are in strict conformity with the Board of Health rules. The job has been done in a workmanlike manner, no contractions of areas in any of the pipes or connections. All of the system is perfectly free from stoppage or solid joints or forgotten oakum. Will some of the thoughtful readers of *The Metal Worker* explain why the traps of the baths and basins are syphoned by the use of the water closet either from a prolonged flush or ordinary use?



What Causes Syphonage?

Plumbing Trade in Brooklyn.

Brooklyn plumbers generally report themselves as being fairly busy. The jobs in hand are, however, almost exclusively of small proportions. Householders are this season only having just such work done as they find to be absolutely necessary, and there is said to be a marked absence of the "cream" orders which usually develop in the early spring. The business depression of the past nine months seems to have touched all classes more or less, and this is reflected in the plumbers' order books as well as in those of the supply houses. In illustration of the situation, one of the most prominent plumbers of the city, who is accustomed at this season to handling contracts for work amounting individually to thousands of dollars, says that he looks on a $150 or $200 job at the present moment as quite a large one. Even these are comparatively scarce. In the spring he usually has orders for from eight to a dozen porcelain bathtubs, but this year there has not been a call for a single one. Collections, moreover, are not easy, and a good deal of even the smaller work is being taken on the installment plan of payment. The amount of building now in hand in Brooklyn is comparatively insignificant. Nevertheless, the hope that "springs eternal" prompts to the expectation of a development of better things in the summer, with a very good fall business, "provided the tariff bill is meanwhile passed or smashed," for there is plenty of work waiting for the time when money shall again flow in its accustomed channels.

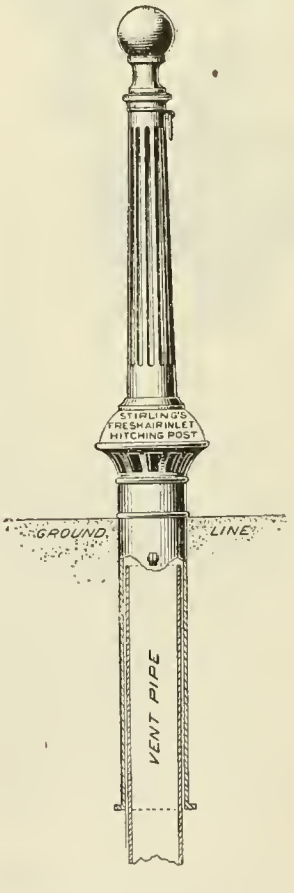
Newark, N. J., Plumbers.

The regular meeting of the Master Plumbers' Association of Newark, N. J., last Tuesday evening, found an attendance of 50 members and a very interesting meeting was the result. The committee who had waited upon the plumbers who had made an extraordinarily low bid to the city for plumbing and steam heating repairs for the coming year, reported that the bids had been withdrawn and the association expressed their gratification at the good work accomplished. Another feature of the evening was the appointment of a committee of five to make arrangements to celebrate the first anniversary of the association, which occurs on June 27. President Berla was very deliberate in selecting the members for this committee, and a number of pleasantries were exchanged during his deliberations. Treasurer Jacobi was selected for chairman.

ON A RECENT VISIT to the Department of Building of New York City it was discovered that in the plumbing and ventilating department the corps of engineers were more than two days behind in considering the plans that had been submitted to them for approval, and that these plans included a number of large and high class buildings. While this information comes from the Department of Plumbing and Ventilation, it shows that other lines of trade will be equally busy in the construction of the buildings and of the various appliances that will be needed in them. Until lately comparatively little was doing in this department, and Henri D. Dickinson looks on the rush of work at the present time as of more than ordinary importance in all lines of trade.

Fresh Air Inlet and Hitching Post.

The accompanying illustration shows a novel combination of fresh air inlet and hitching post made by Edward M. Stirling, 85 Market street, Newark, N. J. The construction and application of this device are so clearly indicated in the engraving that very little description is needed. It consists, as shown, of an ordinary hitching post, with perforations near the bottom connecting with the inner pipe that forms the lower end of the post, and fits over the top of the fresh air inlet from the house drain at the foot of the soil and waste pipe system on the house side of the trap. It is particularly mentioned by the manufacturer that this inlet is not liable to be clogged by dirt and become

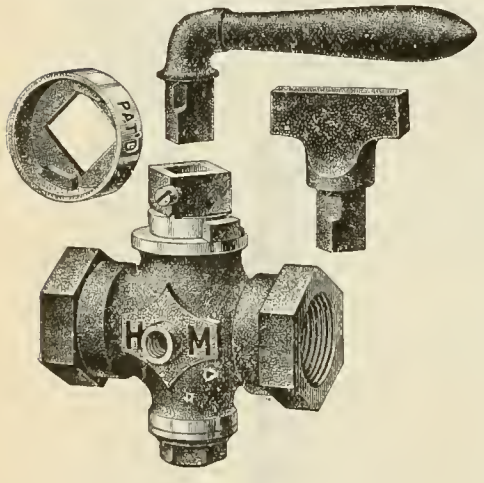


Fresh Air Inlet and Hitching Post.

useless, and does not present a conspicuous hole to be filled up by the mischievous small boy.

The Mueller Stop and Waste Cock.

The H. Mueller Mfg. Company of Decatur, Ill., have just put on the market a new stop and waste cock which has some special features which will be appreciated by plumbers. An illustration of the device is herewith given. It is so constructed that it can be changed instantly from right hand to left hand, or *vice versa*. The top is interchangeable, permitting the use of either lever handle, tee handle or square rod. The top of the cock is supplied with a cap that fits over the square of the plug, thereby preventing dirt or sand from working down alongside the plug and wearing out the cock. The cap is provided with two heavy lugs cast on the under side, and these coming in contact with a heavy lug cast on the body of the cock form a very strong and substantial check. These cocks are made only in straight way from ½ inch



The Mueller Stop and Waste Cock.

to 1 inch inclusive. They are designed for indoor work, but can be used for outdoor work equally well. The company state that these cocks are of a specially high grade of workmanship. The company also make a complete line of standard patterns of cocks for outdoor work, both in straight way and round way. All their brass goods are made of red brass metal and extra heavy pattern, and are tested to a pressure of 200 pounds. These goods are branded "H. M." A special claim for the cock herewith illustrated is that the plumber need not carry such a large stock, because he can use this make of cock for either right or left hand, lever handle, tee handle or square rod.

TRAPS AND VENTS.

The Brooklyn master plumbers will, it is expected, send a full and representative delegation to the forthcoming national convention at Detroit.

R. M. Wilson, Rome, N. Y., issues a catalogue of his well-known line of plumbers' supplies. In presenting the catalogue for 1894 the manufacturer calls special attention to his complete line of bathtubs. The Wilson patented aluminum and all copper sanitary bathtubs are especially alluded to. They are made from pure aluminum and Lake Superior copper, and have no enamel or paint. Other goods particularly noted are his folding copper lined bathtubs, copper range boilers, &c. The volume, which contains over 100 pages, begins with notices of bathtubs, followed by range boilers, copper balls, shower baths, bath and basin cocks, traps, lavatory brackets, miscellaneous fittings, ferrules, brass fittings, valves, pulls, flush tanks and closet seats. At the close is an alphabetical index.

Zalmon Goodsell of Bridgeport, Conn., one of Connecticut's representative plumbers, is being boomed by the local papers for Governor of the State. Those who have met him at the State and national conventions of master plumbers can testify of his fitness for the office.

J. E. Zimmerman, representing the Ideal Mfg. Company of Detroit, Mich., manufacturers of the Ideal sinks and tanks, recently shed the light of his presence upon the Boston trade.

The popularity of the smoke test for finding leaks in plumbing systems is shown by the number of plumbers who are securing apparatus for the purpose, among whom are L. D. Hosford, 43 Beekman street, E. A. Moody. 939 Sixth avenue, T. J. Daly. 1688 Broadway, and Ryan & Holmes, 280 Boulevard, New York, and George B. Lewis of Brooklyn. The machines used are of English manufacture and were purchased from the importers, the Myers-Sniffen Company, Limited, 46-48 Cliff street, New York.

W. P. Rose & Brother have opened a plumbing shop at 3620 Jacob street, Wheeling, W. Va.

The master plumbers of Holyoke, Mass., met at C. P. Lyman's office last Saturday night and talked over matters connected with the convention of the State association of master plumbers to be held in the city May 9. The meeting will be held at the Hamilton and will end with a supper at the hotel in the evening. About 75 members of the association are expected from out of town and all the local members will attend. The most important business will be the election of officers and there will be reports of committees appointed at the last meeting to secure legislation on certain points connected with the business. Discussion will be held on the plumbing ordinances adopted in several cities.

Fred. C. Barrett has moved his plumbing establishment to 24 Taylor avenue, Westfield, Mass.

The Board of Plumbing Examiners of Holyoke, Mass., are Dr. G. H. Smith, Peter Murray and Dennis O'Leary. They are now prepared to examine all who apply for licenses, and hope to have all applications in by May 1, after which date Inspector Murray will enforce the recently passed plumbing ordinances.

The R. T. Connell Plumbing & Heating Company have been incorporated, with a capital of $20,000, at St. Joseph, Mo. The incorporators are R. T., D. C. and Margaret Connell.

Wright Brothers are a new plumbing firm in the Jones Block, at Ipswich, Mass. They will carry a full line of steam and hot water heaters, stoves, furnaces and ranges.

Milton Schnaier of the plumbing firm of Boyd & Schnaier, 347 Columbus avenue, New York, has been appointed one of the advisory board of the Baron de Hirsch Trade School. He will recommend a new system of instruction for the plumbing class that presents some excellent features. The course will require six months, and a month will be devoted to each of as many different branches of the trade, accompanied by special lectures. By this means the pupils of the school will all have received the same instruction at the end of the term, and like regular journeymen will have an opportunity to discover for which branch of the trade they are best qualified.

Norwood & Bayle is the name of the new firm in the plumbing, hot water and steam heating business at Pittsfield, Maine.

W. A. Putnam has purchased the tin and plumbing business of John R. Todd at Warren, Mass.

Spring & Prasse, Keokuk, Iowa, have opened up a plumbing, steam and hot water heating, tin and sheet iron shop at 418 Main street.

D. B. Sullivan, plumber and tinsmith, has leased the store, 57 Little Water and 49 Shetucket streets, Lucas Block, Norwich, Conn. He will move into his new quarters about May 1.

Campbell & Dunn will succeed the late firm of Carey & Campbell, plumbers, at Erie, Pa., the dissolution of which was brought about by the death of Mr. Carey.

Celete D. Lindsey has opened a plumbing shop at 16 Moore street, Bristol, Va.

John Tucker is sending out an attractively arranged circular, printed in brown ink, bearing the addresses 130 and 132 Bellevue avenue, Newport, R. I., and 253 Fourth avenue, New York. It is a notice of his recently opened branch establishment at the former address. Plumbing, gas fitting and hot water heating are solicited, and it is stated that a specialty will be made of yacht plumbing and fitting up Turkish, Russian, shower and needle baths. A list is given of prominent citizens for whom he has done work, as well as of architects and builders.

T. J. Tuomey, Seventy-second street and Third avenue, New York, is using one of the smoke testing machines made by the Bailey-Farrell Mfg. Company for testing plumbing systems. The smoke test possesses several advantages and he is well satisfied with his experience with it.

One of the latest attractions in the show windows of the plumbing establishment of T. Sullivan, 34 East Twentieth street, New York, is a gas engine such as is used by him in raising water to tanks of high buildings in which he erects the plumbing fixtures.

Roberts & Simmons is the name of a new plumbing firm on La Salle street, Aurora, Ill.

Hammon & Leddy have opened a plumbing, gas fitting and tin shop in the rear of 230 Main street, New Britain, Conn.

The Myers-Sniffen Company, Limited, 46-48 Cliff street, New York, are sending out a four-page circular devoted to the recently patented improvements of the Em Ess Doherty self-closing faucets. These faucets have been on the market for the past 17 years and have proven their quality. The new feature is in the shape of the lever which opens and closes the faucet. They are

now made in such a form as to prevent them from slipping quickly from the hand and the resulting shock from destroying the valve seat. The cuts show the different faucets that are found in plumbing systems and the text states that they are furnished in polished brass, nickel plated and silver plated.

J. H. Donnelly will move his plumbing and stove business into a new store on Main street, Springfield, Mass., May 1.

The E. Stebbins Mfg. Company, Springfield, Mass., have added a fine line of plumbers' specialties to the exhibit in the Board of Trade rooms.

A bill before the Massachusetts Legislature decides the question of what constitutes a practical plumber, so far as applying to the inspectors of plumbing throughout the State. It requires the Plumbing Inspector to have worked five years at the business.

Plumber J. H. Donnelly, Ware, Mass., will move May 1 into a new store in the Hampshire Block that has been remodeled and arranged to suit him. He will display an entirely new stock of goods.

The Master Plumbers' Association of Rhode Island held its annual convention last Tuesday afternoon in Foresters' Hall, Newport, about 60 members being present. Ald. James Openshaw, president of both the Newport and the State associations, presided, and National President D. G. Finnerty, Vice-President Tierney of Providence and Vice-President Deady of Worcester, Mass., were present as guests. The visitors were shown about the city by the local members of the body, and were entertained at a banquet, Joseph Haire and P. J. Murphy acting as toastmasters.

The John Douglas Company, Cincinnati, manufacturers of the Douglas tank, plumbers' wood work and sanitary closets, have opened a Chicago office in the Ogden Building, 34 Clark street, Room 511, with Geo. L. Bottum as manager. Samples of all goods manufactured by the company will be placed on exhibition. The warehouse at 80 to 82 Pratt street will be retained, and in it will be carried a full stock of goods. Mr. Bottum will also retain his connection with the Lausten Lead Works.

P. J. Murphy, the plumber, has fitted up a most handsome sample room at his establishment on Spring and Mill streets, Newport. R. I. A Mexican onyx wash stand is among the samples.

A press dispatch from Milwaukee, Wis., dated the 24th inst., states that the master plumbers and their men have reached an agreement and the danger of a strike is over, notwithstanding that the scale of wages is to be greatly changed. The new scale will go into effect on May 1. Heretofore there has been a sort of sliding scale, running all the way from $1, paid to boys, to $3.50, paid to skilled men. Now the men are divided into two classes and two rates are made, $2 for inferior men and $3 for superior men. That is, those are the standard wages for the grade. No inferior men will receive more than $2 per day and no superior men less than $3.

New Orleans, La., is to have a new system of sewers, on which the work has just been commenced.

Chicago Plumbers' Strike Ended.

We are in receipt of a dispatch from Chicago to the effect that the plumbers' strike has been settled through the efforts of the Arbitration Committee of the Master Plumbers' Association and the Journeymen's Association. The two organizations have made mutual concessions, but the most important feature of the settlement is that the journeymen are to receive the old scale of wages—namely, $3.75 per day of eight hours.

The Ette & Henger Mfg. Company,

St. Louis, Mo., have just issued their catalogue No. 5, devoted to plumbing and water works. The catalogue contains 175 pages and includes everything which this firm make under the title head of the catalogue. Especial attention is drawn to the following lines, which are said to be entirely new to the trade: Their National service boxes are referred to as meeting with considerable success. In this style box the rods are placed inside the box, the combination key is adapted for opening the covers and also to fit on the end of stationary rod, the same key serving both purposes. Their line of gate valves is particularly complete, and it is claimed by the manufacturers that they are unsurpassed for quality of material, workmanship and principle. Each valve is tested to 300 pounds pressure. The National compression stable hydrant on page 31 combines a hitching post and drinking fountain, and is guaranteed anti freezing. The merits of their Non-wasting hydrant are especially referred to. They call particular attention to their line of hose pipes, as shown on page 68. There are no joints, no packing, &c., in these pipes to leak or wear out, and they will throw a full stream or any spray desired. The spray adjustment will permit of a spray as fine as mist, and will close off pressure entirely, acting as a cock. Their pneumatic water works is a newly perfected and simple system for supplying water by means of compressed air to houses, hotels, schools, public buildings, stock farms, &c. Their line of combination bathtubs occupies ten pages in the catalogue and are referred to as portable self heating, and in addition will give singly or in combination any of the following baths—hot water, cold water, hot air, steam, dry or wet vapor, dry or wet electric foot baths, alternating hot or cold showers, alternating hot or cold and plain, perfumed, or medicated spray, douche, syringe or bidet baths, and in addition have an adjustable stool with comfortable lazy back, which by a simple arrangement will automatically rub the back, with either brush, sponge, towel, or electrode. In addition to the lines of goods above enumerated they show many other plumbing and water works devices, which will be appreciated by the trade. The catalogue is being sent to the trade, and those interested are requested to send for a copy, which will prove a valuable addition to trade literature in this line.

The Cataract Electric Company of Buffalo, N. Y., have closed a contract with the Niagara Falls Power Company, whereby power will be supplied for use in Buffalo about October 1.

FLASHINGS.

The Globe Ventilator Company, Troy, N. Y., are distributing to the trade an illustrated catalogue and pricelist in the interest of their well-known Globe ventilators and chimney caps. The pamphlet is tastefully published and many illustrations show the cap itself and its application to buildings. These goods are made in brass, copper and galvanized iron and are recommended for the ventilation of schools, churches, hospitals, theaters, halls, mills, factories, cars, stables and farm buildings of every character. They are also referred to as a cure of smoky and sluggish chimneys and a corrector of downward drafts. They are likewise useful in removing sewer gas and are employed for rendering attics comfortable. A description of the ventilators is given and many testimonial letters are presented from those who have used them.

The Decatur Steel Roofing & Corrugating Company of Decatur, Ill., are distributing interesting pamphlets descriptive of their specialties. One of these is an illustrated treatise on "Laying Steel Roofing," by L. S. Bonbrake, and the other shows the style of goods manufactured by the company, such as rock face brick siding, sheet steel pressed brick, beaded iron, crimped roofing, corrugated iron, steel clapboards, metal corner boards, crimped edge roofing, eave troughs, conductor pipe, elbows, &c.

Casey & Galligan are a new firm in the tinning, roofing and plumbing business on Iron street, Bloomingburg, Pa. Mr. Galligan was formerly employed by John Bird and J. S. Thorn of Philadelphia.

Work is being rapidly pushed on the tin mills at the Ætna Standard plant, Bridgeport, Ohio. The machinery has commenced to arrive and it is expected that operations will be commenced in from 60 to 90 days. The first mills built will be experimental, and if the venture proves successful several more will follow. The old puddling department of the Standard plant has been entirely cleared and the building will be used as a tinning house. This arrangement concentrates the tin plate operations, as the tin mills are being erected where the Ætna plate mill formerly stood, directly opposite the Standard puddling department. Many other improvements are going on at this already extensive plant, and an increase in the capacity of the galvanizing shop is under consideration. During the past few weeks the Ætna-Standard mills have been operated more steadily than at any time since work was resumed last fall.

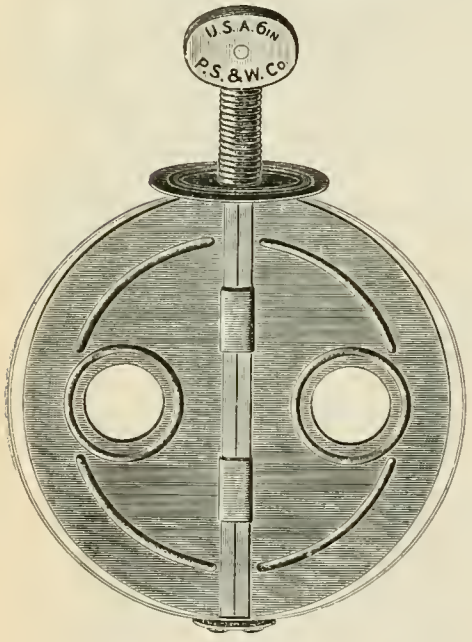
John Galt & Sons, dealers in slate, who for 21 years past have been located at 52 John street, moved to 253 Broadway, where they have fine new offices in Rooms 805 and 806 of the Postal Telegraph Building. This firm are well known in the slate trade, and are especially prominent in handling roofing slate of all kinds.

Baird, Thompson & Co. of Glasgow and London have recently fitted a new system of ventilation in several British steam vessels, which is said to be highly successful. Downcast and uptake shafts are fitted at either end of the hold to be ventilated, and ejectors, worked by compressed air, are fitted at the bottom of the uptake shafts. A constant circulation of air through the hold is thus secured.

THE RETAIL STORE.

U. S. A. Damper.

The Peck, Stow & Wilcox Company, 27 Chambers street, New York, are introducing the U. S. A. damper, as here shown. The disk is made of sheet steel with two 1 inch holes cut for escape of gas. The shaft is of wrought iron ¼ inch square bent double and pointed at the ends. On the side of the handle is a metal shield or disk to protect the double wood handle from heat. Between the handle and the shield is a tinned coil spring, put there to keep the damper rigid in any desired position. At the other end is a metal washer 1 inch in diameter, the pointed ends being spread or locked down with a chisel after the washer is in place. Holes ¼ inch in diameter are punched in the pipe on both sides. It is pointed out by the manufacturers that this damper is exceptionally light and that

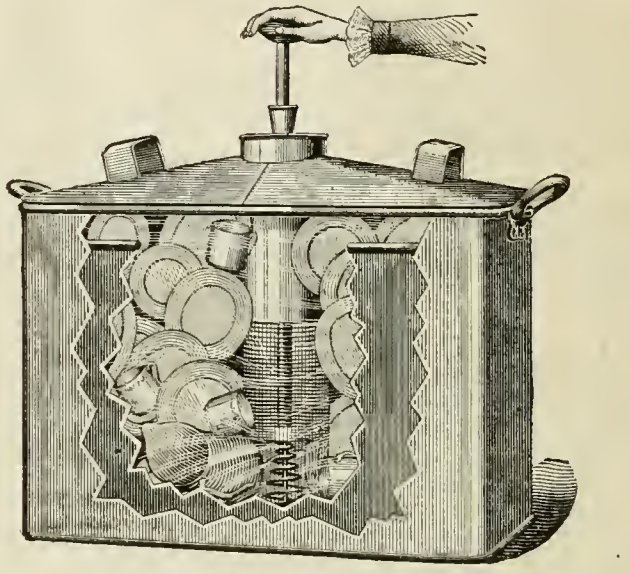


U. S. A. Sheet Metal Damper.

there is a proportionate saving in freight, and being of steel there is no loss from breakage, while the damper, if necessary, can with a pair of snip shears be cut to fit an oval, square or irregular size of pipe.

The Perfect Dish Washer.

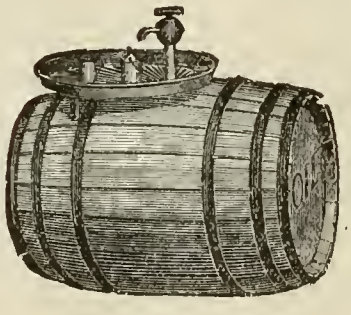
The illustration herewith shows the Perfect dish washer, which is just being put on the market by Geo. B. Cobb & Co., 96 Centre street, New York. It consists of an inner and an outer vessel with a cover. The outer vessel has a faucet at one end for emptying. The inner vessel has a perforated bottom and a perforated cylinder attached to it with a spring and a plunger within it. In operation the outer vessel is filled with boiling water into which soap or washing soda is dissolved. The dishes are packed in the outer vessel around the cylinder and then set in the water and the cover put on. The plunger is then moved up and down, forcing the water to rush over the surface of the dishes to dissolve and remove all grease, &c. When the dishes are washed the water is drawn off and a supply of clean hot water poured in to rinse them. The water is again drawn off and the inner vessel raised, and by means of handles with projections which catch on the top of the outer vessel the dishes are suspended to drain, and being hot they dry without the use of a towel and are said to have their natural polish. It is said that 50 dishes can be washed in five minutes without risk of breakage. The device is made of tin or galvanized iron in two sizes and is specially designed for household use.



The Perfect Dish Washer.

Barrel Pan for Oil Barrels.

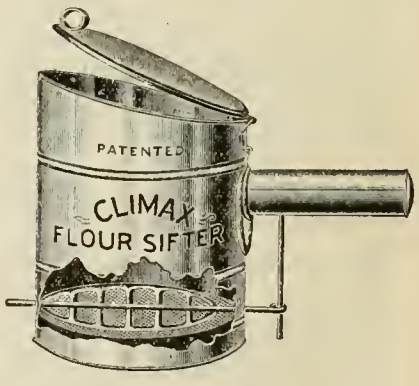
Sidney Shepard & Co. Buffalo, N. Y. are putting a barrel pan on the market, an illustration of it being given herewith. The apparatus consists of a pump, which is inserted in the barrel, and a pan surrounding it, the bottom of the pan being corrugated toward the pump aperture, thus draining all drippings of oil back into the barrel when used with illuminating or lubricating oils.



Barrel Pan for Oil Barrels.

The Climax Sifter.

We show in the accompanying cut a broken view of the Climax flour sifter, made by the Climax Mfg. Company, 415 Cuyahoga Building, Cleveland, Ohio. It is especially adapted to sift flour and is about 6½ inches high and 5 inches in diameter. The handle, it will be noticed, is so arranged that by a slight shaking motion the sifter is put into operation. It is worked entirely with one hand and by an easy motion.

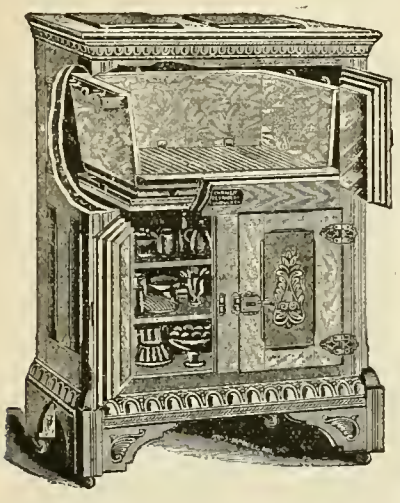


The Climax Sifter.

The Troy Nickel Works, Troy, N. Y., send out small cards illustrating and briefly describing the features of the Alaska tack hammer and of the Perfect ladies' tack hammer.

The Gurney Removable Ice Compartment.

The Gurney Refrigerator Company of Fond du Lac, Wis., have introduced a new feature in some of their refrigerators this season, in the form of a re-



The Gurney Removable Ice Compartment.

movable ice compartment, which is here with illustrated. It is used in that class of refrigerators in which the ice is put in through the front. It is supported by a heavy galvanized frame running around the back and two ends of the refrigerator, leaving ample air space for the air from the provision chamber to gain access to the ice. The compartment can be so readily removed for cleaning that the merits of this style of construction are obvious. The company have very recently been granted a patent on their application of this idea to a refrigerator.

Trilateral Pencils.

Joseph Dixon Crucible Company, 68 Reade street, New York, and Jersey City, N. J., have brought out a new form of lead pencil, as here illustrated, called the Trilateral. Its triangular shape prevents it from rolling off a desk, fits the fingers and does not tire the hand with constant use. It is handsomely finished, to resemble ebony, rosewood, satin wood and natural cedar, is full length and made in all grades from soft to hard. It is remarked that to those using a pencil continuously it will be found especially convenient.

Trilateral Lead Pencil.

Improved Coffee or Tea Urn.

Thomas Miller & Son, 106–108 Centre street, New York, are bringing out an improved Economy coffee or tea urn, as shown in Figs. 1 and 2. The main difference between this construction and the former is that the coffee or tea when made is kept hot and at a uniform temperature never reaching the boiling point, by means of a bath of hot air instead of hot water. Fig. 1 represents the urn complete, except the portable burner underneath. Fig. 2 is a sectional view of the apparatus. A is the cover, B the outer jacket, C a perforated metal spray pan for evenly distributing the boiled water, so that each portion of the pulverized tea or coffee is thoroughly saturated as the water passes through the mass. D is a cotton

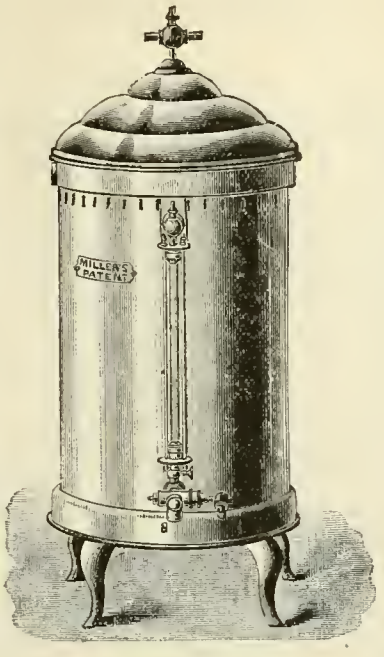


Fig. 1.—Economy Coffee or Tea Urn.

bag suspended from a wire rim, containing the tea or coffee. E is a stone crock receptacle for the tea or coffee, the enameling or glaze of which is guaranteed by the manufacturers not to craze. F is the hot air chamber between the jacket and crock, the supply of air entering at the bottom, and after being heated passes out through the perforations at the top, as seen in Fig.

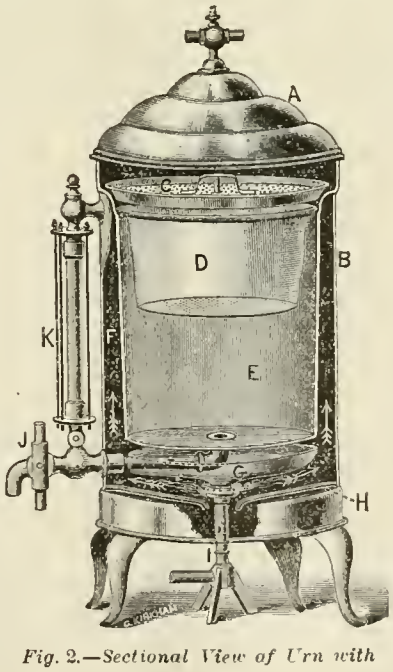

Fig. 2.—Sectional View of Urn with Burner Underneath.

1. By means of the cast iron diaphragm G, it is stated, the heat from the self-regulating gas burner I is radiated and evenly distributed, maintaining a constant bath or current of heated air against the crock E. The guard plate H is arranged to admit only a sufficient supply of air. I is an improved automatic self-regulating gas burner made for this service, although alcohol, oil, &c., can be used if gas is not available. J and K indicate the customary faucet and gauge glass. For a 4-gallon urn the manufacturers state the proper amount of heat costs but 2½ cents per day, with gas at $1.25 per thousand cubic feet. A glass eye piece at the bottom, 1⅛ inches in diameter, always affords a view of the burner. The urns are carried regularly in stock in capacities from 2 to 10 gallons, and larger sizes are made to order. They can also be furnished in sets of three with central water boiler and stone crock milk head with improved clean-out faucet.

MEMORANDA.

Yates & Co., Rockford, Ill., refer to their astringent lacquer as soluble, adhesive, tenacious and rust proof, and as proving a valuable acquisition to the stove dealer in making stove polish, rust proof varnish, rust proof roof paint, &c. The manufacturers state that upon application they will be pleased to mail to any dealer a pamphlet telling how to make a benzine paste stove polish at from 3 to 6 cents per pound that will prove a rust proof application and a durable jet black luster.

The Geuder & Paeschke Mfg. Company of Milwaukee, Wis., have issued a neat little pamphlet descriptive of the merits of their Cream City flour bin and sifter. The author of this publication has done his work in a most entertaining manner. Comparisons are made with the way in which "our mothers" used to get flour from a barrel, scraping against nails and spraining their backs burrowing in the barrel. The illustrations are effective, and in connection with the text show most happily the superior advantages of a flour bin and sifter over the ancient methods of handling flour in the kitchen.

C. Sidney Shepard & Co., 23 and 25 Randolph street, Chicago, have issued a spring circular of seasonable and other goods in their line as manufacturers of house furnishing goods in the sheet metal branch of trade. The circular covers 24 broad pages and gives illustrations and price-lists of water coolers, Lightning ice cream freezers, milk cans and can stock, creamery supplies, japanned bathtubs, cash boxes, dust pans, lamp stoves, family oil cans, tea and coffee pots, flue stoppers, flour sifters, egg poachers, mincing knives, conductor pipe, eave troughs, elbows of all patterns, sprinkling pots, gas stoves, tin plate, terne plate, mica, &c. The firm are manufacturers of a large line of deep and shallow stamped ware, pieced tinware and japanned goods.

March's failures in the United States were less than half, in number, compared with those of January last, while the proportion of capital involved was still smaller.

STOVE TRADE NOTES.

National Association of Stove Manufacturers.

In these columns last week we referred to the coming meeting of the National Association of Stove Manufacturers, and called attention to the plan which had been adopted with regard to papers to be presented at that time. As stated, the subjects to be covered were announced in our issue of March 31 in connection with the circular issued by Secretary Thomas. We now have pleasure in presenting below another announcement from the secretary's office, bearing date of April 21, and giving the names of the authors of some of the papers to be read before the National Association:

Allow me to remind you that the annual convention of the National Association of Stove Manufacturers will be held at the Auditorium Hotel, Chicago, on Wednesday, May 2, at 10 30 a.m., in accordance with my circular of March 24, also to repeat the cordial invitation to attend given by the president to all stove manufacturers, whether members or not. It is expected that papers of the greatest value and interest will be read and discussed. Among them will be an article on "A Theory of Ornamental Design as Applied to the Decoration of Stoves," kindly prepared by J. Leon Gobeille of Cleveland at the president's request; one on "Pattern Construction," prepared under the auspices of the Michigan Stove Company; one on "Foundry Management," by a gentleman now superintendent of one of our largest foundries, and whose competency is beyond question; two or more on "The Relations Between the Employer and the Employed," which will probably be written from different standpoints; one by Henry Cribben on "The Education of Apprentices and Maintenance of the Supply of Efficient Workmen;" one on "Cleaning Castings," by the good offices of the Abram Cox Stove Company; one on "Profit Sharing," by C. S. Prizer of Reading, whose paper last year met with such general commendation; one on "The Interchange of Information Among Stove Manufacturers," by the officers of the Fuller & Warren Company; one on "The Continental Stove Trade," by J. Goldschmidt, late United States Consul at Vienna, and others of general interest. It is hoped that there will be a full attendance of those gentlemen immediately connected with the productive department, as the meeting is expected to be of special interest to them, while there will be no neglect of topics connected with the distribution of goods.

W. H. Switzer, secretary and general manager of the Superior Furnace Company of Little Falls, N. Y., has recently returned from an extended business trip throughout the Western States, where he called upon the many patrons of the company, all of whom speak in glowing terms of the excellent results achieved in the past from the sales of this popular line of furnaces and heaters. We are advised that the prospects bid fair for a large increase of sales for the season of '94, judging from the many new agencies established by Mr. Switzer and the booking of some large orders for early shipment.

Electric Heating and Cooking Apparatus.

The likelihood that a vigorous effort will be made to utilize electricity for heating and cooking apparatus has induced the New York Board of Fire Underwriters to adopt the following special rules:

Electric Heaters, Ranges and Stoves.

a. These must be placed in safe situations (out of easy reach of inflammable materials) and separated from and supported on non-conducting and incombustible standards or bases so as to be at least 4 inches from wood work of any description or other inflammable material, unless protected by non-combustible materials, such as sheet metal and asbestos, or the like, so combined as to prevent appreciable transmission of heat, while securing full insulation. The heating wires or resistances of these heaters, &c., must be inclosed in non-combustible cases adapted to prevent accidental contact with exterior object or material.

These electric heaters, stoves, &c., must never be concealed, but must be at all times in plain sight.

b. They must have double pole switches, cut outs, &c, arranged as required for electric lights or power apparatus employing the same current and potential.

c. The attachments of feed wires to heaters, &c., must be in plain sight, easily accessible and protected from interference, accidental or otherwise.

d. Attachment of conductors to heaters, &c., must be securely made in the same manner that conductors are attached to motors or generators dealing with currents equal to those employed in these devices, and such conductors must be continuous from the heaters, &c., to the switch or cut out, which must not be within 2 feet of said heaters, &c. These conductors must be thoroughly well insulated and also covered with a good mechanical protection.

Portable Cooking Apparatus, Glue Pots, Curling Irons, &c.

a. The heating coils or resistances of these instruments must be inclosed in non-combustible cases, which in turn must be mounted on non-conducting and incombustible bases raising the same at least 1 inch from any surface on which they stand.

b. These instruments must not be attached to lamp sockets, and when current of more than 10 ampères is required they must conform to the same rules as heaters, ranges, &c.

c. Where currents of 10 ampères or less are required these instruments may be connected by specifically approved flexible double or twin wire conductors, provided such conductor is composed of two multistrand conductors, each of which is insulated by a water proof material and asbestos, while both are surrounded by a covering affording adequate mechanical protection. These flexible cords must also be connected to plug switches having double pole fuses in their sockets which will cut out the circuits if a cross connection should occur in the flexible conductor. Moreover, such plug switch must be so arranged that the plug will pull out and break the connection if an abnormal mechanical strain is brought on the flexible conductor.

The leading in wires of these flexible cords must be connected to heaters or the like at the point of lowest temperature, and where such wires are detachable at the heater, their terminals must be arranged with female ends protected by porcelain extending at least ⅛ inch beyond the metal terminals.

If the connection at the heater is fixed, a separable double pole connector must be placed in the circuit, so that in case an undue strain is brought on the conductors the device will be automatically cut out and disconnected.

Flexible cord connections longer than 6 feet will not be permitted.

Receptacles for plug attachments must be placed at least 6 inches above the floor.

Where switches are provided they must conform to the rules laid down in Section 26 of the General Requirements.

Where a number of utensils are grouped for general cooking service, installations to be approved must be provided with slate, soapstone or other approved slab or table for utensils to rest upon. Plug receptacles mounted on slate or other approved material shall be attached to mains running at least 6 inches above the working service of the table.

Sad irons and other heating appliances that are intended to be applied to inflammable articles, such as clothing, must be arranged as above as far as connections, &c., are concerned, and must also be provided with approved attachments which will cut off current when they are not in actual use.

The leading in wires to these forms of apparatus must be connected through porcelain connecting blocks, and the cable or cord of the same must be passed through an insulated elastic spiral or spring so arranged as to protect the same from kinking, chafing or like injury at or near the point of connection.

These conductors must be so placed that they will at all times be at least 4 feet from the floor and well protected against contact with water pipes or other possible ground connections.

The use of no flexible cord will be permitted, unless specifically approved by this board.

Gas for Fuel.

At the tenth annual meeting of the Ohio Gas Light Association, held at Columbus, Ohio, March 21–22, a paper by Donald McDonald on the subject of gas for fuel was presented. In his opening remarks the author enumerated some of the forces working from different directions tending toward the increased use of gas as a fuel, and also referred to a few of the forces which are retarding it. Among the latter he states that one is the attempt to use gas for purposes where its cost and other properties make its failure a foregone conclusion. "For cooking or for occasional fires," he says, "gas can be used with economy at $1 a thousand, but the man who attempts to heat a bedroom or an office with it at that price will certainly become disgusted with the whole business, and will very properly blame the gas company that induced him or allowed him to waste his money on such an experiment. With a good gas at 50 cents a thousand, all sorts of cooking can be done with it, and the heating of parlors and dining rooms, and those bedrooms which are not used as sitting rooms during the day, can be done at a cost so little greater than the cost of coal that people will put up with it on account of the greater convenience of gas. At 35 cents a thousand for a good gas containing, say, 700 heat units, gas can be used as a heating agent all over a residence, and the cost will not exceed

that of anthracite coal at $8 a ton or soft coal at $3.50 a ton, after allowance is made for kindling and labor. . . . If gas at 50 cents a thousand is burned in a good gas stove in a tolerably close room without any chimney draft, the products of combustion escaping into the room, the amount of gas required to heat the room will be so small that coal will not compete with it in price. The room, however, if it is small and close, will become unfit for habitation, owing to the consumption of the oxygen of the air and the formation of carbonic acid and watery vapor. . . .

"A room 16 x 16 x 12 contains about 3000 cubic feet, and will require 2177 heat units in order to bring its temperature up from 30° to 70°. If the combustion is perfect, and there was no other loss than that due to the actual products of combustion escaping at 300° F., such a room should be heated from 30° up to 70° with a consumption of 3 feet of gas per hour; or assuming that the air is changed three times per hour, and that there is no loss through the walls or windows, 9 feet of gas per hour would keep such a room warm.

"I was so much surprised at this low figure that I constructed a gas stove on this principle. It was of sheet iron, so made that no air could enter it except what was necessary for combustion, and this air was compelled to enter it at the very point where the flame originated. This I accomplished by using the ordinary burner composed of a piece of ¾-inch gas pipe, with holes ⅛ inch in diameter drilled 1 inch from centers and fitted on the end with an ordinary mixer and stop cock, so arranged as to take in air and gas mixed, and provided with valves so that the amount of air and the amount of gas taken in were capable of absolute adjustment. This burner was placed inside of a 2½-inch pipe of the same length, with holes ⅝ inch diameter, in such a way that the jets of mixed air and gas issuing from the small pipe were projected through holes in the larger pipe, and, of course, met a supply of perfectly pure fresh air, drawn in from the outside. The stove was connected to the chimney by means of a 4-inch flue pipe and there existed at all times a vacuum in the stove, so that whatever leaks accidentally existed in it served to take in air, but never to permit the escape of the products of combustion.

"I found that with this stove I could maintain the temperature of a room 16 x 16 feet with a 12-foot ceiling at 68° while the thermometer outside varied from 25° up to 35°, the consumption of gas being only 13 feet per hour; and the room being at all times sweet and wholesome.

"I drew some air out of the interior of this stove and analyzed it, and found that its composition was as follows: Carbonic acid, 6½ per cent.; oxygen, 7 per cent.; and the remainder was, I presume, nitrogen. Of course, such an atmosphere as this would be absolutely fatal to any kind of life in a little while. A lighted candle placed inside of the stove goes out in a few minutes, and even a stream of gas poured in against the flames refuses to light, for lack of oxygen with which to burn.

"Now, let us assume that instead of allowing these products of combustion to escape up the chimney, we allow them to escape into the room; the result would be that at the end of the hour the room would contain 13 feet of carbonic acid and a considerable quantity of watery vapor and would have its supply of oxygen depleted by about 26 feet. Thus we have in one hour lowered the oxygen to 19 per cent. and raised the proportion of carbonic acid from four parts in 10,000, at which it originally was, to 48 parts in 10,000, which is a great deal more than any of the authorities on ventilation allow and which does as a matter of fact render the room in question exceedingly oppressive.

"Of course the amount of gas required to heat the room by this last method is somewhat less, but the difference is evidently not worth the cost at which it is obtained.

"In pursuing this inquiry, I have examined the cuts of all the gas burning appliances which I could obtain; and in none of them do I find any attempt to separate the products of combustion from the surplus warm air before they reach the chimney. They all go on one or two theories; the first is to carry nothing up the chimney and allow everything to escape into the air of the room. This may be described as very cheap and very nasty. The other plan is to provide ample chimney draft, and let the householder pay the bill. This is healthy enough, but it is very expensive.

"I feel certain that gas will eventually take its place as the principal heating and cooking agent of the people. Before it can do so, however, the managers of gas companies must be prepared not only to make a good gas and sell it cheap, but also to instruct their patrons how to burn it so as to secure economy in the cost and a wholesome atmosphere in their houses. As long as the public have to choose between extravagant gas bills and close, oppressive rooms, the progress of gas for heating will be slow."

The Chicago Stove Trade.

If a report on the condition of the Chicago stove trade should be based entirely on what one or two manufacturers say, it would be very short. In reply to questions about trade they reply laconically, "There is none." Of course, they do not mean to be taken literally. They have not closed their foundries, called in all their traveling men, and made arrangements for going into liquidation. Their shipping departments are still fully manned and their order books pass no dates but Sunday. Their teams may haul occasional loads of flour or salt or miscellaneous merchandise, to earn an honest penny outside, but they have not entirely ceased to haul stoves. The expression referred to is simply used to emphasize the dullness prevailing. There is a stove trade in Chicago at the present time, but it is not up to what it should be. The influences which have dominated all kinds of business for the past twelve months are still in full force and effect, and the stove trade is obliged to suffer with every other branch of trade.

So far as the demand for stoves has existed its character has not differed radically from that of previous springs. Cook stoves and ranges have constituted the bulk of the business in staple goods. Advance orders have been taken for some heating stoves to be delivered in the early fall, but not to any great extent. The orders for cooking goods have been much smaller than in other years. Merchants will not anticipate their requirements, and regard the purchase of six stoves of six different patterns as a large order. In most cases, in fact, merchants are not ordering stoves until they are absolutely certain that they can sell them. This bareness of stocks, however, often brings about an accumulation of orders in the manufacturers' shipping departments which for a brief time restores at least a semblance of activity. The city trade this spring has been much smaller than that originating in rural districts. This is partly due to the hard times, which are felt most severely in cities, but is also ascribed to the large numbers of second hand cooking stoves thrown on the market shortly after the World's Fair by temporary sojourners in Chicago who had engaged in housekeeping during their stay. The number of these birds of passage was much larger than would have been supposed.

Some peculiar features of current trade may be especially noted. While a certain demand exists, and always will exist, for the highest priced stoves and ranges, yet the reduction of incomes and lowering of wages have caused a general turning to medium priced goods. This movement is recognized by manufacturers and is to some extent encouraged by them. Their medium priced goods are now of a much higher grade than ever before and they substantially offer a first class article for the lower rate. This is seen in steel ranges as well as in cast goods. The very best grades are held at high prices because manufacturers claim that they cannot be made to sell at any reduction, but they are offering very fine ranges, which they term medium priced goods, at much more reasonable rates, and find that these are reaching the people. Another feature of recent trade is that successful trips are reported by salesmen who have canvassed the very small towns which are usually neglected in ordinary times. Residents of such towns, being more closely identified with agricultural interests than in larger towns possessing manufacturing establishments, do not feel the depression in trade so seriously and are not economizing so rigorously. Notwithstanding the demagogic cry that farmers are in a chronic state of poverty, perpetually ground in the dust by the "money power," the farming communities of the West are found to be in much better shape than manufacturing communities. They may not enjoy all the sweets of prosperity occasionally tasted by manufacturers, but, on the other hand, they are not obliged, as now, to drain to the dregs the bitter cup of adversity.

The Kernan Furnace Company, formerly 59 Wabash avenue, Chicago, have moved their office to 71 and 73 West Washington street. The com-

pany will discontinue the retail branch of their trade, which will be in charge of W. J. McKay & Co., at the above location.

ODD PLATES.

The Prince Royal hot air furnace, made by Hart & Crouse, Utica, N. Y., is placed at the front of the New York showroom, at 211 Water street, by Manager W. M. Mackay. It is popular on account of being very low, giving a good pitch to hot air pipes, and having three No. 14 steel radiators it has a good heating capacity. Another feature is, the central dome being very large, excellent service is secured by the water heating coil when it is used as a combination heater.

W. Lapp & Co., 8 Peck slip, New York, make a specialty of sheet iron goods. They manufacture oyster ranges, broilers, pastry ovens, confectioners' and tinners' furnaces, as well as a line of coffee urns and broilers.

The Chicago & Erie Stove Company of Erie, Pa., have issued a circular showing the popularity with the trade of the Helper steel range, which they manufacture. The circular bears a letter from a customer in Parish, N. Y., in which he tells of the success in the way of sales resulting from a personal visit to the people in that section of the country and a demonstration of the merits of the stove named. The customer took the ranges in his wagon, and driving through the country showed the people how they would bake in the open air in the coldest weather and disposed of large numbers. By peddling out the stoves in this way the customer states that he has them favorably introduced and is certain of building up an extensive trade.

The Fuller-Warren Company of Milwaukee and Chicago favor us with copies of three pamphlets relating to warm air furnaces. One of the publications is devoted exclusively to wood burning furnaces made both horizontal and vertical, and another relates to the company's top return flue furnace adapted for hard or soft coal. This heater is made with cast radiator and is offered in portable form and also arranged for brick work. The third pamphlet relates to the same general line and presents in addition the details of construction. These goods are offered in a great variety of styles and sizes suitable for warming buildings of all kinds. The company have had more than 50 years' experience as heating and ventilating engineers, and are thoroughly familiar with the requirements of the public in this respect.

The Perry Stove Company of Albany, N. Y., have issued a convenient pamphlet telling of various kinds of oil and lamp stoves, among the number being two new constructions. One is the Royal F, an oil stove with four 4-inch burners, permanent extension top with four cooking holes and loose divisions, front and back. The body of the stove is of cast iron, nickel plated. The other new feature is a Royal lamp stove with two 4-inch burners, and is highly finished in nickel and japan. It also has the company's special burner, which is oil tight, and Russia iron chimneys with removable mica.

The Lehigh Stove & Mfg. Company of Lehighton, Pa., are favoring their friends in the trade with blotting pads of a size which renders them convenient for desk use. The paper is of yellowish tinge and carries printed matter in red. The inscription is to the effect that "Lehigh stoves and ranges are made only by the Lehigh Stove & Mfg. Company of Lehighton, Pa."

The Davis, Johnson Company have opened an agency for the sale of Schill's New Idea furnace at 45 East Jackson street, Chicago. The New Idea furnace is manufactured by Schill Brothers, at Crestline, Ohio, and is adapted to the use of hard and soft coal, coke, wood and gas. This furnace has been on the market but a short time, yet the manufacturers have already built up a large trade for it. They have added some improvements for 1894 which they are confident will win for it still greater favor.

The Thatcher Furnace Company have issued an announcement under date of April 23, to the effect that on account of increased business they will remove May 1 to 240 Water street. This location is central, and with the more commodious quarters which they will occupy gives the company much better facilities for exhibiting their line of goods and for carrying a larger stock than heretofore.

The Chicago & Erie Stove Company of Erie, Pa., send us a copy of a circular which they are about mailing to the trade relative to the Gas Helper range. The top surface of the range is provided with four burners having central draft and sawed on the side so they are not liable to fill up. It is also claimed for these burners that they are very economical, because they spread the flame into thin sheets, thus securing a large amount of heat in proportion to the quantity of fuel used. The two burners under the oven are easily lighted from the side by an ingenious device. The oven is made of light iron so that it will heat quickly and is mounted on a cast iron frame that fits to the front and can be drawn out as a drawer from a bureau, by lifting out two rivets at the bottom front.

The Baxter Stove Company of Mansfield, Ohio, have issued, under recent date, an announcement to the effect that, having just completed the adjustment of the losses sustained by the fire which visited their works on April 5, they are now prepared to close out their stock of Baxter's Banner stoves which were stored in the warehouse at the time of the fire, and which were somewhat damaged thereby. These stoves, we understand, were not subjected to the direct action of the fire, but were only damaged by water. They were promptly dried off and all nickel work replated, so that they can be cleaned and blackened with but little labor and retailed at prices fully as good as new stoves. With the circular letter the company are sending a list of the damaged goods which they will sell, subject to prompt reply, at specified discounts from list prices.

E. L. Tallmadge, formerly with Janes & Kirtland, has connected himself with the house of Eugene Munsell & Co., 218 Water street, New York, where he will act in the capacity of shipping clerk. He is well equipped for this service, as he is equally skillful in marking with either hand, which is a gift by no means common.

The Superior Furnace Company of Little Falls, N. Y., inform us that after May 1 all shipments of Superior furnaces, heaters and ranges to the Western trade will be made directly from their works, thus dispensing with the expense attending the carrying of a stock in Chicago for reshipment. In view of this fact all orders and communications should be directed to the company at Little Falls, N. Y., where they will be given prompt attention.

The Boynton Furnace Company, 195 and 197 Lake street, Chicago, have issued an important circular to the local trade, under date of April 20. In it they say that in addition to their large wholesale trade throughout the country they have been doing construction work in Chicago and suburbs for over eight years. During that time they have put in thousands of heaters and gained a high reputation. They continue: "We have decided to try a new departure—to discontinue construction work and, so far as possible, distribute this part of the business through the retail trade. We shall continue to advertise the goods as heretofore, and have a sufficient corps of competent salesmen who will canvass the city and suburbs, interesting parties so far as possible using our heaters and ranges, and we desire the co-operation of the local dealers who may feel interested in this new departure. If we can secure sufficient encouragement as manufacturers and wholesalers that the sales of our goods will not be lessened, this plan of operation will be permanent. It will cost us something to make this experiment, but we venture it with a hope that it will be a success for the retail trade as well as ourselves."

The Central Electrical Heating Company, 26 Cortlandt street, New York, are installing a complete electrical kitchen in the United States receiving ship "Vermont," at the Brooklyn Navy Yard.

Duparquet, Huot & Moneuse Company, 43-45 Wooster street, New York, manufacturers of French ranges and hotel and restaurant cooking apparatus and utensils, are engaged in fitting up the kitchen for the Hardware Club in the Postal Telegraph Building. They also fitted up the kitchens of the Metropolitan Club, at Sixtieth street and Fifth avenue, the Girard Hotel, Forty-fourth street and Broadway, and the Arkwright Club, at Broadway and Duane street. The culinary department of the Insurance Club, in the Mutual Reserve Building, was equipped by them.

The Smith & Anthony Company of 48-54 Union street, Boston, Mass., have taken the agency for the Splendid oil cook stoves, the special features of which consist of steel bodies and tops and brass burners and tanks. Outwardly these goods have much the appearance of gasoline stoves, which they are intended to replace. The burners are very powerful, one of them having a 15-inch wick. The Smith & Anthony Company control this line of stoves in the New England States and are in a position to promptly handle all orders with which they may be intrusted.

C. B. Baker, 52-54 High street, Cleveland, Ohio, recently issued an announcement to the effect that on April 5 the partnership heretofore existing between him and W. S. Myers was dissolved by mutual consent. The business will be continued at the place named by Mr. Baker.

The recently appointed postmaster of Corning, N. Y., is George W. Drake of the Corning Stove Company of that place. Mr. Drake is probably one of the youngest postmasters in the country, he having been born Novem-

ber 10, 1870, in the little town of Arnot, Pa. From a brief sketch of his life presented in one of the local papers, we learn that after spending his childhood days among the miners he moved with his parents to Corning. He was educated in the Corning Free Academy and in Holbrook's Military Academy, at Sing Sing, from which institution he graduated. Soon after he was engaged in his grandfather's bank, holding the position until three years ago, when he became identified with the Corning Stove Company. Mr. Drake's likeness appeared recently in the "Elmira *Telegram's* Picture Gallery of Prominent People."

Rathbone, Sard & Co exhibit on the sample floor of their Chicago house a specimen of their new steel Acorn range. This is a very handsomely finished but moderate priced steel range. It is furnished with high closet or high shelf, bracket reservoir or water front. The fire pot has double draft, both in front and at the side, so as to secure perfect combustion. It is fitted with a duplex grate, and the deep ash pan is made of planished steel. Special care has been taken in the trimmings. The edges of the high shelf are nickel plated and not merely polished. Nickeled pilasters of ornamental design cover the front corners, and a cornice extends along the bottom, which is usually left square and unrelieved. Very heavy nickel bands extend round the several doors. The high closet has a canopy top. In the high shelf there is a panel on each side of the pipe which forms a convenient tea pot shelf. These panels are hung on pivots near the bottom, so that the top swings over when needed for a shelf. The bottom is weighted, and the shelf swings up again when relieved of its burden. The oven door is so made that it can be held open ¼ inch so as to ventilate the oven or cool it off. The walls are lined with asbestos, which is covered with an iron grating so that it cannot be torn off. Six sizes are made, but the fire chamber fixtures are interchangeable in all, thus permitting a smaller stock of repairs to be carried, which is a feature that will be appreciated by dealers. This range is made with 18, 20 and 22 inch ovens and with four and six cooking holes. The line is thus complete in every respect.

The Peninsular Stove Company are bringing out a new heater, to be known as the Air Tight Peninsular. It is an incased stove with interior construction after the style of an oak stove. The exterior work will be very ornamental, so that the stove will be fitted for use in richly furnished rooms. It will be made in three sizes to suit all requirements.

Edmond Raftery, assistant manager of the Chicago branch of Rathbone, Sard & Co., sails for England on May 5, for a two months' visit to relatives.

The Peninsular Stove Company of Detroit, Mich., have just completed and placed upon the market a new soft coal heater which is known as the Air Tight Peninsular. It is offered in three sizes, at a low price, and is ornamented in an effective style. The outer cast section is open fretwork, connected with openings in the extreme bottom, thus allowing for a free circulation of air and forming a complete double heater. The stove, as its name implies, is air tight, having few joints and these carefully fitted. The inner body is made of No. 12 cold rolled wrought steel, thus insuring, it is claimed, quick and powerful radiation, and at the top of the body of the heater is a heavy globe dome so arranged as to conduce to perfect combustion.

The Union Stove Lining Company of Weir Village, Mass., recently closed their plant owing to business depression, but it is intimated that the works will resume as soon as the situation improves. The company have been working full time right along, and when they resume operations they hope to be able to continue with a full force.

A. T. Matthews, general manager of the Matthews Mfg. Company, Worcester, Mass., makers of steam pipe collars, ferrules, stove trimmings and seamless sheet metal specialties, has returned to Worcester after a very enjoyable Western trip, during which business and pleasure were combined in about equal parts.

The Enterprise Stove Works, at Vincennes, Ind., shut down for a few days, a week or two since, in order to make some necessary repairs.

The Carmichael-Wilks Range Company of Chicago have recently been incorporated, with a capital stock of $50,000. The incorporators include D. L. Carmichael, W. B. McCloud and Perry Russell.

The Indianapolis Stove Company of Indianapolis, Ind., are now running full time with a force of 100 men. President Bennett states that there is no rush of orders, but enough are received from time to time to keep the works running with the force named.

The Carton Furnace Company of Utica, N. Y., have brought out a new heater known as the Carton hot blast smoke burning furnace, with vertical combustion flues. It is made of cast iron without the use of bolts and is claimed to operate without soot, dust or gas. The manufacturers state that the furnace has been thoroughly tested and every heater is guaranteed.

The Bellaire Stove Works of Bellaire, Ohio, which have been closed for several months, resumed operations last week with a force of about 200 men. We understand that the company have a fair amount of business on their order books and expect to run regularly until July 1.

The Fuller & Warren Company of Troy, N. Y., have nearly ready for mailing to their friends in the trade circulars of two new ranges. One of these is a double oven range made in portable form and also adapted for brick work, while the other is a single oven range bearing the name Stewart. The latter has a large square oven and is also provided with the company's patent oval fire box with their triple interchangeable grates — namely, the Dockash, triangular and draw center. In fact, the manufacturers state that all their ranges are now made with these three grates. We also understand that the company have just completed a basket grate for wood which can be used in any of their fire boxes.

Schill Brothers of Crestline, Ohio, have brought out a pamphlet for 1894 containing a long list of testimonial letters from some of those who have used their furnaces. The last page of the pamphlet illustrates and describes a recent addition to their assortment which is being offered under the name of the Schill furnace. This is said to contain all the fuel saving and heat producing qualities that have made the New Idea so well known, and has patent center draft, diving flue, double fire pot, shaking and drop center grate, asbestos packed joints, cast front and heavy castings. The dimensions are the same as the New Idea except the drum, which is 26, 30, 36 and 40 inches in diameter in the various sizes.

The Art Stove Company of Detroit, Mich., favor us with copies of two catalogues neatly bound in colored paper covers which they have issued to the trade. One relates to the Laurel steel range, which is made with the modern features and is offered in a great variety of styles and sizes. This range, we understand, has proven very popular, and can be furnished with a water front or hot water reservoir, as may be preferred. The second pamphlet illustrates and describes the Laurel oil heaters, which embrace sheet iron drum constructions as well as lamp stoves. Among the assortment is a combination heater arranged with a top cooking surface, provided with two boiler holes. The construction is termed a parlor cook stove, and being mounted on rollers can be easily moved from room to room. The manufacturers say that these goods are meeting with gratifying success, and that among other places they have been used by the pupils of the Chicago Cooking School. A few pages are devoted to the Laurel ovens, drums for the Art Laurel stove, cooking tops and Laurel wicks.

The Quick Meal Stove Company, St. Louis, report an excellent trade for the Quick Meal gas and gasoline stoves. A recent letter from a customer in Louisville, Ky., contained the following: "Notwithstanding the hard times we are meeting with splendid success with the Quick Meal stoves, and think we will sell as many, if not more than we did last year." Their traveling men are sending in encouraging reports, and all things considered, they are well satisfied with the outlook.

OBITUARY.

ALFRED HOPKINS.

Alfred Hopkins of Bridgeport, Conn., well known to the plumbers of his own State and to those who have visited the different National conventions, died at his home very suddenly last Wednesday afternoon from rheumatism of the heart. For more than 40 years he has been engaged in the plumbing and stove business on Water street, Bridgeport. He was 62 years of age, and is survived by a widow, a son, William P., and a daughter, Mrs. L. E. Sage.

W. H. Hill's stove and tinware store, at Marlboro', Mass., was badly damaged by a fire which visited the Burke Block in that city on April 26.

There is a probability that the pottery troubles which have agitated Trenton, N. J., for so long may be settled by an agreement between the manufacturers and the men before the end of the present week. About 4000 operatives have been locked out in that center of the pottery trade since last January.

The umbrella trust is reported to be in a state of disintegration. The combination was formed about two years ago with a nominal capital of $8,000,000, and included most of the leading manufacturers. It is not, however, proving remunerative, and has not served to quell competition.

TRADE REPORT.

The Iron Market.

The market shows an improving tendency, and while prices are about the same it is easier to do business than it has been for a long time past. Consumers' requirements are widening, and in many cases deliveries are called for with the utmost urgency, showing that stocks are low, and that whatever demand there is must be supplied from new purchases. The amount of business done during the past two weeks is larger than for any similar period since last summer, and while there may be somewhat of a pause during the remainder of the month, there is good reason for believing that the improvement is genuine and likely to be maintained for some time to come.

The labor troubles are the principal element of uncertainty in the situation at the present writing. The general strike of the Bituminous Coal miners and that of a portion of the Connellsville Coke workers may, if lengthened out, seriously affect some of the mills and furnaces.

The strike in Alabama would influence quite different interests if established and continued. It would touch the founders throughout the country. As yet all the furnaces in the Birmingham district are running and the chances seem to be against the men, many of whom recognize that since there has been no change in wages in the last five years, in spite of the enormous shrinkage in the price of Pig Iron, a reduction is a necessity.

One of the interesting transactions of the past week has been the closing of an 85-mile Wrought Iron Pipe contract for the natural gas belt at Lafayette, Ind. A works on the Delaware River has captured the lion's share of the order, from 50 to 55 miles, while the balance is taken by Pittsburgh. Eastern Pennsylvania mills are to furnish the material for that part of the order which goes to their section.

Pig Iron.—The event of the week, so far as the New York market is concerned, is the announcement that the rate on Pig Iron from Birmingham to New York, rail and water, has been reduced to $3.50, a cut of 50¢ a ton. It is not surprising in the present condition of affairs that sellers are promptly giving away this reduction to buyers. As yet sellers of Alabama Iron in this market do not seem to have received any positive instructions to withdraw. It is reported that Buffalo furnaces have swept the Canadian market, making large sales of that Iron, with some Southern brands for mixing with it. We quote standard brands $12.50 @ $13.25 for No. 1; $11.25 @ $12 for No. 2, at tidewater. Southern Iron, same delivery, $11.50 @ $12.25 for No. 1; $10.50 @ $11 for No. 2; $10 @ $10.25 for No. 3; $10.25 @ $10.75 for No. 2 Soft, and $10.50 @ $11 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $9 75 @ $10.25.

The demand for Pig Iron in the Philadelphia market has been very satisfactory, and while prices are in some cases the lowest, there is nevertheless a better feeling. In standard Foundry Irons there is a steady run of orders, and furnaces are in better shape than they have been for some time. There is a little irregularity in prices, due to the difference in freights to certain points, but on the whole the situation shows improvement, mainly in the better demand, which, however, is a necessary preliminary to better prices. General quotations for Philadelphia or equivalent points are about as follows:

Standard No. 1 Foundry X	$12.50 @ $11.85
Standard No. 2 Foundry X	11.75 @ 12.25
No. 2 Plain	10.75 @ 11.00
No. 1 Soft	11.50 @ 12.00
No. 2 Soft	10.75 @ 11.00

In Chicago the trade in local Coke Irons has latterly been confined to carload orders almost entirely, but they have been fairly numerous. Advices received from the Southern furnace companies state that they are very much disturbed over the strike among the Coal miners. Consumers, however, are not buying much Southern Iron at present, so that the strike in the South will hardly cause much annoyance in this section. Prices thus far have not been affected. The greater part of the trade now occurring is with country customers, as the city foundry trade has been decidedly curtailed by the local building troubles. Lake Superior Charcoal continues very quiet. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @ $15.50
Local Coke Foundry, No. 1	11.25 @ 11.50
Local Coke Foundry, No. 2	10.50 @ 11.00
Local Coke Foundry, No. 3	10.00 @ 10.50
Local Scotch	11.50 @ 11.75
Ohio Strong Softeners No. 1	12.50 @ 13.50
Southern Silvery, No. 1	..... @ 11.50
Southern Silvery, No. 2	..... @ 11.00
Southern Coke, No. 2	10.00 @ 10.35
Southern Coke, No. 3	9.75 @ 10.00
Southern, No. 1, Soft	10.25 @ 10.50
Southern, No. 2, Soft	9.75 @ 10.00
Tennessee Charcoal, No. 1	15.00 @ 15.50
Tennessee Charcoal, No. 2	14.50 @ 15.00
Alabama Car Wheel	17.85 @ 18.00
Jackson County Silvery	15.00 @ 16.00
Other Ohio Silvery	12.50 @ 13.00

The Coke strike is the disturbing influence in the Pittsburgh district, and will probably cause an advance in the market prices of Pig Iron. Foundry Irons are in very light demand, the foundries, as a rule, not being employed to more than half capacity. A sale is noted of fifty tons No. 2 Foundry at a price equal to $10.25, Pittsburgh. Quotations are given as follows:

No. 1 Foundry	$11.00 @ $11.25,	cash.
No. 2 Foundry	10.25 @ 10.50	"
No. 3 Foundry	9.75 @ 10.00	"

There has been little or no business in Pig Iron in Southern markets during the week, for the furnaces were not disposed to take orders for fear they might not be able to obtain Coal for an indefinite time, although they do not look for a prolonged contest. On the other hand, consumers of Iron do not require immediate supplies and are getting enough on contracts for their current necessities. Quotations are merely nominal, as follows:

Southern Coke, No. 1	$10.25 @ $10.50
Southern Coke, No. 2	9.25 @ 9.50
Southern Coke, No. 3	8.75 @ 9.00
Ohio Soft Stone Coal, No. 1	14.50 @ 15.50
Ohio Soft Stone Coal, No. 2	14.00 @ 14.50
Lake Superior Coke, No. 1	12.50 @ 13.00
Lake Superior Coke, No. 2	11.50 @ 12.00
Hanging Rock Charcoal, No. 1	17.00 @ 17.50
Hanging Rock Charcoal, No. 2	16.50 @ 17.00
Tennessee Charcoal, No. 1	13.00 @ 13.50
Tennessee Charcoal, No. 2	12.00 @ 12 50
Standard Southern Car Wheel	16.25 @ 17.00
Lake Superior Car Wheel and Malleable	16.25 @ 16 75

Metal Market.

Pig Tin. — Prices have averaged somewhat below the highest point reached last week. On prompt deliveries 19 50¢ net cash for 5-ton lots was touched. May and later deliveries could have been secured at 0.5¢ @ 0.10¢ discount. From the extreme lowest figures a slight reaction took place toward the close. carload lots having been sold at 19.60¢ net cash during the past few days. There has been very little speculative business and not more than fair average buying for interior account or for consumption. Fresh supplies continue to be quite in line with the consumption. At the close the market seemed quite stiff, with prices on the basis of 19.60¢ @ 19.65¢ net cash for Straits, prompt delivery. Jobbing prices for small lots are unchanged at about 21¢ @ 21¼¢ for Straits Pig and 22¢ @ 22½¢ for Bars.

Copper.—The strike on the Great Northern Railroad has seriously interfered with mining and smelting operations in Montana. That interference, in turn, has caused some operators to purchase supplies in other quarters to fill outstanding contracts. In one instance about 300,000 lb Electrolytic were taken at 9¼¢ for such purpose, and it is understood that other purchases have been made. Apart from this the market is bare of new feature, only routine business being under way in Lake Superior Ingot or Casting Copper. Prices have varied in a slight degree only from 9¼¢ and 9¢ @ 9¼¢ for the respective varieties. The consumptive demand continues moderate and the volume of orders and inquiries received by dealers is still below the average. Prices remain at the level of the past few weeks, with a tendency to harden. Small lots of Lake Ingot from store are quoted at 10½¢ ℔ lb.

Sheet Copper.—Merely a routine business is doing in this material. Orders are mainly for small lots for present use; and there is yet little indication of any general replenishment of attenuated stocks. Cornice makers are waiting for better encouragement from the building industry.

Pig Lead.—Business here has been unimportant and involved only a few hundred tons all told. The transactions were mostly at 3 45¢ @ 3.47½¢, with single carloads at the last named price. There is no change in the general situation save that buyers in this vicinity are more reserved and not bidding 3.45¢ as freely as they did a week ago. Speculative interest is still extremely tame and consumers evince but little interest in buying at the present time. For small lots of Pig 3¾¢ @ 4¢ ℔ lb is the ruling quotation.

Spelter.—Sharp competition, in which two of the largest Western producers figured most prominently, has some-

what demoralized the market, and at present values are very uncertain. Sales have been made of common Western at 3.50¢ delivered here, prompt shipment, and some lots were purchased at 3.25¢ in St. Louis for Eastern account. In the face of this bids were made on 'Change of 3.52½¢ @ 3.57½¢ for July and later deliveries. Latterly there haa been more or less curtailment of production, equivalent, it is estimated, to 25,000 tons per year. This was due mostly to losa in aelling at late pricea.

Sheet Zinc.—The manufacturers have reduced the price of Sheet Zinc atill further thia week. The demand continues quite limited, however, and prices for jobbing quantitiea show no change.

Antimony.—Merely routine business has passed, but enough of it to keep prices quite steady at 8¾¢ @ 8¾¢ for Hallett's and 10¢ @ 10½¢ for Cookson's, with a premium of about ¼¢ on small lots.

Nickel.—The popular price for round lots is 40¢. Small parcela bring 3¢ @ 5¢ more. Only routine demand is experienced here.

Tin Plates.—Aa regards imported Plates, buainess haa been exceedingly slow. Wholesale orders for spot goods have fallen below the average, and in numerous inatances sellers have shaded the prices generally quoted to the extent of 5¢ ₱ box on orders involving only a few hundred boxes. Forward shipments, although offered at somewhat lower prices, have met with very limited sale. In general, the orders received by jobbers run comparatively light, but are, perhaps, more often repeated. Roofing Plates are growing in demand weekly as the building season advancea, and the domestic manufacturers are kept busy in filling orders. Prices for Domestic Plates hold their own in thia market.

In regard to the Western Tin Plate trade, our Chicago advices run as follows: "Tin Plate gives aome indications of a stiffening in price. Spot lots of Roofing Plates and Coke Tin are very firm on account of the smallness of stocks. The American makers are overwhelmed with work and are running behind on deliveries, while stocka in importers' handa are lighter than ever before known. The stocks of large architects have been completely exhausted, as importers will not keep any quantity of thia on hand on account of tariff uncertainties."

A London cable dispatch to *The Iron Age* of April 25, reports that the depression in the British Tin Plate market is more severe after recent improvement. Sellera are yielding slightly to induce business, but make no quotable reduction in pricea. Further concesaions could not be made without positive losa. There is slightly more inquiry for Canada Plates, and some fair orders have been placed for Oil aizes. Liverpool quotationa are as follows:

IC Charcoal, Alloway grade.....12/ @ 12/6
IC Bessemer Steel, Coke finish. ...11/3 @ 11/6
IC Siemens " " " .....11/6 @ 11/9
IC Coke, B. V. grade, 14 x 20.....Nominal.
Charcoal Terne, Dean grade.....10/3 @ 10/6

Wm. A. Stokes & Co., 30 Warren street, New York, are the general agents of the G. M. Shirk Mfg. Company, manufacturers of the North Star Refrigerators. One of the main features of this construction is a combination of dead air space and granulated cork for insulation, for the purpose of economizing the ice consumption. It is pointed out by the makers that the cork will neither settle down nor absorb moisture, and is an excellent nonconductor.

Chicago Report.

Scrap.—The demand for Old Material growa worse inatead of better. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....
No. 2, such as Shovels, Hoes, &c	3.00	....
Old Boilers—whole (Iron)	3.00	....
" (Iron)—cut in single Sheets and Rings	5.00	....
Old Gas-Pipe and Boiler Tubes	5.00	....
Cast Borings	3.00	....
Turnings	4.00	....
Horseshoes	8.00	....
Copper Bottoms	....	5½¢
Copper Clips and Heavy	....	7 ¢
Heavy Brass	....	5½¢
Light Brass	....	3 ¢
Pipe Lead	....	2¼¢
Tea Lead	....	2 ¢
Zinc	....	2 ¢
Rubber	....	3½¢

Anthracite.—Dealers are doing very little now, as it is between seasons. They are, however, watching the progress of the miners' strike with much interest, as stocks will be heavily drawn upon if the strike should continue for any length of time. Carload lots of 12 net tons or over are quoted as follows:

	Grate.	Egg, Sto. and Ch.
Chicago, Ill	$5.00	$5 25
Milwaukee, Wis	5.00	5.25
Kansas City, Mo	8.20	8.45
Council Bluffs, Iowa	8.20	8.45
Lincoln, Neb	8.35	8.60
Sioux City, Iowa	8.20	8.45
Aberdeen, S. Dak	8.25	8.50
Dubuque, Iowa	6.30	6.55
Madison, Wis	6.50	6.75
St. Paul, Minn	7.50	7.75
Burlington, Iowa	6.50	6 75
Des Moines, Iowa	7.95	8.20
Davenport, Iowa	6.30	6 55
St. Joseph, Mo	8.20	8.45
Leavenworth, Kan	8.20	8.45
Omaha, Neb	8.20	8.45

Colorado Anthracite.

COLORADO FUEL & IRON COMPANY.

Denver	$8.00
Pueblo	8.00
Colorado Springs	8.00
Leadville	8.00
Cheyenne, Wyo	10.00
All points between Denver and Missouri River	8.85

Attention is called to the advertisement in this issue of the H. Mueller Mfg. Company of Decatur, Ill. The company are manufacturers of Water and Gas Specialties. Among these are Water Pipe Tapping Machines, which can be used without shutting off the water on the mains or wetting the operator, no matter what the pressure may be. They are described as so easily operated that skilled labor is not necessarily required in making a tap. The Mueller Water Pressure Regulator is another specialty, by the use of which a uniform low pressure can be established in house supply pipes regardless of high or unsteady pressure in the mains. This Regulator is not only useful in preventing the leaking of house boilers by too great a pressure, but it is also valuable in buildings having hydraulic elevatora to prevent the breaking of cablea and to make elevatora run uniformly. The company's line covers Corporation Stop Cocks, brass Water Connectiona, brasa Soldering Nipplea, Round Way Stop and Stop and Waste Cocka, brass Plugs, lead Goose Necka, Check and Waste Hopper Cocks, &c., all their goods being warranted.

CONDITION OF THE

Hardware Trade.

THE VOLUME of business is not as large as last April, and during the month there has not been the increase which was anticipated by some. In view of the general practice of purchasing only such goods as are imperatively required for immediate sale or necessary replenishing of stocks, some merchants are supplying their wants from jobbers rather than from manufacturers to a greater extent than heretofore. At the same time an unusual number of orders for comparatively small quantities are received by manufacturers. In fact, jobbers, manufacturers and commission merchants refer to the number of orders which are received as comparing well with any previous season, while the quantity of goods handled is less than usual. The fact that prices are low has the effect also of still further diminishing the aggregate of business as expressed in dollars and cents. Business on the whole is doubtless in a more healthful condition than for some time, and all kinds of goods are going more evenly into the hands of the trade. Prices show no improvement and in many goods the market is weak. Quotations also from jobbers and manufacturers vary considerably, there being an evident desire on the part of all sellers to obtain such business as is to be had. There continues to be a good deal of cutting of prices on the part of jobbers, some of whom are sending out special quotations to induce orders from houses who have not been purchasing with what they consider sufficient liberality. In this condition of things the judicious purchase of Hardware requires careful attention and constant effort to keep posted as to the changes in price which are occurring. Collections give no ground for complaint.

Advices from Chicago.—Shelf Hardware jobbers report their conntry trade fair, and even their city business is not as dull as had been anticipated when the building strike begun. The past week, in fact, has seen a slight improvement. Orders are considerably more numerous than they were, but they are for small quantities only, showing that merchants are still buying from hand to mouth. Seasonable goods are not active at present. The Refrigerator trade is slow and is not expected to show much improvement until the advent of warm weather. Manufacturers of Wire Cloth are again talking about a shortage. Jobbers are quoting $1.45, and this price is held quite firmly in view of a probable short supply. The demand for poultry netting is large, and manufacturers are considerably behind in their deliveries on contracts. Jobbers' sales this year are practically double those of last year. This is now the hight of the season for this branch of trade. Steel goods are quiet. Haying Tools are moving much more slowly than last year at this time, when the prospects for a heavy hay crop were so bright. Some improvement is noted in the demaud for house furnishing goods, tinners' stock and tinware generally. Mail business is picking up in this line. Heavy Hardware is in a little better demand than last week, but trade is spasmodic, a day of big business being succeeded by two or three dull ones.

Notes on Prices.

Wire Nails.—The demand for Wire Naila continues active and of the aame general character that has prevailed for some weeka. Some large orders are

being placed from time to time, but the great bulk of the business is in orders of moderate size. The mills are fully occupied, but are desirous of having their production for some weeks to come covered by orders in hand, and are consequently moving energetically for such business as is in sight. The price of Wire Nails remains as at our last report, 95 cents for carload lots at factory being a representative quotation, but attractive orders can command 90 cents, a price beyond which we do not hear of any sales. Small lots from store in New York are held at $1.15 to $1.25.

Advices from Chicago.—Manufacturers' agents report city trade extremely dull, but orders are coming in for fair quantities from country merchants. The consumption in the country generally appears to keep up very well. The demand is considerably below what manufacturers would like to see, and they are again making more vigorous efforts to sell. Prices are therefore still drooping, and are now down close to $1 Chicago. Jobbers report a smaller demand from stock, and have lowered their prices for small lots to $1.10 to $1.15.

Cut Nails.—There is little change in the Cut Nail market. Prices are still affected to some extent by Western competition, and in parts of the Eastern territory which are accessible to the Western mills the manufacturers are meeting Western prices and departing to a certain extent from the policy which was adopted some time ago to quote only delivered prices in the several markets. The low freight rates which are prevailing are also favoring the Western mills, as they are at present able to place Nails at points which heretofore they have not been able to touch. The price of Nails delivered in New York is 95¢ to $1 base, small lots from store in New York being regularly quoted at $1.10 to $1.15.

Advices from Chicago.—Manufacturers report a moderate trade, which is fully as large as they have reason to expect at this season. Factory prices are still quoted at 95¢ Chicago on 55¢ average. Jobbers quote small lots from stock at $1.05 to $1.10.

Barb Wire.—The demand for Barb Wire continues fair, but prices are uneven and the tone of the market not so strong as a few weeks ago. The market is represented by the following quotations for Four Point Galvanized, delivered at the points named: Pittsburgh, $2.05 to $2.15; Cleveland, $2.10 to $2.20; Cincinnati or Allentown, $2.15 to $2.25; Chicago or New York, $2.25 to $2.35, but it is probable that these quotations can be shaded.

Advices from Chicago.—Local manufacturers are still full of work, and in some cases are behind with their deliveries on contracts. Eastern manufacturers, however, seem to have caught up with their orders, as their representatives are soliciting trade in this market and promising prompt delivery. Quotations on factory lots of Galvanized Barb Wire are now about $2.15, Chicago. Jobbers report a much better demand from stock than for Nails, and quote small lots of Galvanized at $2.30 to $2.40.

Wire Cloth.—On account of the depression which has for some time prevailed in all lines of business, less than the usual quantity of Wire Screen Cloth was manufactured for the present season. The demand for this article is now setting in actively on the jobbers, and the manufacturers are receiving supplementary orders from those whose purchases were made a few months ago, and the result is that their stock is becoming very short and promises soon to be exhausted. In this condition of things manufacturers who have the goods on hand are advancing their prices with the prospect of still further advances in the near future. The market is thus quotably stronger owing to the scarcity.

Sheet Zinc.—Matthiessen & Hegeler Zinc Company, La Salle, Ill., since the discount sheet on Sheet Zinc referred to in our last issue have sent out two further changes, each being in the way of reduction. The price continues $4.50 for Sheet Zinc in 600-pound casks, of the thicknesses between Nos. 9 to 15, inclusive, and of the widths between 32 to 46 inches, and of the lengths between 84 to 90 inches. The extras are also unchanged. The discounts announced, under date April 18, are as follows:

Discounts.	First class. 15 600-pound casks and upward.	Second class. 10 to 14 600-pound casks.	Third class. 5 to 9 600-pound casks.	Fourth class. Under 5 600-pound casks.
	Per cent.	Per cent.	Per cent.	Per cent.
Special	15	15	15	15
Cash with order	3	3	3	3
Quantity	3	2	1	0
Totals	21	20	19	18

All discounts are computed straight when money accompanies the order. Quantity discount is added to special discount in all cases. If remittance is received within 10 days of date of invoice the cash discount will be only 2 per cent. instead of 3 per cent., and not computed straight. Each order is strictly subject to the quotation of the class to which it belongs.

Glass.—There has been no radical change in the condition of the Glass market during the past week, though prices show an upward tendency. An increase is noticed in the number of factories in operation, which would indicate that manufacturers anticipate an increased demand and remunerative prices. A State organization of Indiana manufacturers has been formed, which has resulted in a stiffening of prices in the gas belt. The New York Window Glass market is represented by the following quotations: Single and double strength Glass in small quantities, 80 and 20 per cent. discount; in 1000-box lots, single, 85 per cent., and double strength Glass, 85 and 5 per cent. discount. Pittsburgh factory quotations are reported as 85 per cent. for single, and 85 and 10 per cent. discount for double strength Glass. New York Plate Glass quotations remain 70 and 10 per cent. discount.

Old Metals.—Business is hardly as good as it was a week ago. Some grades of Scrap Iron are, however, in fairly good demand, but bids are below the views of holders. Trade is consequently checked. Prices are irregular and somewhat weak. The following quotations represent about the ruling rates in New York:

Heavy Copper	℔	7½¢
Light and Tinned Copper	℔	6½¢
Heavy Brass	℔	5½¢
Light Brass	℔	4½¢
Lead	℔	3¢
Tea Lead	℔	2¢
Zinc	℔	2¾¢
No. 1 Pewter	℔	14¢
No. 2 Pewter	℔	7¢
Wrought Scrap Iron, ℔ gross ton	$9.00 @	....
Heavy Cast Scrap, ℔ gross ton	7.00 @	....
Stove Plate Scrap, ℔ gross ton	4.50 @	....
Burnt Iron, ℔ gross ton	3.00 @	3.50

Old Rags, Paper, &c.—There has been a more active demand, and prices for Paper stock and Woolen mill supplies are pretty steadily maintained. Quotations as follows:

No. 1 White Rags	℔	lb 3¼ @	3½¢
No. 2 White Rags	℔	lb 2 @	2½¢
Mixed Rags	℔	lb	2¼¢
Blues and 3ds	℔	lb 1 @	1¼¢
Hard Sized White Shavings	℔	lb 2¼ @	2½¢
No. 1 White Book Shavings	℔	lb 1¾ @	2 ¢
No. 2 White Book Shavings	℔	lb 1 @	1⅝¢
Light Book Shavings	℔	lb	¾¢
No. 1 Mixed Shavings	℔	lb ¾ @	1 ¢
No. 2 Mixed Shavings	℔	lb ½ @	¾¢
No. 1 Printed Books	℔	lb 1 @	1¼¢
Ordinary Mixed Books	℔	lb ½ @	¾¢
Newspapers	℔	lb 2-5 @	½¢
No. 1 Manila Paper	℔	lb 1 @	1⅛¢
No. 2 Manila Paper	℔	lb ⅝ @	¾¢
Bogus Paper	℔	lb	½¢
Common Paper	℔	lb	⅜¢
Straw Chips	℔	lb	½¢
Binders' Clippings	℔	lb ½ @	⅝¢
Jute Butts	℔	lb 1⅞ @	2 ¢
No. 1 Jute Bagging	℔	lb 1 @	1¼¢
Mixed Bagging	℔	lb ¾ @	1 ¢
No. 2 Bagging	℔	lb ½ @	¾¢
Hemp Twine	℔	lb 2 @	2¼¢
Manila Rope	℔	lb 2¼ @	2⅜¢
Jute Rope	℔	lb 1½ @	1¾¢
Mixed Rope	℔	lb ¾ @	⅞¢

Old Rubber.—The market for Old Rubber is fairly good. Prices rule about as follows, but are subject to variation and are somewhat irregular:

Car Springs, ton lots, ℔ lb.	.... @	$0.03½	
Rubber Shoes, carloads, delivered at factory, ℔ lb.	.... @	.03⅛	
Rubber shoes, less than carloads, ℔ lb.	@	.03¼	
Large Hose, ℔ ton	.... @	12.00	
White Wringer Rolls, ℔ lb.	.... @	.03¾	
White Syringes, ℔ lb	@	.03¾	

Trade Notes.

An unusually striking announcement is made elsewhere in this issue by the Perfection Furnace Pipe Company, Broadway and Logan street, Toledo, Ohio. In the two-page display they show a large number of goods that are of interest to the trade, and those who have use for such articles are invited to send to the company for their catalogue and price-list.

The announcement elsewhere of N. & G. Taylor Company, Philadelphia, Pa., relates to Columbia guaranteed Terne Plate, which is described as a high grade, heavily coated Terne Plate, made from the finest quality of rehammered Siemens-Martin soft steel. The sheets are resquared and stamped.

The contract for all the Steel and Iron Work for the new Pulaski County jail, at Dublin, Va., was recently awarded to E. T. Barnum, Detroit, Mich.

The Excelsior Steel Furnace Company, 38 West Monroe street, Chicago, make an interesting announcement in their advertisement in this issue.

Occupying part of their space is a coupon which will be received by them as the equivalent of $1 in payment for a first order of Furnace Stacks or Fittings amounting to $10 or more. The company manufacture all kinds of fittings, and are prepared to fill orders as soon as received.

Among recently chartered corporations in New York State is the Glazier Headlight Company of Rochester. N. Y., to manufacture Headlights, Lanterns, and Sheet Metal Goods. The directors are: Elias C. Glazier, Nellie A. Glazier, Frank P. Siddons, and others of New York City. Capital $6000.

The building now under erection by the Canton Rolling Mill Company, Canton, Ohio, is rapidly approaching completion, and is expected to be finished about July 1 next. The new concern will engage in the manufacture of Iron and Steel Sheets and expect to turn out from 25 to 35 tons per day. The building is of iron and is being erected by the Canton Bridge Company of Canton, Ohio. The rolls are being furnished by the Lloyd Booth Company of Youngstown, while Wm. Tod & Co. of the same place will supply the engine, and Reeves Brothers of Alliance, Ohio, have the contract for the boilers.

The Chester Pipe & Tube Company, Chester, Pa., give notice of a proposed increase in their capital stock. It is said that this action has been in contemplation for over a year, and that advantage will now be taken of the very low prices of materials to make the improvements which the management has had in mind.

The American Sheet Iron Works, Philipsburg, N. J., were again shut down this week for lack of orders.

The McDaniel & Harvey Company's mills, at Wilmington, Del., and at North East, Md., are running full on orders for Sheet Iron.

Cost of Melting.*

There is probably less known about the actual cost of melting iron in cupolas for foundry work than about any other branch of the foundry business. But few foundrymen make any attempt at keeping a cupola or melting account. Many of those who do, keep it in such a way that they not only fail to learn the cost of melting, but are misled by the account to suppose their melting costs them a great deal less per ton than it really does. In the majority of foundries the melting is left entirely in the hands of the melter, who as a rule has no system for doing the work, and has no control over his assistants or interest in having them do a fair day's work. In many of the foundries I visit twice the number of men are employed as cupolamen as are employed in melting the same amount of iron in other foundries, where the facilities for handling the stock are almost the same, and the expense of lining and daubing material is frequently double with one melter what it is with another in the same sized cupola with the same sized heats.

In many foundries the fuel is not weighed, but is measured in baskets, or the number of shovels counted and the weight estimated. When the fuel is measured in baskets the baskets always stretch and enlarge, and an old basket frequently holds one third more than a new one; from 10 to 20 pounds more can easily be piled on the top of a basket after it is filled. Foundrymen who charge their fuel by the basket always use more fuel than they estimate they are using; when the shovels are counted, each shovel may be made to weigh more than is estimated, and a few extra shovelfuls are always thrown in, for fear some were not full. When too much fuel is used in a cupola there is not only a wastage of fuel, but there is slow melting, increased destruction of the lining and an increased wear and tear of the blast machinery. For these reasons every pound of fuel that goes into the cupola should be accurately weighed. Even when the fuel is supposed to be accurately weighed there should be some check on the melter, for he will shovel in extra fuel if not watched.

At a foundry I recently visited in New Jersey an accurate account of the melting had been kept for a year. At the end of the year the president of the company had figured up the amount of fuel consumed in the cupola and compared it with the amount purchased, and found they were short 260 tons. At another foundry, where the melter always reported melting 7 pounds of iron to 1 pound of anthracite coal, they ran short 300 tons in a year. This kind of work should be prevented by checking up the melter's report and comparing it with each carload of fuel consumed.

A cupola book should be provided, with blank spaces for recording the weight of coal or coke in the bed and charges, and the weight of each brand of iron, No. 1, 2 or 3 and scrap, showing the exact mixture of each charge and heat. A note should also be made of the quality of iron produced from the mixture. Such a record is of great value in making mixtures and charging a cupola, if it is properly kept.

The cost of melting per ton is figured in a number of different ways, but to be of any practical value the entire cost of melting should be figured on as follows:

Interest on cost of cupola plant and depreciation in value of same.

Fire brick for relining and repairs.

Fire clay, loam and sand for cupola and ladles.

Repairs to cupola, blast pipe, elevator, scaffold, runway, blower, &c.

Belts, oil, &c., for blower.

One-fourth the entire cost of engine.

Tools, wheelbarrows, buckets, hose, shovels, forks, rakes, hoes, sledges, picks, bars, trowels, bod sticks, tap bars, &c.

Wood for lighting up and dredging ladles.

Coal or coke consumed in melting.

Labor employed in removing the dump, making up cupola, milling dump and gates, collecting gates, scrap and bad casting from foundry, placing iron and fuel on scaffold, charging, breaking and piling iron in yard, breaking up bad castings, daubing ladles, &c.

When the cost of all these items has been learned, and the amount divided by the number of tons melted, it will be found that the cost of melting is about $2 per net ton of iron in the ladles. In foundries with all the modern improvements for handling the stock the cost is a little less than $2 per ton, and in foundries with none of the improvements for handling the stock and no system in melting the cost per ton is as high as $3. When there is doubt as to the accuracy of weights in charging, the weights should be compared with the fuel purchased and castings sold, and the cost of melting may be figured on the weight of castings sold in the place of the amount of iron melted. To make a cupola report of value the fuel, labor and tool accounts should be kept separate, and an effort made to reduce the expense of each account.

* Paper by Dr. Edward Kirk, read at the last monthly meeting of the Western Foundrymen's Association.

A Word About Valves.

Nothing is more essential to successful steam and hot water heating work than reliable valves. Unfortunately, the intense competition for heating contracts of late years has fostered a disposition on the part of contractors to buy everything of the cheapest; and thus has been created a demand for cheap valves. Now it is a fact that a good valve cannot be produced within a certain limit of cost, and if this line be passed, the quality of the article, while it may suffice for a brief period of use, is sure to give no end of trouble long before a good valve should manifest any symptoms of failure. For instance, a pair of new valves fitted to a steam radiator last fall, though receiving no extraordinary usage, now leak so badly that, when closed, the radiator fills with water and when steam is let on the radiator becomes a "thunder box." The best valves obtainable still have some defects that it would be desirable to remove; the cheaper, poorer varieties are, many of them, all defects.

Weight in Valves.

If a valve body be cast too light it springs easily, and pressure on the seat when closing it causes the seat to yield permanently: it will then leak till the faces of both disk and seat are again ground to fit and will soon give way again in use. A brass globe valve used in a brewery burst by freezing not long ago. Examination of the structure showed so little thickness in the walls of the globe as to render it surprising that it could have been cast so thin. Inquiry disclosed the fact that the valve had leaked almost from the beginning of its use; and doubtless this was expected by the makers, who presumably know enough about valves to understand what has been said above, and who would justify themselves for making inferior goods by the assertion that they would not make them from choice, and do so only because the trade has set up a demand for them. The excuse is valid. Manufacturers must meet the demands of their trade or go out of business.

Can a Hard Seat Valve Close Tight?

There are steam heating engineers who assert that all hard seated valves will leak a little, no matter how well made, unless, after the first closing, they are tightened down again when the stems have cooled. That in cooling after closing the contraction of the stems relieves the pressure of a valve disk upon its seat is certain; whether this is sufficient to slightly open the valve depends probably somewhat upon the elasticity of the material. If the elasticity be sufficient to compensate for the contraction the valve should remain tight; but it would be a very nice job to so relate the elasticity to the contraction as to absolutely insure that a hard seat valve shall remain perfectly tight with once closing. The rule is probably, as the engineers referred to assert, that hard seat valves cannot be relied upon to remain absolutely tight. But the fact is that before the era of cheap valves those with hard seats did give reasonably good service.

Procrastination.

Business and manufacturing houses, like men, have their characteristics, their vices and their virtues. Generally these can be traced to the managing man and his character found reflected in all the actions of the concern as a corporate body. But frequently, through years of continuance in certain methods and customs, the entire establishment becomes satnrated with the spirit of him who governs, and remains so long after his departure, notwithstanding the earnest efforts of his successors to turn it from its course. Procrastination, that everlasting habit of putting off things until some other time, whereby everything is always just so far behind, stands out as prominent in many a concern as it does in a multitude of men. The delay of the cobbler and the tailor we somehow take as a matter of course, but the otherwise reputable concern that delays and exasperates us in the greater things of life we frequently set down as unworthy of confidence and our further patronage. The strange thing about procrastination is that it seems only necessary to catch up once for all and then orders would continue thereafter to be filled on time. But the habit once formed is not so easily conquered, and the concern is soon back in the old rut again. Some managers appear to work on the principle that it is best to be just a little behind time, so that there may be urgent cause for rushing the men and thereby getting more work out of them. It takes but a short time and a very moderate intellect to see through the game, however, and therefore the workman's actions are governed accordingly. The waste of material through haste, the poorer resulting workmanship, the additional cost of explanatory letters and telegrams or the time spent in making personal apologies for delay, go far to show the disastrous financial effects of procrastination. The habit will be hard to break and rules will be difficult to follow, but success will attend only when—1. No promises are made that cannot be fulfilled. 2. A sufficient stock of material is kept on hand or the same is ordered promptly enough to cause no delay for lack of it. 3. One thing at a time is completely fiuished, instead of dropping one job to take up another, because of the importunity of a customer. 4. A thing is pnt out of sight as soon as it is completed. And finally by such careful planning of the work no time is lost; jobs are started in time to be completed at the desired date and a man's abilities are always utilized to the best advantage.

The closing exercises of the evening educational classes of the Young Men's Institute were held on the evening of May 1 in the lecture room of the institute, 222 Bowery, New York. The Rev. Dr. MacArthur delivered the address of the evening, in which he urged the students to be ambitious and keep up their good work. Forty-six diplomas were awarded, and certificates of progress were given to 23 scholars. The presentation of prizes and diplomas was made by W. M. Kingsley, who presided. Prizes were given for efficiency in arithmetic, freehand and mechanical drawing, shorthand, steam engineering and electricity, &c.

A decision affecting nearly every railroad in the country using steam heating in passenger cars was recently handed down by Judge Swan of the United States Court at Detroit against the Michigan Central Railroad. The decision sustains a patent granted to E. D. Cody in 1885, and owned by the Consolidated Car Heating Company of Albany, N Y., on a system of car heating. It holds as an infringement the heating system known as the Martin apparatus, now used by the railroad referred to. The decree grants an injunction against the further use of such steam heaters.

The Madrid correspondent of *Industries and Iron* says that the price of petroleum has been raised lately in Spain to such a point that those who previously used the oil for lighting purposes are now employing electricity.

THE LETTER BOX.

Check Dampers.

From C. E. S., *Clinton, Iowa.*—I would like to hear from the readers of the paper in reference to check dampers used in the smoke pipes of different kinds of hesters. There are two kinds primarily—the first simply turns into the pipe and stops or retards the passage of the products of combustion; the other leaves an opening in the pipe through which the chimney is supplied with air, and stops its draft on the fire. A third kind is a combination of both of the above features, opening into the pipe, partially shutting off the passage and also permitting air to enter to cool the pipe and supply the chimney. The second style of damper mentioned cools the pipe much more than the first, and it is said that there is no loss or waste of heat going up the chimney. Is this true? Do these dampers hold the heat in the hester or do they make the fire slow? It is true that with this method the pipe cools, but is it not caused by the cold air entering? What is the best damper? Is there any difference, and if so, why? Where is the best place to put a furnace damper, next to the heater or next to the chimney? These are questions which are only partly decided in my mind, and I think a discussion of them would be interesting to other readers than myself.

Defective Draft.

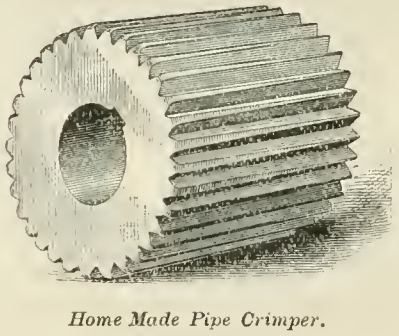
From W. S., *Danville, N. Y.*—I would be glad to receive suggestions from *The Metal Worker* and its readers as to what causes the trouble in two faulty chimneys that are here described: The first chimney is 4 x 12 inches in size and has two stoves connected with it, one pipe hole being 18 inches above the other, the stoves being placed on opposite sides of the chimney in different rooms. The stove which is connected at the lowest opening has a very poor draft, while the one at the highest point has a fair draft. The chimney creosotes so badly that it runs down on the outside of the stack on to the roof and spoils the water which is used for laundry purposes. The chimney is increased in hight by a 7-inch stack, which runs up several feet higher than any of the surrounding buildings. The fault is not with the lower stove, as it worked perfectly when connected with another chimney.

The other chimney has but one stove connected with it, but it creosotes much more than the first chimney. It runs down into the smoke pipe and forms a crust that eats up the pipe in from four to six months. The stove is connected to the chimney by the use of two 45° elbows, so as to give the smoke an easy turn, and there are 2 feet of pipe between these two elbows. What puzzles me is that everything worked first-rate for the last eight years, or up to within a year ago, when the trouble began. The chimney is as high as any of the surrounding buildings, but there are several trees in front of the house, 25 feet from the chimney and possibly 10 feet taller. I shall be greatly obliged for suggestions, and hope some of the readers will give me a pointer or two.

Note.—We trust our readers will discuss this subject. It would seem to us that the first chimney was entirely too small and of a wrong shape to do good work, particularly with two stoves, and from the fact that the smoke cannot get up the chimney fast enough it condenses on the sides of the chimney and makes the trouble reported. The dimensions of the second chimney are not given, but a consideration that would be likely to affect both chimneys is the eating out of the lime in the mortar which cements the brick work, when air would enter to interfere with the draft.

Home Made Pipe Crimper.

From B. C. & Co., *Philadelphia.*—This winter, not being very busily engaged, I concluded I could make a stove pipe crimper of my swedging machine, and made two crimping rolls that would fit on the shafts of the machine for the purpose. I made a pattern of sheet zinc, and when I took it to the foundry I showed it to the foreman and finally asked him if he could make two castings that would be perfectly true from that pattern, and then dropped the pattern in his hand; and as he expected some considerable weight, he nearly threw the pattern in my face because it was so light and made an ejaculation of surprise to find that it weighed so little. There were extensions on the pattern for the core prints, and when I received the castings they had a hole through the center, as shown in the sketch. After the castings were received I filed a slot in the pole to fit over the key on the shaft, and left the edges sharp on one end; but at the other end they were ground flat and round, so that the pipe would not be cut by the machine. These are now slipped on the shaft of my swedging machine, and I can crimp stove pipe first rate. The total cost, without counting my time, was less than 60 cents.



Home Made Pipe Crimper.

The Bell Vapor Stove.

From G. P. M., *Boston, Mass.*—Will some one please give me the address of the maker of the vapor stove which carries on the tank the name "Bell?"

Copper Gutters for a Round House.

From C. B., *Conneaut, Ohio.*—I am interested in a controversy as to whether or not copper is the best metal to use for gutters and cornice work on slate roofs. I have a job on hand that calls for gutters and flashings of 16-oz. copper. I shall be glad to have the readers of *The Metal Worker* give their experience with the use of copper in this connection. I have seen a job of copper gutter work that was put on a round house in 1882, which was torn off within the past year because of its going to pieces, but I do not know what metal was substituted. Lead has been suggested as a better metal than copper.

Note.—We trust our readers will discuss this subject, which is very interesting. No doubt the gases arising from the locomotives in a round house subject the copper to conditions which are different than those which would exist on an ordinary roof exposure. There are a number of buildings in this country having copper roofs which have been in use for more than 100 years, Christ Church of Philadelphia, which has never been painted, being a case in point. The City Hall in New York City is covered with a copper roof, which was put on in the usual standing seam form and has been in use about 50 years. In both cases copper is used for the roof as well as the gutters, the City Hall being exposed to what might be called a salt atmosphere, while the church is so far inland that it is not exposed to the same climatic effect, although the Delaware River prevents the climate from being dry.

Sheathing for Tin Roof.

From A. P. B., *Central Nassau, N. Y.*—In reply to the inquiry of "B. J. T." in *The Metal Worker* of April 14, with reference to sheathing for tin roofing, would give my experience as follows: I have laid a number of thousand feet of tin with the sheathing 2 inches apart, but would advise that the tin be painted on both sides before laying; then there will be no rust between the sheathing boards. I would suggest that he get prepared tin that is all ready for the roof and would advise him to use 20 x 28 redipped tin.

Why Did the Boiler Collapse?

From ZERO, *Riverhead, N. Y.*—Will *The Metal Worker* please ask its readers to explain what caused a copper range boiler to collapse under the following conditions? It was supplied with water from the town main and was in constant use up to 10 o'clock at night, when, on account of zero weather, the water in the house was shut off over night. In the basement below the

boiler there is a set of soapstone washtubs and a water closet. Hot water is drawn from the boiler for the tubs. After the water was shut off from the water main, the bibbs in the washtubs were opened to allow the water in the pipes to run out in order to prevent freezing. The boiler has a usual delivery tube in the center with a hole in it near the top to prevent syphonic action.

Wants to Learn Brazing.

From A. C. R., *Newark, N. J.*—Please let me know through *The Metal Worker* the methods employed in brazing, as followed in railroad repair shops.

Answer.—Too much space would be required to give a comprehensive answer to the questions asked, and we would recommend our correspondent to get a copy of "The Art of Coppersmithing," which can be supplied by the book department of this office.

Hanging Long Gutters.

From O. J. B., *Troy, Ind.*—I send to *The Metal Worker* my method of hanging long gutters and would like to hear from some of my brother tinners on the same subject. Many different styles of eaves are met with, and different styles of gutter and hangers are used. In hanging gutter on a barn 80 feet long I would put up the gutter in two sections of 40 feet each. When the eave projects considerably without any back strip nailed to the end of the rafters, I always have one put up 6 inches or more wide according to the pitch of the gutter. Then I nail my gutter straps to it about 2½ feet apart. I make them out of good tin painted on both sides, and cut them 1 inch wide and 28 inches long. At the center of the strap I rivet or solder another strap half as long to hold the gutter from being lifted up in a wind storm. Having nailed up the straps make a loop of one, as shown in the illustration, about 10 feet from the high end of the gutter, for the work should always commence at the high end. Now place the ladder about 20 feet from the end and pick up a section of the gutter at the middle of the 40 feet and mount the ladder, when if it is not a windy day one end of the gutter can be easily pushed through the loop and the gutter secured by another loop near the ladder. After this, by moving the ladder the other straps can be fastened so as to give the gutter a proper pitch, and the first section is completed. The second section is put up in the same way, and when it is secured the two sections are connected and the straps fastened to maintain a proper pitch through the entire length. When all is securely fastened the open seam between the two sections must be soldered; this completes the work ready for the conductor to be attached to pipe at the low end of the gutter. I sometimes solder the down straps under the bead of the gutter about 10 feet apart, and when properly nailed they hold the gutter securely in place, and the strongest wind will not lift the gutter out of the straps or destroy the pitch.

Hanging Long Gutters.

Fails to Bake on the Bottom.

From H. F., *Chicago.*—I have read the different letters that have appeared in *The Metal Worker* in answer to the inquiry of "W. F.," in the issue of January 20, with considerable interest. Two primary causes for cooking stoves failing to bake are bad fuel and bad management. I have used a large number of stoves during the last 20 years, and have never had any serious trouble in making any stove or range bake on the bottom. There are all kinds of coal on the market and also all kinds of stoves. Very poor fuel is not likely to give satisfaction used in a very cheap stove, and the very best stove made, set up to a good flue, will not work well unless managed properly. Dealers are generally willing to give the instruction necessary for the proper working of a stove, and it is very important that they should do so. I was recently informed by a woman who has a stove that had an excellent reputation that she had used it for three years without cleaning the flues, not even knowing that the flue stop could be removed. Consequently it had failed to give satisfaction, and, to use her own expression, "the stove was good no more." I have used the same kinds of stoves in different chimneys, and have found the stove to work best where the draft was good. From my own experience, I believe that the ranges made by some firms will give better satisfaction than those made by others, and that a well made range of the sheet flue type will cure many faulty chimneys. I always select stoves having full deep flues and an ample fire chamber, and never have any trouble to make them bake on the bottom.

What is a By-Pass?

From A. J. C., *Morristown, N. J.*—Will you please explain in *The Metal Worker* the meaning of a by-pass, as relating to plumbing work? I have read of it quite often, but could never find out the meaning of it.

Answer.—A by-pass is a branch from a main which extends past some fixture and enters the main beyond it. Two stop cocks are placed upon the main between the two by-pass connections, and a branch to some other fixture is taken off between these two stop cocks. When no water is desired in this branch both of the stop cocks on the main are closed and the stop cock in the by-pass connection opened. By this means the water passes by the branch and continues to supply the other fixtures on the main.

Rust Preventive.

From YATES & Co., *Rockford, Ill*—If "A. L. H.," Woburn, Mass., whose letter appeared in *The Metal Worker* April 21, will send us his address we will mail him a pamphlet telling him how to make a rust proof application at 37 cents per gallon, and a first-class paste stove polish at from 3 cents to 6 cents per pound.

OBITUARY.

BIRDSILL HOLLY.

Birdsill Holly, inventor of the Holly system of water works, died at his home in Lockport, N. Y., April 27. He was born in Auburn, Cayuga county, N. Y., October 8, 1820. He received a common school education and then worked at general mechanics and as millwright. After becoming an expert in all kinds of general mechanical work he went to Uniontown, Pa., where he first became superintendent and afterwards proprietor of a large machine shop, which he conducted for a number of years. He then returned to Seneca Falls, N. Y., where he became a member of the manufacturing firm of Silsby, Race & Holly. They produced hydraulic machinery. In 1859 he removed to Lockport, where he resided until his death. He gave his time to the inventions which have made his name far known. He invented a chain stitch sewing machine which had a large sale. He invented and perfected over 150 devices. Some of these in machinery were bought in Europe, where they are now manufactured. But the invention with which his name will always be identified is that of the Holly system of water works. The builders of the systems of engines and pipes, the Holly Mfg. Company, organized in 1859, have now a capital of $1,000,000, employ 500 men, and their works occupy over two blocks in Lockport. They have already placed their system in over 2,000 towns and cities of the United States and Canada, where it is now in successful operation.

The recently enacted anti-monopoly law of the State of Illinois does not appear to operate satisfactorily, if it be true, as stated, that over 15,000 corporations in Illinois have neglected or refused to make a report to the Secretary of State, according to its provisions. About 10,000 only made full reports, while several thousands evaded the law by taking out certificates of dissolution. According to the law the Attorney-General is now bound to bring actions against the 15,000 delinquent concerns, a sufficiently arduous task.

The negotiations for a proposed transatlantic steamship pool have fallen through and will not, it is said, be resumed. A rate war in steerage passenger traffic has been inaugurated between the British and Continental lines of steamers.

THE RETAIL STORE.

The Thomas Hose Nozzle and Sprayer.

The accompanying cuts represent a hose nozzle and sprayer combined, offered by John H. Thomas, Piqua, Ohio.

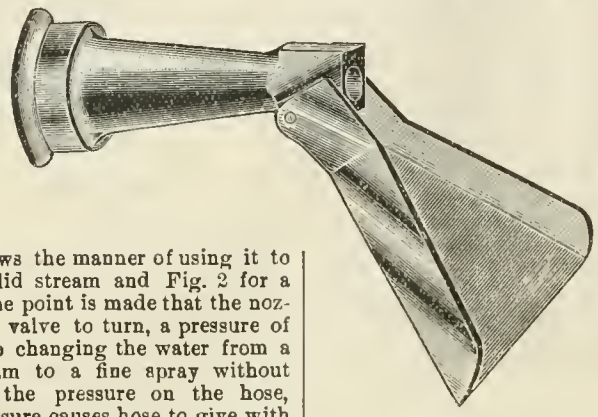


Fig. 1.—The Thomas Hose Nozzle and Sprayer.

Fig. 1 shows the manner of using it to throw a solid stream and Fig. 2 for a spray. The point is made that the nozzle has no valve to turn, a pressure of the thumb changing the water from a solid stream to a fine spray without changing the pressure on the hose, which pressure causes hose to give, with a tendency to collapse. The nozzle is designed for street sprinkling, watering

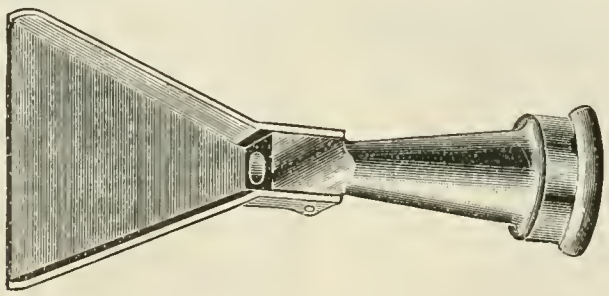

Fig. 2.—Position for Spray.

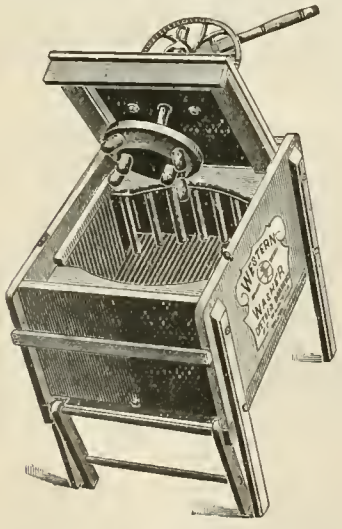
flowers, lawns, washing buggies, &c., or for any purpose for which a hose is used.

The Western Standard Washer.

Diether & Barrows, Fort Wayne, Ind., are offering the washing machine shown

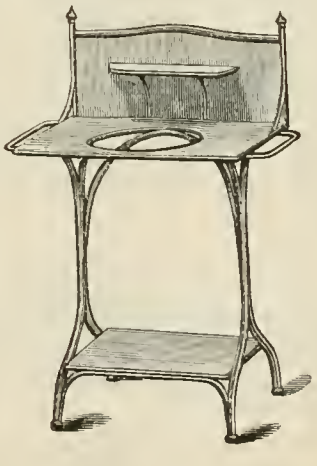


The Western Standard Washer.

in the accompanying cut. An important feature of the machine is a galvanized steel shifting shaft, to which a rubber or pin wheel is attached. The shaft is described as having a free perpendicular movement through the gear wheel, quickly adjusting the rubber or pin wheel to any quantity or condition of the clothing in the washer. The manufacturers claim that the galvanized steel shafts will not shrink, swell, rust, rot, split or break, and that the gearing will adapt itself to a single piece or a tubful, washing any intermediate quantity to perfection. The washers are made in sizes Nos. 2 and 3.

Japanned Toilet Stand.

One of the latest productions in the line of sheet metal furniture is the ja-



Japanned Toilet Stand.

panned square toilet stand, shown in the accompanying illustration. The stand is manufactured by the Lalance & Grosjean Mfg. Company, 19 Cliff street, New York, by whom it has just been placed on the market. Made of sheet steel, the stand is light, yet durable, and is specially adapted for country house or camp use. It is japanned of an ivory white color, resembling enamel, and is easily kept clean, presenting at all times a neat and tidy appearance. It is fitted for the accommodation of all the toilet requisites, and possesses the additional recommendation of economy of space, being but 42 inches high and 30 inches wide.

Hanks' Water Filter.

Bigelow & Dowse Company, Boston, Mass., as exclusive agents for the Hanks Filter Company, are introducing

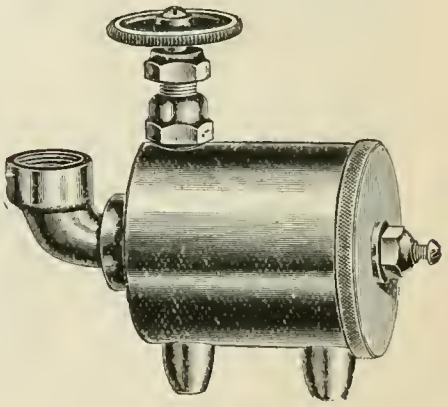


Fig. 1.—Hanks' Water Filter.

the filter shown in the accompanying cuts. The filter is of cast brass, nickel plated, the body being 3 inches long and 3 inches in diameter, and designed to attach directly to the faucet of the water supply pipe. From Fig. 2 it will be seen that the connection with the faucet is made at the elbow, at the left of the cut. To the right of the stop cock is a carbon block, $\frac{7}{8}$ inch thick, which fits the inside walls of the

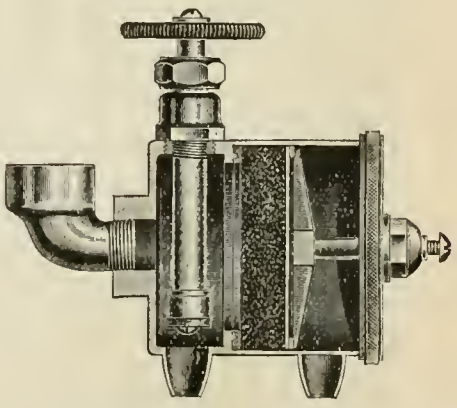

Fig. 2.—Interior of Hanks' Water Filter.

filter closely. This is held closely against the rubber gasket on the flange, by a set screw pressing against a brass spider. Access to the interior of the filter is gained by unscrewing the cap which forms the covering of the right hand end. The position of the carbon, it is explained, is such that it is kept

clean by the water rushing in when the stop cock is raised, the water and dirt thus leaving the filter by the tube immediately beneath the stop cock. To filter the water the stop cock remains closed, and the water is forced through the carbon and out of the other tube. Should the pressure be insufficient to keep the carbon washed clean, it may be removed and the surface cleaned with sand paper. The advantage claimed for the filter is that the filtering surface is easily kept clean, consequently the water is not forced through accumulated filth collected on the filtering surface.

The Matchless Coffee Pot.

Hill & Whitney Mfg. Company, 149 Pearl street, Boston, are offering a coffee pot as shown herewith. It is made with a filter which can be raised or lowered by means of a chain attached to it,

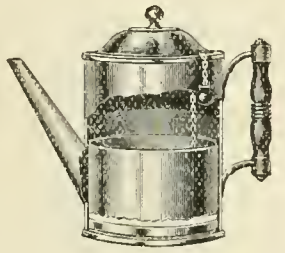

Fig. 1.—The Matchless Coffee Pot.

and which can be removed. For filtering, common unbleached cotton cloth is used, torn or cut in squares about an inch larger than the cylinder bottom, and secured on the bottom of the filter by means of a screw cap. In use the filter is placed at the bottom of the pot as in Fig. 1, into which fine ground coffee is put, and on which is poured the desired quantity of boiling water. After the pot has stood on the stove seven to ten minutes the filter is raised as in Fig. 2, and suspended by catching the hook on the chain over the rim of the pot. As soon as the liquid has passed from

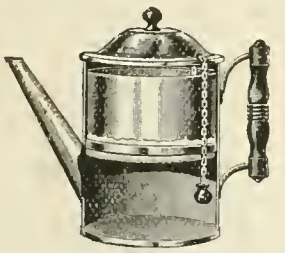

Fig. 2.—Filter in Coffee Pot Raised.

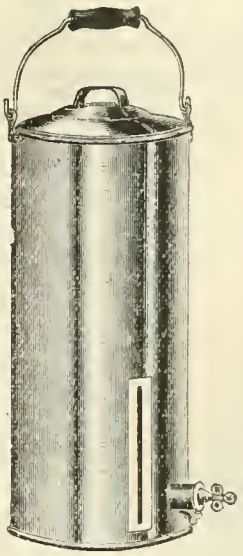
the filter, which requires two or three minutes, the coffee is considered ready for use. The advantages claimed for the process of first steeping and then filtering the coffee are as follows: That the grounds and water are quickly and perfectly combined and remain together steeping as long as is desired ; that in the use of a filter practically of as large an area as the pot a close texture of cloth can be used, permitting the use of fine ground coffee, resulting in economy of time and material and the production of a clear extract, and that by daily renewals of the filter at a cost of from $\frac{1}{2}$ to $\frac{1}{8}$ cent for each cloth, a uniform and excellent beverage is always obtained, free from all disagreeable taint. The manufacturers state that the pot is also especially adapted to making tea.

Maine Creamery Can.

Portland Tinware Company, Portland, Maine, are offering the creamery can shown here. It is referred to as being made of the best quality of tin, extra heavy, well made, and is provided with a glass gauge and metal faucet. The



Maine Creamery Can.

faucet is set 1 inch from the bottom, to allow the milk to be drawn off until the cream is reached, then to draw off the cream, leaving an inch of milk in the bottom of the can with the sediment undisturbed. The can has been put on the market to take the place of a high priced can.

Central Filter Cooler.

The Central Stamping Company, 23–25 Cliff street, New York, are offering the Central filter cooler, as shown in Figs. 1 and 2. Fig. 1 represents the filter in position. Fig. 2 shows the filter cylinder detached. The cylinders are made of galvanized iron and fitted with a carbon block filter, so arranged as to be easily removed for cleaning.

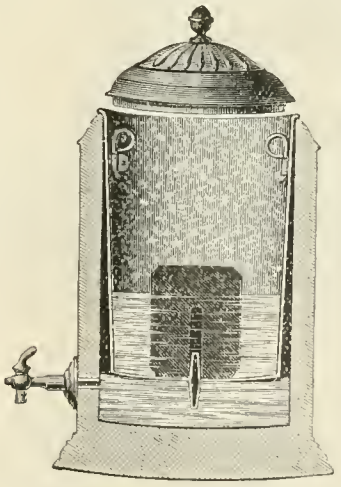


Fig. 1.—Sectional View of Cooler, Showing Filter in Position.

The ice and water are put into the cylinder, filtering through the carbon and tube into the cooler, to be drawn off through the faucet at will. The prominence given to purer drinking water by specialists of late years as a means of avoiding disease has stimulated the production of many forms of filtering apparatus more or less expensive. The filter here shown has been devised to

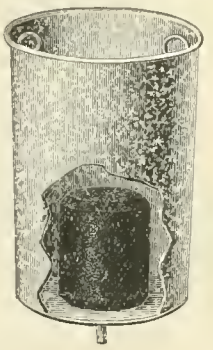

Fig. 2.—Showing Filter Detached.

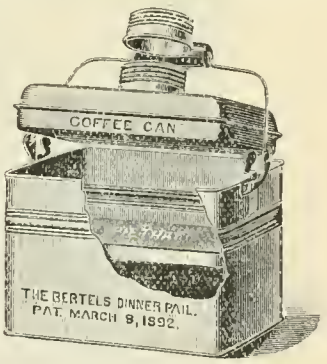
accomplish the result sought at comparatively slight expense. The cylinders are made in seven sizes, from 2 to 14 gallons capacity, and will fit any of this company's regular coolers.

Screw Cup Dinner Pail.

The accompanying cut represents a dinner pail with a screw cup offered by W. B. Bertels, Son & Co., 186 East Market street, Wilkes-Barre Pa. The opening at the top of the coffee can is large enough to admit of the hand for easy cleaning, and the manufacturers claim that the coffee cannot leak or slop out when the cup is screwed on. The ears are provided with springs for holding the coffee can in place. The manu-



Screw Cup Dinner Pail.

facturers state that the material and workmanship are good, that the design of the pail is attractive, and that the coffee can is large. The pails are made in three sizes : small, medium and large.

Buckeye Pruning Shear.

The Peck, Stow & Wilcox Company, 27 Chambers street, New York, have improved their French pattern pruning shear by substituting a volute for the coil spring. The volute spring is made of a spiral scroll of steel plate extended in the direction of the axis of the coil, in which direction its elastic force is extended. The company claim for this method quickness and ease of action, while the combination of spring and shape of frame permits the shear to open sufficiently wide to take in a large stick without cramping or tight action when the blades are closed. It is especially adapted to grape culture and florists' uses. This shear is made in one size, 9 inches long, and will be known as Buckeye No. 99. They still make as heretofore the three sizes of the French pattern with coil springs.

ROOFING AND CORNICE.

Elaborate Sheet Copper Work.

The illustrations shown herewith represent, Fig. 1 front elevation, Fig. 2 side elevation and Fig. 3 plan view of a dormer in the shop, corresponding to the bevel of the mansard roof. The cheeks or sides of the dormer are of copper, and were riveted to the dormer at the building after the dormer was set and the roof slated. The roof of the dormer dered on the outside was first wiped clean with a damp rag to remove the acid, then dried. When dry the entire dormer was coated with linseed oil by means of a woolen rag soaked with oil. After this was dry the outside soldered

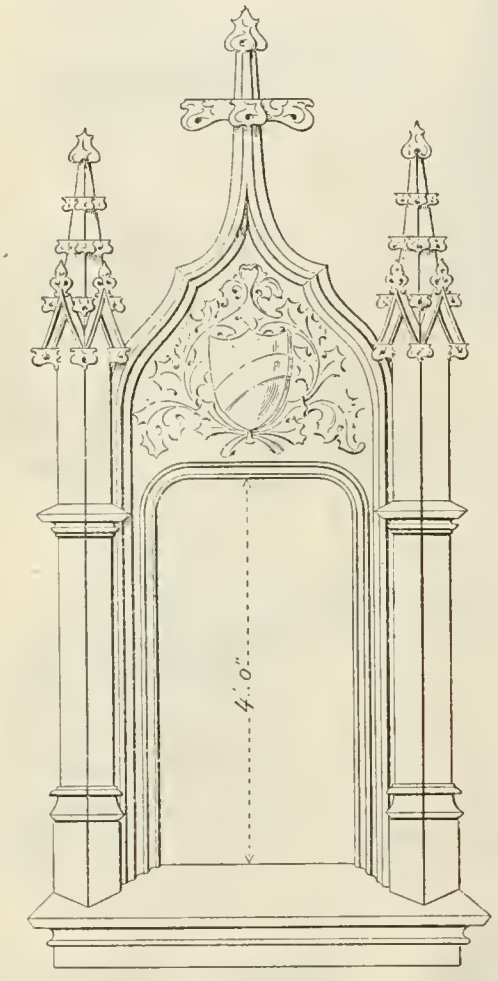


Fig. 1.—Front Elevation of Dormer Window

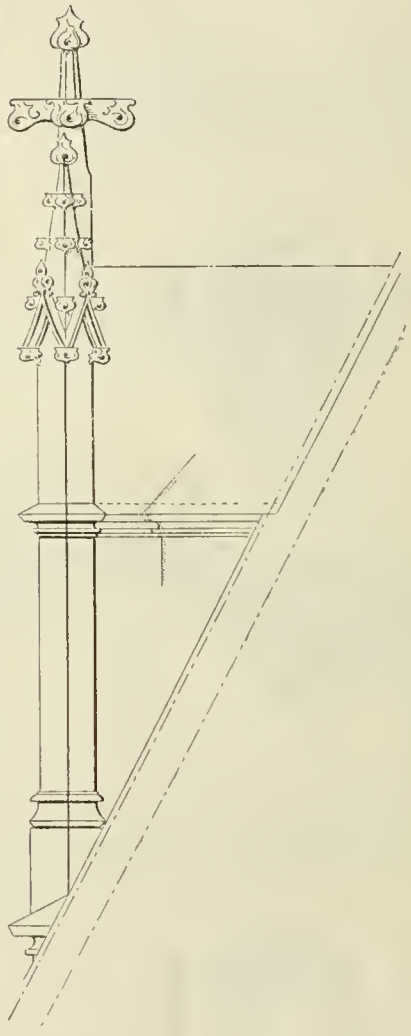

Fig. 2.—Side Elevation.

dormer window made of 20-ounce cold rolled copper. The round corners shown at the upper part of the window openings, likewise the moldings at the top of the dormer, were entirely hammered by hand, raising or stretching the blanks as was required. The center ornament was stamped with background complete and riveted to the flange made on the curved moldings for that purpose and soldered on the inside. The center finial was stamped in parts, soldered together and attached to the hammered work below the crockets. The side pilasters were formed in separate parts, riveted to the copper work, as shown in front elevation, after which the pinnacles were placed in position. In constructing the pinnacles the square pyramids shown on each side in front elevation were first formed and then attached to the square shafts below, after which the small crockets and gables were soldered in their proper positions. The return molding, shown in the side elevation, Fig. 2, was soldered to the

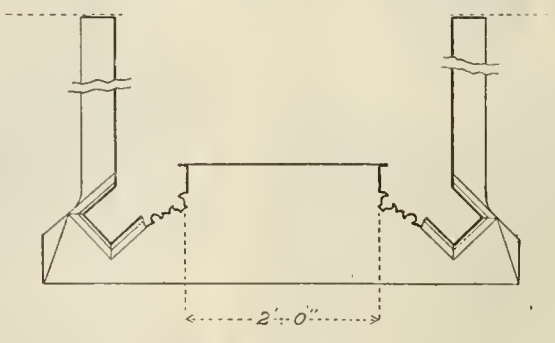

Fig. 3.—Plan.

ELABORATE SHEET COPPER WORK.

is covered with slate. All the joints and seams, where possible, were soldered on the inside, so as to show a clean surface. All other work which had to be sol- parts were bronzed with copper bronze of the same shade as the sheet copper, which gives a clean finish. The hight of the finished dormer measures 10 feet

9 inches from bottom of sill to top of finial. This copper work was made in the shop of J. Foerster & Son, 806 Fifth street, New York.

A Chat on Copper Roofing.

In a conversation with J. Flanagen, 396 Fourth avenue, New York, he made the following observations on copper roofing:

The roofing and, in fact, all of the sheet iron and copper work of the new Criminal Court Building, New York, was put on by my men. The steep part of the roof was covered with copper Spanish tile, and the flat portion with 18-ounce sheet copper, put on in the ordinary manner, one sheet at a time, like tin roofing. The sheathing on which it was laid was well seasoned, dry 1⅛ inch planking supported by rafters that were sufficiently close together to make the roof firm, so that when the seams were beaten down with a mallet the whole building did not shake. The sheets were 14 x 20 in size, notched and edged in a regular roofing brake.

They were laid with cleats, the nails used being of the drive screw character, tinned. In soldering about 8 pounds of solder were used to the square. Such a roof is worth about 25 cents a square foot, and when put on in this way it is not only calculated to last an indefinite time, but in case it should be taken off for any reason the old roof will bring enough money when sold to a junk dealer to pay for a new tin roof. Another advantage is that it never needs painting. The roof has now been on the building for over a year, and no difficulty has been experienced from expansion and contraction. The roof of the City Hall was put on about 50 years ago, and was put on in the standing seam style, and shows to-day in perfectly good condition, and has never had a coat of paint. If the people knew the advantages that follow the use of copper for roofing, it is probable that more would be used. Its use for covering public buildings is growing, and as architects and builders become more experienced with it, those who can afford to pay the price will specify it to be used on buildings in which they invest their money.

FLASHINGS.

J. Flanagen, 396 Fourth avenue, New York, is furnishing the galvanized iron work and copper front for the annex to Grammar School No. 25, at 104th street and Amsterdam avenue. The gothic windows at the top of the building will be covered with slate, while the roof will be of Meurer triple coated IX tin.

Schwing & Co., 190 Ferry street, Newark, N. J., make a specialty of architectural sheet iron work. They are making 24 large skylights for the Celluloid Company of Newark and furnishing skylights, sheet metal front and cornices for the new opera house at Elizabeth, N. J. They are making a new cornice for the store of A. F. Leicht, at Jersey City, N. J., and cornices and skylights for a school at Franklin, N. J.

"Total Eclipse" is the curious title of a little pamphlet of which we have recently received a copy. Further inspection shows that it relates to the Eclipse gutter beading and forming machine made by the Eclipse Machine Company of Troy, N. Y. Illustrations are given of the machine and testimonial letters are presented.

The Phœnix Plumbing Company, Phœnix, Ariz., have completed a large sheet iron front for the new business block being erected by Dr. Mahoney, adjoining the post office.

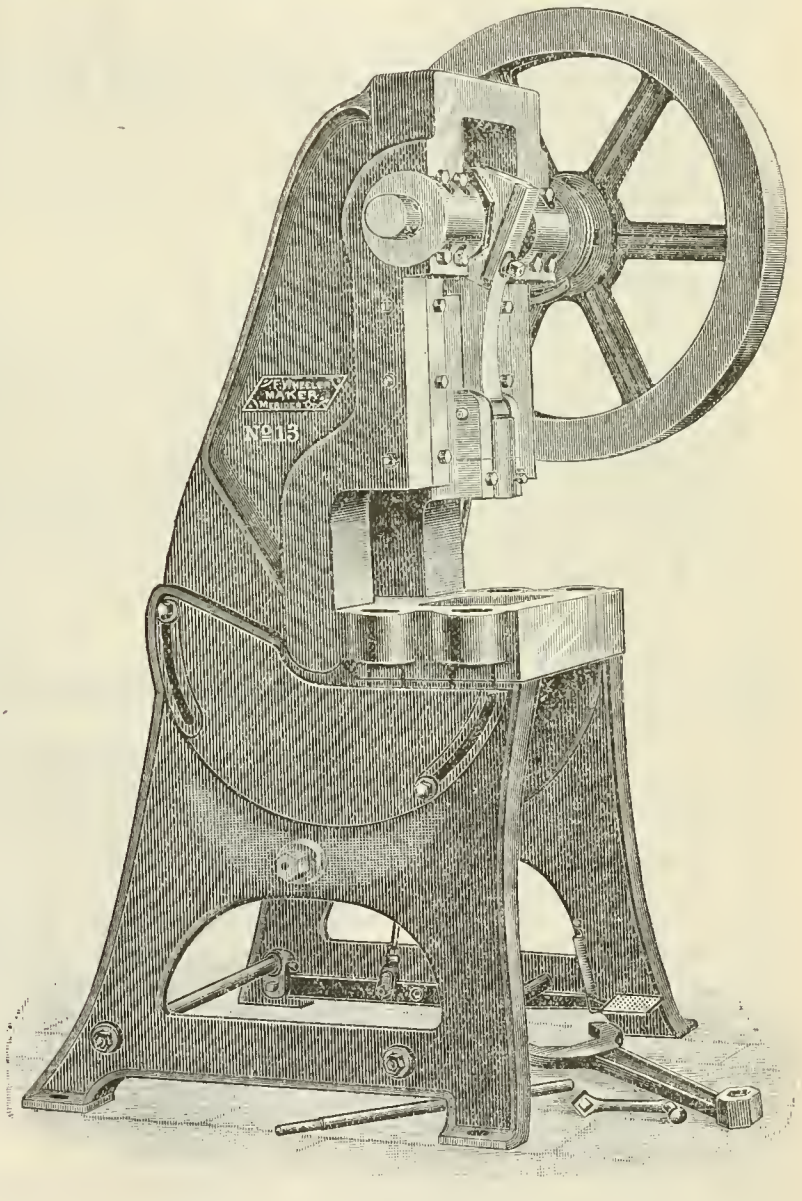
J. C. McFarland, 2511 to 2519 State street, Chicago, is to furnish the copper cornice, gutters, flashings, terra cotta cresting and 110 squares of Spanish tile roof for the residence of Philip Armour, Jr., Michigan avenue and Forty-seventh street.

The Wheeler Press.

This press, built by Frank Wheeler of Meriden, Conn., is provided with an incline adjustment, consisting of a sliding box placed on top of the pitman. The solid pitman is so arranged that all the strain and pressure come upon solid metal, the lower end of the pitman being seated in the solid metal of the slide or gate, and not resting upon a screw or pin. For adjusting the punch to the die it is simply necessary to turn a screw after loosening the clamping nut, when the box can be moved up or down the incline to the desired position.

The pressure at the time when the press is doing its heaviest work is brought squarely upon the end of the pitman, thereby relieving the adjusting screw and clamping nut from all strain and obviating the tendency to slip or strip the thread of the screw.

The machine is provided with a double clutch, which makes two points of contact simultaneously on opposite sides of and in and near the center of the press shaft. This does away with the cramping and twisting tendencies usual in clutches where the contact is made at only one point. By means of an automatic brake the press is stopped gradually and easily, there being no jolt or jar. The grate is so constructed as to take up all wear automatically and is provided with a self oiling device. The machine has a positive "stop up," which is simple in construction and automatic in operation.



The Wheeler Press.

Canadian trade returns for the nine months ended March 31 show a slight decrease in both exports and imports. Exports were $89,506,306, or $41,000 less than in the corresponding period of last year, while the imports were $86,197 918, or $825,022 less. The duty collected for the period exhibits a falling off of $500,000.

PLUMBING and GAS FITTING.

The Chicago Plumbers' Settlement.

The new agreement made by the Chicago master plumbers and the journeymen on the 25th ult. is practically the same as that which was in force for the previous two years. The rate of wages is to remain at $3.75 a day of eight hours. From June 15 to September 15 the hours of work Saturday will be from 8 a.m. to 12 m., for which the journeymen are to receive $2.25. Overtime is to be computed at one and one-half times the rate for regular time, except Sundays, national holidays and time after midnight, which is to be counted at twice regular time. Journeymen working outside the city will have their board and railroad tickets furnished, and when traveling at night will have a sleeper furnished when the distance is more than 100 miles. Time when traveling is to be computed as if the men were at work, except that single time will be allowed for Sunday and no charge made for traveling at night. The journeymen's association agrees to use all honorable means to make good any careless or incompetent work of any of its members.

All differences arising between employers and employees are to be settled by a committee of arbitration selected from the members of the association. No strike can be declared without first submitting the grievance to arbitration. Rules governing apprentices will be adopted by a joint committee selected from the two associations, which shall make its report before September 15, 1895. The new agreement is to remain in force until March 1, 1896.

Venetian Bath with Patent Folding Needle Bath.

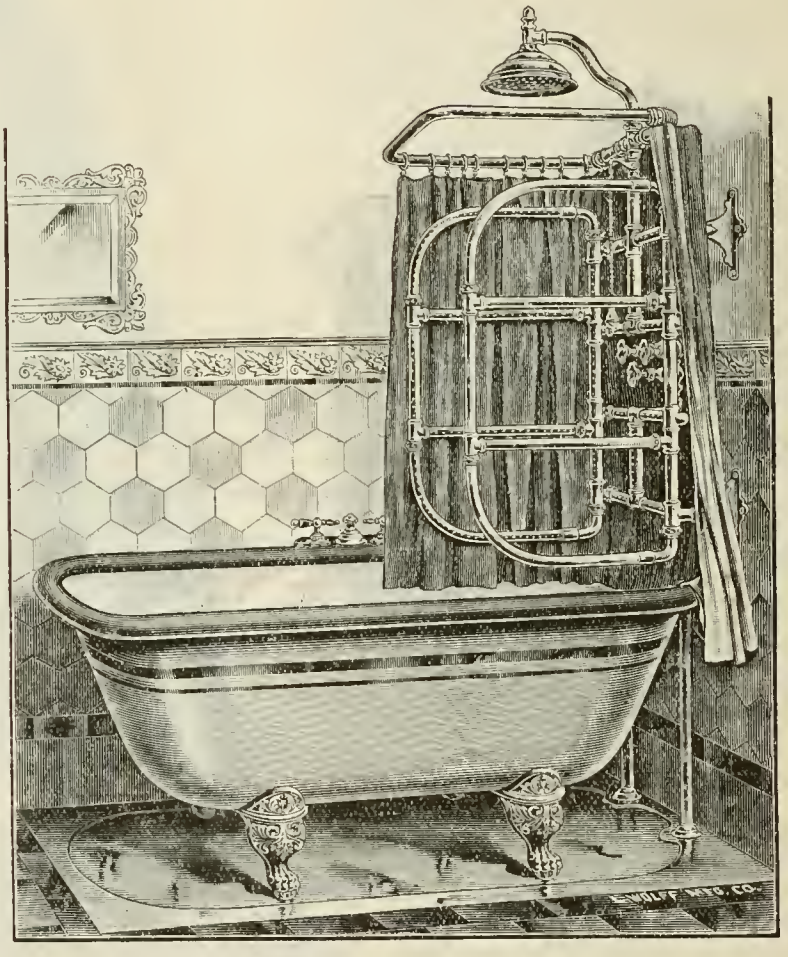
The L. Wolff Mfg. Company, 93 West Lake street, Chicago, have brought out a new and decidedly original arrangement for the bathroom, which is illustrated in the accompanying cut. The tub is highly ornate, being a white enameled iron Venetian bath, finished in zinc, white outside with two gold bands, all polished and nickel plated, Fuller double faucet with connection for bottom supply, supply pipes to floor, all polished and nickel plated Ideal waste, a 3 x 2-inch cherry roll rim rabbeted to fit the flange of the tub, legs of ornamental design, 19 inches inside depth, 26 inches inside width and in two lengths, 5 feet 5 inches and 5 feet 11 inches outside measurement. The tub is fitted with a needle and shower bath, so constructed that it can be folded together when not in use, and is adapted equally well for Turkish baths, athletic clubs, &c., or the private bathroom. When folded it requires but 9 inches of space, this being the projection from the wall, and therefore it can be used in the smallest bathroom.

When placed over a bathtub and folded it leaves the tub entirely free for the bather's use. This needle bath is strongly made and carefully put together and is of handsome design. The shower and needle bath or the bathtub fixtures can be operated separately or together as desired, each being governed by its own valves.

The Smoke Test.

The following is an account of a smoke test made by Boyd & Schnaier, 347 Columbus avenue, New York, in the residence of R. A. Myres, 59 East Ninety-second street, and which, in view of the attention now being attracted by this kind of test, will be read with interest. The building in which the test was made was a dwelling of four stories and a basement in which the plumbing system has been in use for seven or eight years. There were three soil pipes coming through the roof, and the back air pipes from the fixtures were connected with these pipes above the highest fixtures and below the roof. One was at the back of the house and the other two at the sides of the house, nearly opposite, near the center.

The test was made from the roof, as the fresh air inlet at the street was inaccessible. A hose led from the machine used for the test to the soil pipe, where it came through the roof and entered the open end, and the space around the hose was closed by packing with waste or oakum. The smoke chamber of the machine was charged with tarred paper, such as is used often in roofing, and in order to make a dense and penetrating smoke some waste that had been saturated with turpentine and also some sulphur was put in. The charge was lighted at the bottom, the chamber covered and the machine operated, which pumped in a continual current of air at the base of the charge which generated the smoke and forced it out through the hose into the plumbing system. As the smoke was driven down through this line of pipe it finally reached the horizontal pipe in the cellar and from the branches into it finally made its appearance through each of the other two openings on the roof. The other openings were then closed with a wad of oakum and the machine operated gently while a search was made through the house for leaks.



Venetian Bath with Patent Folding Needle Bath.

The first discovered was in an old fashioned bell trap placed in the cellar floor to carry off the water that might be used when the cellar was washed. The cloud of smoke which came from this opening showed that the seal of this trap was broken, and on lifting off the cover and stopping the opening with a wad of paper, the trap was

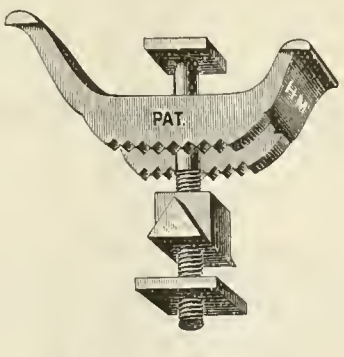
found to be perfectly dry and filled with dust, clearly showing that for over a year this trap has been ineffective and that sewer gases could freely enter the house. The next leak found was on the kitchen floor, in the back air pipe from the trap under the sink where it passed through the wainscoting. A nail had been driven in it and made a hole ⅛ inch in diameter through which gas could escape.

On the floor above, the back air pipe from the lavatory trap in one of the chambers was connected with a vertical branch joint, and in wiping this joint the plumber had not been careful to see that the under side was tinned. In consequence a tight joint had not been made, and had it been used for water the leak would have been readily seen. In appearance this joint was as good as any on the job, but the smell of smoke that filled the chamber and the smoke that puffed from the leak showed clearly where it was located and every movement of the machine on the roof was shown by a little puff of smoke through the opening in the joint. Another leak was found in the water closet on the third floor. This evidently was caused by the soil pipe settling. The leak, instead of being the usual vertical split in the pipe, caused by careless calking, was due to a break extending around it, just where the pipe proper connects with the hub. Though a candle was used to examine the crack, it was so fine that it was difficult to see it, yet the smoke puffed from it promptly with every stroke of the machine on the roof. The cause of some of the leaks in this section of the city in old houses may be due to the fact that rock underlies the ground, and in digging the cellars for new buildings the rock is blasted out, jarring the whole nighborhood. While this test was being made a severe shock was felt in the building as the result of a blast going off about half a block away.

THE STAR COUPLER COMPANY, St. Louis, Mo., report a heavy demand for their Star water back and boiler couplers. They are at present running night and day in their efforts to keep abreast of their orders. They recently received an interesting letter from Geo. M. Clark & Co., Chicago, Ill., who subjected the coupler to 250 pounds test and found it worked perfectly, and as the result of this test they are duplicating their orders. The Star Coupler Company received the contract for the new Planters' House, St. Louis. The couplers were specified and will be used for connecting 250 gas grates and logs. The Dawson Bros. grates of Chicago, Ill., will be used.

The Mueller Basin Clamp.

The H. Mueller Mfg. Company of Decatur, Ill., are manufacturing a basin clamp of newly patented design, which is herewith illustrated. This clamp is adjustable, so that it will fit any thickness of flange on the bowl. The main body of the clamp has a long slot in the center through which the bolt passes, thereby allowing the longest possible range of adjustment lengthwise. For this reason it is not necessary that the bolt be placed at any certain distance from the flange of the bowl. The washer, being wedge shaped, will always adjust itself to form a square bearing for the nut. That part of the clamp which comes in contact with the washer is notched, so that the washer holds it firmly in place, thereby preventing it from slipping. All the goods manufactured by this company are branded "H. M.," and they will warrant anything they make.

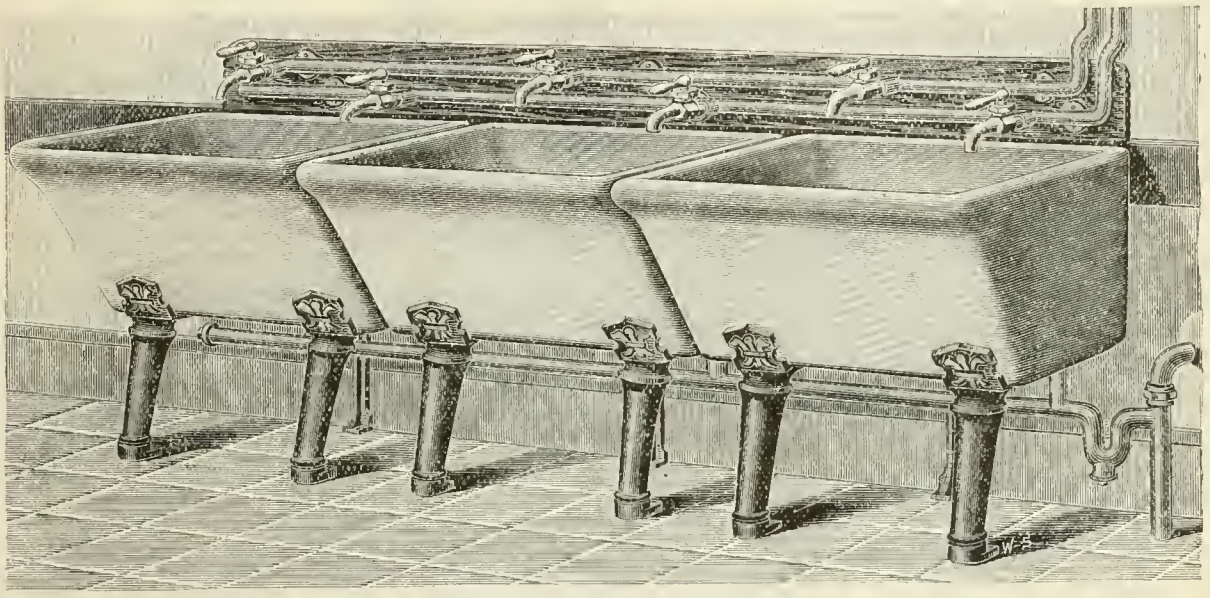


The Mueller Basin Clamp.

ROURKE & MCDONOUGH have retired from the plumbing business, at Knoxville, Tenn., and Kirk & Stout, two of their former employees, will succeed them. The firm of Rourke & McDonough, so long known in the plumbing business, will henceforth give their whole attention to the heating of buildings and to handling plumbing supplies.

Yorkshire Brown Glazed Laundry Tubs.

We show in the accompanying illustration the Yorkshire Brown Glazed Laundry Tubs, manufactured by Evens & Howard, St. Louis, Mo. A special feature of these tubs is that each one is made of a single piece of earthenware, hardened at a very high heat, and covered in and outside with a strong glaze of a rich dark brown color, which is said to be absolutely impervious to water, grease or acids. The corners are rounded, thus giving every facility for cleaning. They are finished with roll rims and supported by cast iron standards, as shown. The length, outside dimensions, of standard size, is 27½ inches; width, 22 inches; hight, 16 inches, and thickness, 1½ inches.



Yorkshire Brown Glazed Laundry Tubs.

TRAPS AND VENTS.

THE SHOW WINDOW of O'Brien & Lavelle, 162 East Twenty eighth street, New York, is arranged to attract the attention of all who pass. It shows on one side a lavatory fitted up with nickel pipes and trap, having a yellow sienna marble slab and a bowl decorated with flowers and gilt. On the other side they show a gilt decorated square top syphon jet water closet, connected with flush tank. In the center space is a porcelain lined cast iron bath, which is also decorated in gilt, resting on a Persian rug. The bottom of the window is covered with tile and a good idea is given of a model bathroom.

GEORGE M. FOSTER & CO. are a new house at 345 East Fifty-ninth street, New York, who make a specialty of plumbers' marble work, both for fixtures and wainscoting and flooring bathrooms or apartments.

THE L. WOLFF MFG. COMPANY, 93 West Lake street, Chicago, have just brought out their Supplement No. 1 to advance Catalogue B, in which they illustrate and describe Wolff's enameled iron baths. This is a 40-page cata-

logue, large quarto, filled with very choice engravings and exquisitely printed. A very great variety of enameled iron baths is shown, from rigidly plain ones to others of the most artistic finish in shape and decorations. Illustrations in colors are given in the catalogue of hand painted borders, which are used in decorating the more expensive bathtubs. The company are now producing an enamel which has proved very satisfactory. It makes a beautiful finish and is of a rich pure color. They enamel all their own goods. In addition to baths, the catalogue contains illustrations of Wolff's patent folding needle and shower baths; also bathroom fittings, such as nickel plated and brass towel racks, soap cup, tumbler holders, sponge holders, &c. Samples of the company's enameled goods and other plumbing specialties are on exhibition at their showrooms at 91 Dearborn street, Chicago; 1533 Blake street, Denver, and 11 North Washington avenue, Minneapolis. The last named branch has but recently been established, and is in charge of F. J. McArdle.

N. MEREDITH, Johnstown, N. Y., will move his plumbing shop from Church street to the store on South Perry street.

S. & A. CLARK, plumbers, are now in their new place of business at the corner of North Fourth and Prospect avenues, Mt. Vernon, N. Y.

CHAS. F. GEISSELE, 224 Ferry street, Newark, N. J., is one of the busy plumbers of that city.

AT A MEETING of the Master Plumbers' Association of Pittsburgh, held in the Builders' Exchange in that city on Tuesday, May 1, the following delegates were selected to attend the National Convention of the Master Plumbers' Association of the United States, to be held in Detroit, Mich., in June: R. J. Bradshaw, J. O. McGinniss, F. J. Gray, Joseph Rice, Frank McKnight, A. R. Tate, J. J. Cowling; alternates, William Collins, Samuel Harr, John Madde, Leo McShane.

DEMOCK, FINK & Co. are fitting up their showroom at 80 John street, New York, in a similar style to their showroom at 214 and 216 East 125th street. A row of water closets are set on Italian marble slabs against a wainscoting of Italian marble, with their flush tanks and nickel plated flush pipes connected with them all ready for use. The Primrose syphon jet has the place of honor, and is a handsomely decorated closet. The Orient and Melrose are front and back washout closets, representing the best productions in their line. These are followed by other closets of less pretensions in decoration. They also show a fine line of lavatories, the slabs being of Numidian, Verona, Italian and Knoxville marble and one handsome onyx. They are fitted with different styles of nickel plated fixtures and bowls in different styles of ornamentation. A handsome porcelain enameled bath is placed in the center of the floor, and white porcelain and brown Yorkshire laundry tubs are also conspicuously displayed.

THE INSTANTANEOUS WATER HEATING COMPANY, Chicago, have established an Eastern branch at 838 Broadway, New York, where they will carry a full line of Douglas and Acme heaters for heating water for domestic purposes. S. Bernstein, manager of the company in Chicago, has been in New York for the past month arranging for the Eastern branch. With him is E. Brownhill, who has been with the company in Chicago and who will be the Eastern manager.

G. M. SINCLAIR, plumbing inspector, Hoboken, N. J., reports a general improvement in the quality of plumbing work as conducted under the regulations of the sanitary code. He feels certain when the craft becomes thoroughly acquainted with the new condition of things and the rules more strictly adhered to, great good will result.

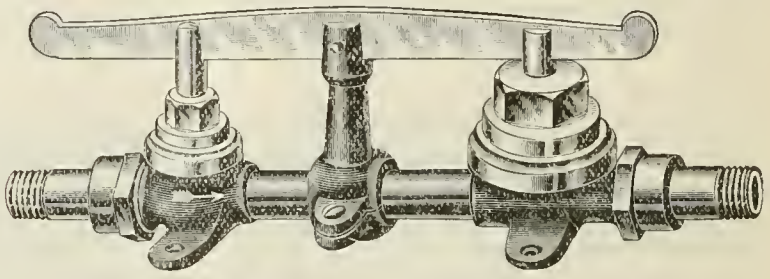
JOHN C. C. BOHLMAN & Co. have fitted up a building in the rear of the former's residence and fronting on Tyler street, Pittsfield, Mass., for their plumbing establishment, and are now ready for business.

ALCOCK PLUMBING COMPANY have been incorporated at Chicago, with a capital stock of $12.000. The incorporators are Joseph R. Alcock, Charles Alcock and W. J. Alcock.

SOME DISCUSSION is going on in the local papers of Hoboken, N. J., in reference to a new sanitary code that is being enforced. With the plumbers generally it is popular, as it is of the progressive character and modeled after the plumbing laws of New York City. On the other hand, as it makes some radical changes in the plumbing practice and requires a more expensive system than formerly, it is being sharply criticised.

Bennett's Water Pressure Regulator.

We show in the accompanying illustrations a general and a sectional view of Bennett's water pressure regulator, put on the market by the Bailey-Farrell Mfg. Company, Pittsburgh, Pa. Fig. 1 is a general view of the device, while Fig. 2 is a sectional view, showing its internal construction and its method of operation. The purpose of this device is to deliver water automatically from the street mains into the service pipes at any desired pressure, irrespective of the variations of the water pressure in the street mains. The regulator, it is said, responds quickly to the slightest fluctuation of initial pressure and maintains a constant, uniform pressure on the house service. It is placed on any convenient point on the water pipe supplying the house with the inlet end D, Fig. 2, at the street main. The water supply enters through D, K and E and exercises its pressure on the enlarged diaphragm J, communicating the water pressure from the house service pipe I through the scale beam A to shut off the pressure at the diaphragm K. The amount of pressure to be carried in the house service pipe at I can be adjusted by moving the fulcrum F to the right or left as desired. The device is spoken of as a simple, sensitive automatic regulator, having no wearing out parts except the rubber diaphragms J and K, which can be replaced as easily as an ordinary compression bibb can be repaired.



Bennett's Water Pressure Regulator.—Fig. 1.—General View of the Regulator.

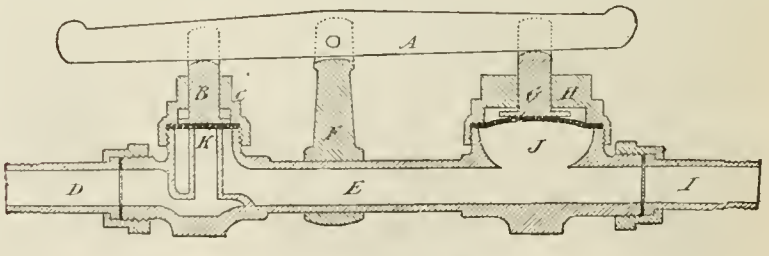


Fig. 2.—Sectional View.

The British Government allotment for reserve merchant cruisers, to be held at the government's disposal in case of war, is announced to be $162,500 for the present fiscal year. The companies subsidized are the Cunard for the "Campania" and "Etruria," the P. & O. for four large vessels of between 6000 and 7000 tons, the White Star for the "Teutonic" and "Majestic," and the Canadian Pacific for their three 6000-ton steamers, the "Empress of Japan," "Empress of China," and "Empress of India." In addition, the Cunard Company hold in readiness three vessels, the "Umbria," "Aurania," and "Servia," the White Star, the "Germanic," "Britannic" and "Adriatic" and the P. & O., 10 vessels of about 5000 tons each. Thus the Government pays for 12 steamers and gets 16 free.

The London *Economist* finds that a decided revival of business has begun in England. Although prices have declined 5 per cent., the values of exports are about on a par with those of last year, which they exceed in amount. Labor is more fully employed than at this season a year ago, the number of manufacturing establishments in operation is increasing, and reports from the chief industrial centers indicate a more hopeful feeling. Railway receipts, too, for the first quarter of 1894 were over 3 per cent. larger than those of the March quarter in 1893.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

THE J. F. PEASE FURNACE COMPANY, Syracuse, N. Y., have been awarded the contract for the heating plant and the water closets and urinals for the Franklin School Building, at Bethlehem. The Demorest system of water closets, manufactured by the J. L. Mott Iron Works of New York, will be used.

JOHN A. SCOLLAY, 74 and 76 Myrtle avenue, Brooklyn, N. Y., has been awarded the contract for installing a hot water heating plant in the residence of J. H. O'Neil, Surrogate of Hudson County, at Jersey City, N. J.

THE A. HARVEY'S SONS MFG. COMPANY, Detroit, Mich., have been awarded a contract amounting to about $150,000 by the Economy Light, Heat & Power Company of Scranton, Pa., for the erection of a central plant and laying mains through that city for furnishing heat and power to customers. It is to be in operation by September 15.

C. H. GREEN, plumber, on Wyandotte street, South Bethlehem, Pa., has received the contract for doing all the sanitary and plumbing work at the new residence of Instructor Biggin of Lehigh University, on Broad street, West Bethlehem.

MRS. COLEMAN-STUCKERT is to build a co-operative house in Hyde Park, Ill., which will cover an entire block and cost $200,000. It will have electric light, steam heat and a system of plumbing.

MCDONALD & Co., 296 Sixth avenue, New York, are engaged in installing the plumbing system in the new annex to the Buckingham Hotel, Fifth avenue, New York. They are also about finishing the work in the Home Life Insurance Building and the Bowery Savings Bank, New York.

ARCHITECTS BROMPTON & LAWSON, Chicago, have prepared plans for a three-story apartment building, to be erected at 1322 Sheffield avenue for A. Allender. Galvanized iron work front; heating not decided.

ARCHITECT W. J. VAN KUREN, Chicago, has designed for J. E. Decker a three-story apartment house, to be erected on Park avenue, near Grove street, in Austin, Ill. Steam heat is to be used.

ARCHITECTS KIRKPATRICK & COLLINS, Chicago, have planned for George Blume, at Lawndale avenue, near Eighteenth street, a two-story flat building, to be heated by steam; for Mrs. H. F. Wallace, at 1181 Wilcox avenue, a two-story residence, to be heated with a furnace; for J. D. Rowe, at Wilcox avenue and Forty-fourth street, two cottages, to be heated by furnaces.

ARCHITECT F. NEWELL, Chicago, has prepared plans for the People's Institute, to be built on West Van Buren and Leavitt streets, with pressed brick and terra cotta front, tile and copper roof, cement and metal work, &c.

ARCHITECT L. G. HALLBERG, Chicago, has designed for George A. Stevens ten two-story houses, to be built at Clifton and Greenwood avenues. Warm air furnaces are to be used for heating.

ARCHITECT JULIUS HUBER, Chicago, has designed for Charles Steinbrecher a five-story apartment house, to be erected at Milwaukee avenue and Union street. It will be heated by steam and will be equipped with all modern improvements.

ARCHITECTS WORTHMAN & NEEBE, Chicago, have drawn plans for a three-story flat building, to be erected at Twelfth street, near Ogden avenue, for Mrs. Catherine Armstrong, to have all modern improvements, including galvanized iron work.

SMITH & WEBSTER, 15 to 21 North Clinton street, Chicago, are to furnish 50 No. 9 S. & W. porcelain baths, lavatories, &c., for the Holmes Hotel, Minneapolis. W. W. Sykes & Co. of the latter city do the plumbing work.

FOSTER & GLIDDEN, agents for the Farquhar Heating Company, 53 Dearborn street, Chicago, have the contract for placing a No. 28 Panama warm air heater in the residence of J. C. Triger, Blue Island, Ill.

THE BAKER & SMITH COMPANY, 193 to 197 Van Buren street, Chicago, are to furnish two tubular boilers and the necessary radiation for steam heating in the Kentucky School of Medicine, Louisville, Ky.

ARCHITECTS STILES & STONE, Chicago, have designed for J. Marshall a double residence, to be built at Fifty-fourth street, between Jefferson and Washington avenues, to be heated by hot water. The same architects have planned for Nicholas Hunt a three-story apartment house to be built on Monroe avenue, between Fifty-seventh and Fifty-eighth streets.

BLAKE & WILLIAMS, 197 Wooster street, New York, are engaged in installing a heating plant in a school at Forty-sixth street and Sixth avenue. The contract amounts to $26,000, and will include a combination of the blower and exhaust systems with both direct and indirect radiation. They are also installing a heating plant in the addition to the New York City Building for the Insane, at Central Islip, L. I. This contract amounts to $36,000, and a feature of this system is that the extreme radiation is placed over half a mile from the boiler. The water is returned from the system to a tank and is pumped into the boiler. They are also engaged in installing a heating plant in the new government building at West Point, N. Y. This contract amounts to $30,000.

F. E. GRIMSHAW, East Hampton, L. I., has the contract for the plumbing in a new residence to be erected on the Dunes near the ocean by H. A. James of New York City. The water is brought across from Georgica Pond more than 1000 feet by an air motor mounted on a steel tower 40 feet high which operates a pump. O. H. Northrop, well known in western Connecticut, has the work in charge.

ALBERT A. CRVER & Co., 85 Centre street, New York, has been awarded the contract by Capt. Thomas McManus for heating an apartment house on Fifth avenue, in which a No. 320 ten-section steam heater will be used, and a No. 55 Victor steam heater will be used in an apartment house he is erecting at the corner of 115th street and Fifth avenue for the same contractor. They will also install a No. 55 Victor steam heater in the apartment house being erected by Rudolph Guggenheimer, at 101st street, New York.

G. M. SINCLAIR, 106 Fourth street, Hoboken, N. J., is doing the plumbing, heating and electric lighting in the new Fire Department headquarters of that town. A conspicuous feature of the plumbing is the nickel plated piping and faucets, making a very attractive appearance. The heating is by hot water, a Perfect boiler, made by the American Boiler Company, being employed for the purpose. The contract amounts to $2700.

DAVIS, WRIGHT & Co. of Keene, N. H., have the contract for placing a No. 55 Victor steam heater in the dwelling owned by George O. Hayward of Keene, N. H. They have also the contract for heating the block remodeled and owned by F. H. Wright & Co., in which they will use a No. 320 seven-section Richmond heater.

E. H. RANDALL & Co., Concord, N. H., have a number of heating contracts on hand, among which is the contract to heat the house owned by L. R. Wood of Bradford, Vt., in which they will place a No. 418 Richmond steam heater.

SANDS & REGAN, 54 Fifth avenue, Chicago, have the contract for plumbing, sewerage and gas fitting in the residence of A. Leonard, 6026 Wharton avenue.

THE S. WILKS MFG. COMPANY, 113 to 123 Clinton street, Chicago, have received orders for four large water heaters for the new officers' quarters at Fort Riley, Kan.; four 16 x 36 inch self feeding water heaters with automatic damper regulators for the Plattsburg Barracks, Plattsburg, N. Y.; one large water heater and tank for the Y. M. C. A., Cumberland, Md., and one water heater for the Y. M. C. A. new building, Memphis, Tenn. Since the settlement of the local strike city orders are coming in freely.

SCRAP.

THE LOCKOUT in a number of Welsh tin plate works against the 36 box rule still continues, without any sign of yielding on the part either of the employers or the employed.

THE STATISTICAL STATEMENT of imports and exports issued by the Treasury Department for the month of March, 1894, illustrates clearly the marked falling off in tin plate receipts during the present fiscal year. Under the head of "Tin plates, terne plates, and tagger's tin," the imports for the month of March are shown to have been 39,968,992 pounds of the value of $1,055,124, against 55,084.059 and $1.525,878 respectively in March of last year. For the nine months ended March 31 in each year the quantities imported were as follows: 1894, 333,643,743 pounds; 1893, 420,279,313 pounds, and the values were for 1894, $8,938,428; for 1893, $11,830,401.

IN A HANDSOME industrial edition, lately issued, the *Keystone Gazette* of Bellefonte, Pa., suggests that the large nail works of that town, which are for sale, would be admirably adapted for a tin plate works.

N. & G. TAYLOR COMPANY, Philadelphia, have just supplied their Old Style brand of extra heavy coated roofing tin tor covering the State Library and Executive building at Harrisburg, Pa. The same brand is also used on the House of Representatives. Messrs. Taylor Company report an excellent and steady demand for all their product, and say their works in Philadelphia are fully employed not only on terne plate, but also on bright tin plate of all kinds.

STEAM AND HOT WATER.

Arrangement of Air Ducts.

BY HELIOS.

Fig. 1 shows indirect radiation with tile cold air duct under the cellar floor and with mixing valve and register in side wall. The cold air pipe is made of sewer pipe and is carried under the cellar floor out through the wall and up to grade, same as shown in a previous article. Great care must be taken in laying this pipe to have all the joints cemented perfectly water and air tight. All the cold air pipe above the cellar floor is galvanized iron.

Fig. 2 shows indirect radiation with tile cold air duct under the cellar floor, without mixing valve, with register in the floor.

Fig. 3 shows arrangement of indirect radiation taking the air from the room that the hot air is discharged into. This arrangement is used in basement houses where the room is on the same level with the boiler and the customer does not want to place a coil or radiator on the side wall of the room that is to be warmed.

Fig. 4 shows arrangement of indirect radiation the same as in Fig. 3, with cold air supply taken from outside the building, having the cold air pipe under the basement floor.

Fig. 5 shows side elevation of indirect radiation, with hot and cold air connections, mixing valve and cold air duct and hot air pipes in the wall of the building. This arrangement is used in schools or other large buildings where there are large numbers of indirect radiators supplied from one cold air duct. The cold air duct is built of brick, the wall of the building being used for one side of the duct.

Fig. 6 shows elevation of indirect

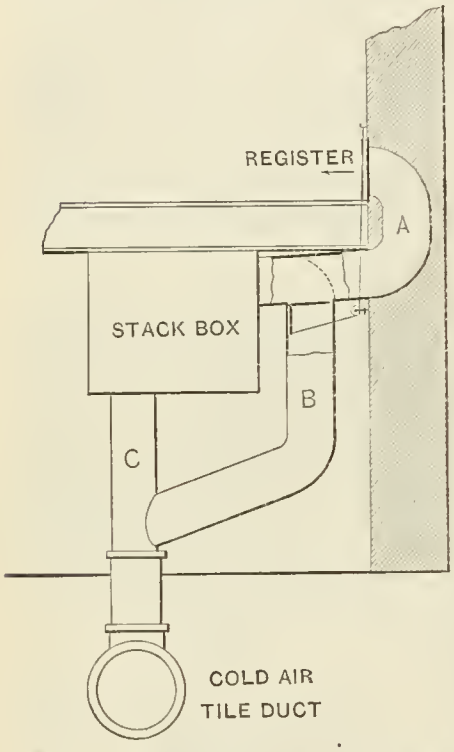

Fig. 1.—Indirect Radiator with Side Wall Register.

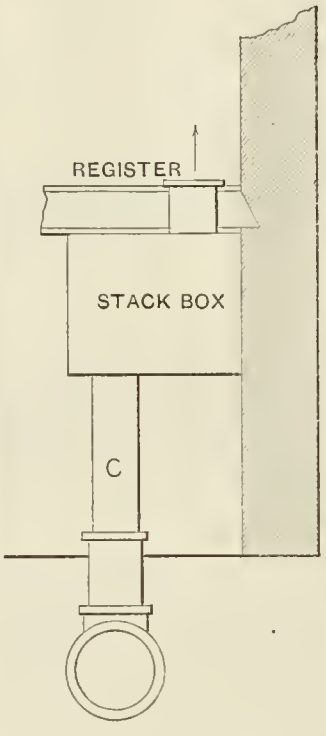

Fig. 2.—Indirect Radiator with Floor Register.

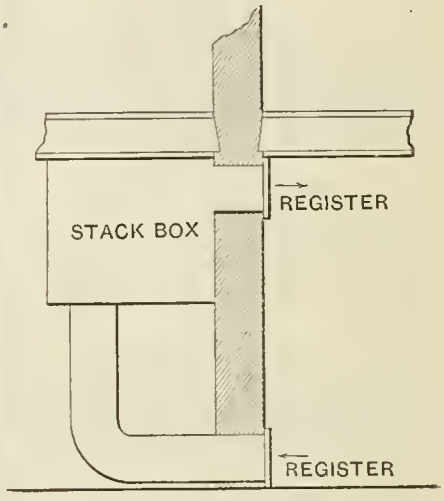

Fig. 3.—Indirect Radiator Circulating Air in Room.

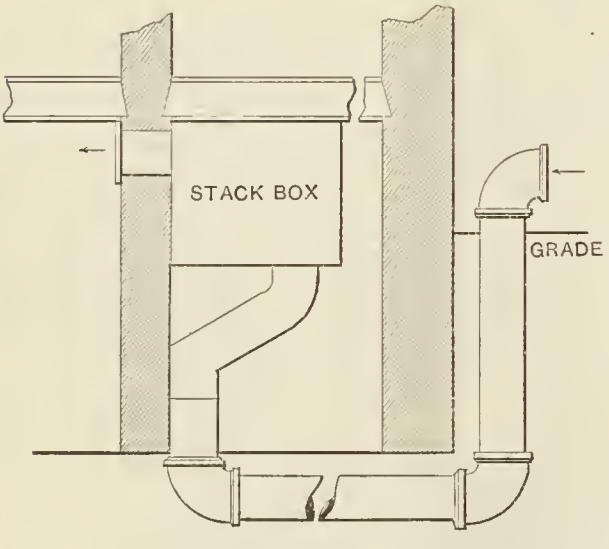

Fig. 4.—Indirect Radiator with Register Near Ceiling.

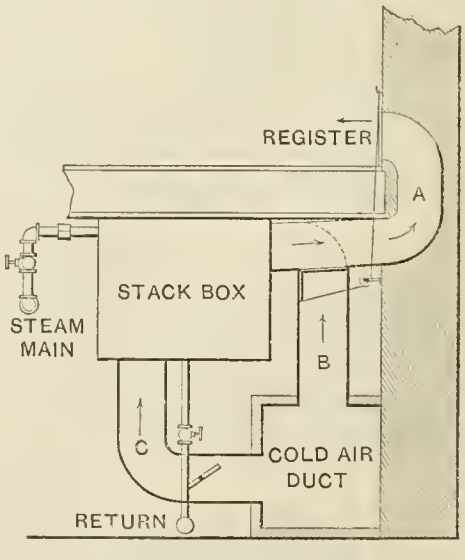

Fig. 5.—Indirect Radiator Used in Large Buildings.

ARRANGEMENT OF AIR DUCTS.

radiation connected to three floors of a building with the hot air pipes placed close together in the wall. The connecting pipes from the radiators to pipe in the wall and discharge of hot air into the rooms to be the same as shown in Fig. 5. C is the cold air pipe to radiators and B is the cold air pipe to mixing valve.

Fig. 7 is a plan of which the elevation is shown in Fig. 6. A, A, A are the hot air pipes in the walls to the first, second and third floors. B, B, B are the cold air pipes from cold air duct to mixing valve. C, C, C show where the cold air pipe is connected to the under side of stack box. The indirect radiators are placed out in the basement about 3 feet from the side wall. This is done to allow for connections to the mixing valves and for hot air pipe connections from the stack boxes. The chains from the mixing valves are run up in the hot air pipe to the room with which the radiation is connected.

Fig. 8 shows an arrangement of indirect radiation where the air is taken from the same room that is warmed. This arrangement is used in stores where there is no room for direct radiation and in halls of churches and schools for foot warmers. It is also very often used in dwellings in place of direct radiators.

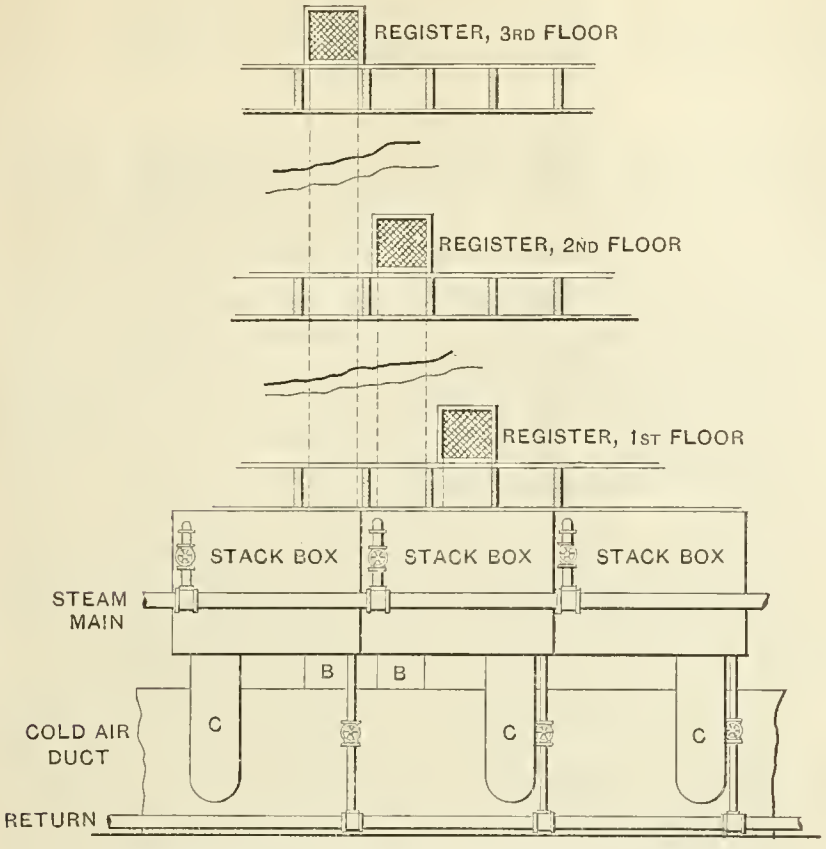

Fig. 6.—Elevation of Indirect Radiators and Registers.

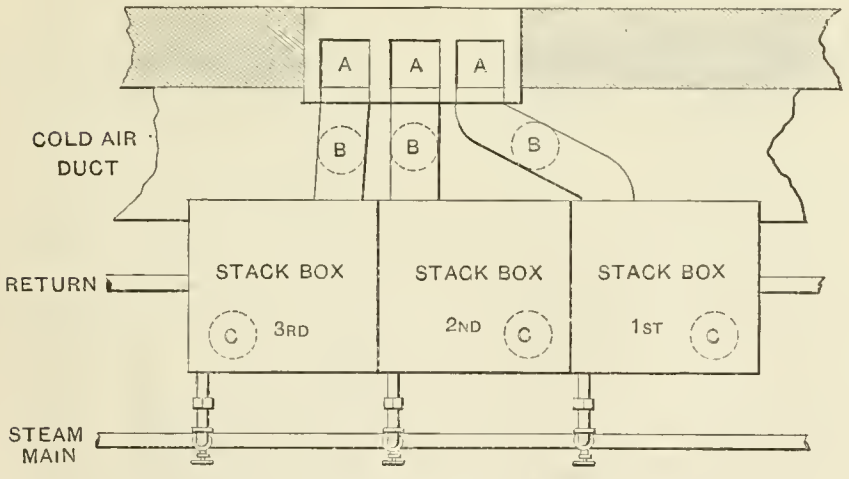

Fig. 7.—Plan of Indirect Radiators and Pipes.

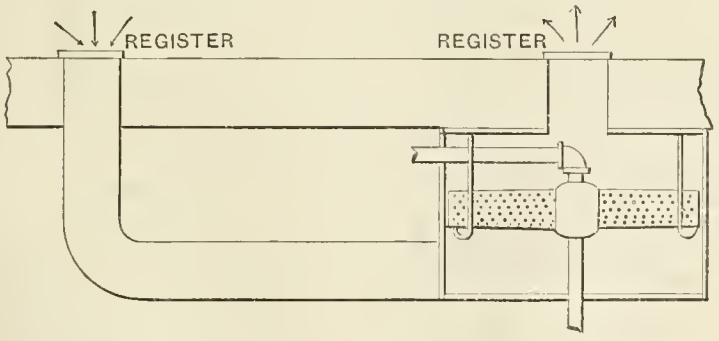

Fig. 8.—Indirect Radiator Drawing Air from Building.

ARRANGEMENT OF AIR DUCTS.

HEATING NOTES.

THE J. L. MOTT IRON WORKS, 84 Beekman street, New York, publish small illustrated circulars particularly devoted to the Sunray heaters. One of the circulars presents a general view of Mott's new Sunray steam heater, together with description and table of sizes and prices. The second circular gives a broken view of Mott's Sunray water heater, and also shows it in connection with a horizontal boiler.

THE A. A. GRIFFING IRON COMPANY, 34 Dearborn street, Chicago, have secured the Western agency of the Gurney hot water heaters, and will carry a full stock of them.

THE ALBANY STEAM TRAP COMPANY, Albany, N. Y., are doing a thriving business, making all kinds of specialties used in connection with steam power. The concern manufacture automatic steam pumps, valves, steam traps, governors, and every device required by users of steam.

HENRY HOUGHTELING, previously with the Gurney Hot Water Heater Company, has accepted the position of traveling salesman for the A. A. Griffing Iron Company, 34 Dearborn street, Chicago.

W. R. HARMOUNT, Detroit, Mich., whose name is familar to the steam and hot water heating trade, has just returned from Europe after a nine months' visit, which was spent in the joint pursuit of business and recreation. Mr. Harmount is much benefited by his outing and is well prepared to again enter into active business.

GEO. E. ADAMS & CO, Glens Falls, N. Y., are well pleased with the hot water heating plant which they placed in the Rockwell House in that city. It has been in every way a success.

W. B. TUFTS, 96 John street, New York, finds an increasing interest in the heating trades for iron pipes and fittings, of which he carries a varied line in addition to other steam and water supplies.

THE MAIN OFFICE of E. F. Keating has been removed to the warehouse and machine shop at 452 Water street, New York. Here he carries a line of everything required by the water or steam fitter, and is prepared to cut pipe to specification. An office is still maintained for the convenience of the trade at 75 John street.

RUBEL & BROTHERS have moved their factory from 209-211 South Clinton street to 114 116 East Lake street, Chicago, Ill.

STOVE TRADE NOTES.

THE TWENTY-THIRD Annual Stove Convention

WEDNESDAY.

The annual convention of the National Association of Stove Manufacturers met in the Banquet Hall of the Auditorium Hotel, Chicago, on Wednesday, the 2d inst.

Members Present.

The following is a list of members present at the meeting:

Barbour, Geo. H., the Michigan Stove Company, Detroit, Mich.
Bell, Joseph, Joseph Bell Stove & Range Company, Muncie, Ind.
Bennett, H. W., Indianapolis Stove Company, Indianapolis, Ind.
Boal, Stanhope, Favorite Stove & Range Company, Piqua, Ohio.
Bowditch, Edward, Rathbone, Sard & Co., Albany, N. Y.
Brasfield, G. M., Wooldridge Stove Company, Memphis, Tenn.
Brisland, James, Home Stove Works, Chicago.
Brooke, J., Floyd, Wells & Co., Royersford, Pa.
Burt, N. H., Great Western Stove Works, Leavenworth, Kan.
Buttorff, H. W., Phillips & Buttorff Mfg. Company, Nashville, Tenn.
Castle, C. H., Comstock Castle Stove Company, Quincy, Ill.
Collins, F. W., the Cortland-Howe Ventilating Stove Company, Cortland, N. Y.
Cribben, Henry, Cribben, Sexton & Co., Chicago, Ill.
Cribben, Wm. H., Cribben, Sexton & Co., Chicago.
Culter, R. A., Culter & Proctor Stove Company, Peoria, Ill.
Dana, Geo. D., Excelsior Mfg. Company, St. Louis, Mo.
DuCharme, C. A., the Michigan Stove Company, Detroit, Mich.
Duffy, Jas., Duffy Trowbridge Stove Company, Hannibal, Mo.
Dugdale, Joseph T., Western Stove Mfg. Company, St. Louis, Mo.
Dwyer, James, Peninsular Stove Company, Detroit, Mich.
Dwyer, Jeremiah, the Michigan Stove Company, Detroit, Mich
Dwyer, John M., Peninsular Stove Company, Detroit, Mich.
Emery, J. W., Channon-Emery Stove Company, Quincy, Ill.
Emery, S. H., Jr., Channon Emery Stove Company, Quincy, Ill.
Gardner, Fred. W., the Michigan Stove Company, Chicago, Ill.
Goldschmidt, Julius, Brand Stove Company, Milwaukee, Wis.
Graff, H. L., Graff & Co., Pittsburgh, Pa.
Hanrahan, E. C., Peninsular Stove Company, Chicago, Ill.
Hayes, H. E., Bloomington Stove Company, Bloomington, Ill.
Hunter, John E., Culter & Proctor Stove Company, Peoria, Ill.
Kahn, Lazard, F. & L. Kahn & Bros., Hamilton, Ohio.
Kernan, Francis, Syracuse Stove Works, Syracuse, N. Y.
Lee, Fred. E., Beckwith Estate, Dowagiac, Mich.
Leonard, J. J., Toledo Stove Company, Toledo, Ohio.
Lounsbury, James A., Collins & Burgie Company, Chicago, Ill.
Miller, Theo., Art Stove Company, Detroit, Mich.
Moffatt, Albert, Collins & Burgie Company, Chicago, Ill.
Montgomery, J. F., Taunton Iron Works, Taunton, Mass.
Moore, Lewis, Joliet Stove Works, Joliet, Ill.
Moore, W. N., Joliet Stove Works, Joliet, Ill.
Mott, A. C., Abram Cox Stove Company, Philadelphia, Pa.
Mott, Ed. P., Abram Cox Stove Company, Chicago, Ill.
Orr, J. Allison, Mt. Penn Stove Works, Reading, Pa.
Patton, A. G., Patton Mfg. Company, Columbus, Ohio, and Jeffersonville, Ind.
Patton, W. D., Patton Mfg. Company, Jeffersonville, Ind.
Peck, E. W., Co-operative Foundry, Rochester, N. Y.
Perry, Nathan B., Perry Stove Company, Albany, N. Y.
Prizer, Chas. S., Orr, Painter & Co., Reading, Pa.
Pruden, A. K., St. Paul Stove Works, St. Paul, Minn.
Richardson, A. P., Richardson & Boynton Company, New York and Chicago.
Rogers, John, Home Stove Works, Chicago, Ill.
Ruso, James M., official stenographer, Albany, N. Y.
Ryley, A. G., H. Wetter Mfg. Company, Memphis, Tenn.
Sard, Grange, Rathbone, Sard & Co., Albany, N. Y.
Sard, Wm. H., Rathbone, Sard & Co., Chicago, Ill.
Scott, W. H., Sill Stove Works, Rochester, N. Y.
Seivard, H., Mt. Penn Stove Works, Reading, Pa.
Staufer, W. M., Buckwalter Stove Company, Royersford, Pa.
Stevenson, W. S., Thomas, Roberts, Stevenson Company, Philadelphia, Pa.
Thomas, D. M., secretary N. A. S. M., Chicago, Ill.
Thompson, Geo., Enterprise Stove Company, Vincennes, Ind.
Trowbridge, C. H., Duffy-Trowbridge Stove Company, Hannibal, Mo.
Van Cleave, J. W., Buck's Stove & Range Company, St. Louis, Mo.
Van Evera, De Witt, Brand Stove Company, Milwaukee, Wis.
Van Wormer, J., J. Van Wormer & Co., Albany, N. Y.
Venn, James A., Rathbone, Sard & Co., Aurora, Ill.
Viets, H. A., Fuller-Warren Company, Milwaukee, Wis.
Warren, Walter P., Fuller & Warren Company, Troy, N. Y.
Wells, I. H., Collins & Burgie Company, Chicago, Ill.
Wewers, Wm., Gem City Stove Mfg. Company, Quincy, Ill.
Will, Fred., Sill Stove Works, Rochester, N. Y.
Woodruff, J. M., J. Woodruff & Sons, Salem, Ohio.

The session was opened at 10.30 a.m. by President George D. Dana of St. Louis, who made an address in accordance with the usual custom, outlining the events of the year. Secretary D. M. Thomas also presented his official report of the work of the association, together with recommendations for the action of the convention.

A paper was then presented by the Fuller-Warren Company on "The Interchange of Information and Experience Between Stove Manufacturers," which was discussed at some length.

The afternoon session was opened by the reading of a paper on "Cleaning Castings," by Abram C. Mott. Next followed a paper by Henry Cribben on "The Education and Production of Efficient Workmen." Mr. Cribben's paper was so well received that a sufficient number of copies for every molder and apprentice in the country was ordered to be printed.

The Committee on the Secretary's Report submitted the following preamble and resolution, which were adopted as the sense of the convention:

The large decrease in the demand for stoves during the existing business depression, the decreased output and the maintenance by manufacturers of the same scale of wages heretofore paid have materially increased the cost of production.

The selling prices of stoves already so nearly approach the cost of producing and marketing them that any reduction of prices must result in serious demoralization and disaster.

The best interests of manufacturers, of dealers and of labor obviously require the exercise of a wise and confident conservatism through rigid adherence to existing prices and terms, therefore

Resolved by the National Association of stove manufacturers, that current prices and terms on stoves be firmly maintained during the year 1894.

The convention then adjourned until 10 o'clock on Thursday morning, after a session which was pronounced to be one of the most interesting and instructive ever held in the history of the association.

THURSDAY.

(*By Telegraph.*)

Only one session of the association was held on Thursday, and it was opened by the reading of a paper by J. Leon Gobeille of Cleveland, Ohio, on "A Theory of Ornamental Design as Applied to the Decoration of Stoves." The paper was an explication of the Newtonian theory that sound, color and form are all interconvertible and harmonious. It was illustrated with a large number of diagrams, Mr. Gobeille

presenting in colors the music of a hymn and then, by playing on a piano and violin, showing the principles deduced from the colors. The paper was listened to with deep interest and a vote of thanks was given the author at the close.

Charles S. Prizer of Reading, Pa., next read a paper on "Profit Sharing," which evoked considerable discussion. We shall make further note of the papers read at the convention in a later issue. After the reading of the papers the meeting proceeded to the election of officers for the ensuing year, the result being as follows:

President, George D. Dana, St. Louis.

First vice-president, Lazard Kahn, Hamilton, Ohio.

Second vice-president, Francis Kernan, Utica, N. Y.

Treasurer, W. S. Stevenson, Philadelphia.

Secretary, D. M. Thomas, 80 Broadway, New York.

Board of Management, H. W. Buttorff, Nashville, Tenn.; Henry Cribben, Chicago; C. A. DuCharme, Detroit; Frederick Will, Rochester, N. Y., and W. E. Walker, Taunton, Mass.

An assessment for expenses was then made, the same as last year, and Chicago was selected as the place for the next meeting. A discussion of the "Cost System" was then taken up, after which the convention closed its twenty-third annual session by adjournment.

Eavesdroppings.

— On Tuesday evening a number of the stove manufacturers accepted an invitation extended through George H. Barbour to visit the residence of James W. Ellsworth, on Michigan avenue. Mr. Ellsworth is one of the great coal operators of the country, but is perhaps better known as an art connoisseur and collector of curios. The gentlemen composing the party, in addition to Mr. Barbour, were Messrs. Nathan B. Perry, W. S. Stevenson, Jeremiah Dwyer, George D Dana, C. A. Du Charme, Grange Sard, Wm. H. Sard, A. C. Mott, C. H. Castle, E. W. Peck, Frederick Will, J. W. Vau Cleave, Edward Bowditch, Frederic W. Gardner, Alan W. Wood and a representative of *The Metal Worker*. They were received and warmly welcomed by Mr. Ellsworth, who took great pleasure in escorting his visitors through his spacious mansion and exhibiting the art treasures collected from all parts of the world. He has a superb art gallery, hung with paintings by the great masters, among which is one of Rembrandt's most famous works. Hours were spent most agreeably in the inspection of these as well as rare productions in bronze, old china, and artistic work of every description, including priceless treasures in ancient and modern books.

— As one of the visitors walked over a rug eight centuries old, a wicked associate vows that he remarked, "This rug is no older than I feel."

— Secretary Thomas is a sufferer from muscular rheumatism, which manifested itself particularly in his right hand, rendering it awkward on such an occasion as this, when greeting so many friends. He was the recipient of universal sympathy, and is now probably in possession of more remedies for and preventives of rheumatism than he had dreamed were in existence.

— The widespread publication a few days before the meeting of the convention that the smallpox had made its appearance in Chicago created consternation in the ranks of the stove men. Telegrams poured in on the local manufacturers inquiring the extent of the reported epidemic, and they had much trouble in satisfying the inquirers that it would be entirely safe for them to sojourn in the city for two or three days. One report in circulation was that the inspectors of the Board of Health were meeting every train on its entrance into Chicago for the purpose of vaccinating the passengers who could not show evidence of their having recently undergone that operation. The fear of being exposed to contagion in Chicago was at last allayed, but for a few days the chances seemed to be strongly in favor of the postponement of the time of meeting or the designation of some other city. The truth is that while smallpox has broken out in a few sections of the city it is by no means epidemic, and such vigorous efforts are being put forth by the health authorities to confine it to these localities that there seems to be little danger of its affecting the general health of the city.

— The condition of the stove trade was an unfailing topic of conversation among the manufacturers. Not a few stated that their foundries had closed down or were about to do so, as their stock of stoves seemed more than sufficient to supply whatever demand might be experienced for a considerable time. The maintenance of prices came in for considerable discussion in this connection. The general feeling appeared to be strongly in favor of keeping prices up to the old standard instead of trying to force business by making reductions. The argument was made that no greater number of stoves would be purchased even if consumers were offered inducements in the way of lower prices, while, on the other hand, there was a strong probability that the condition of demoralization that would inevitably ensue would result in an attempt to reduce wages and thus cause much friction and unpleasantness, which should be avoided if possible.

— The number of stove supply houses represented at the convention was smaller than in previous years. Some very familiar faces were missing which had beamed on stove conventions from time immemorial. The hard times and the paring of margins through excessive competition have undoubtedly had their effect on the stove supply trade, and this year's appropriations for stove convention expenses were either cut down or cut off.

— The Ireland & Matthews Mfg. Company of Detroit, Mich., had a representative on hand in the person of the genial C. H. Matthews, who made a fine display of top ornaments in one of the Auditorium parlors. The company manufacture hundreds of designs, but exhibited on this occasion a choice selection of the finest. The ancient statuette has now completely disappeared, and in its stead is a creation of filigree work, scrolls and curved bands, usually surrounding a spherical center. Opportunity is thus given for a great variety of shapes, decorations and finishes. The Ireland & Matthews Company do their own spinning, plating, &c., having a factory completely equipped for the production of the finest work of this character, including chandeliers. A novelty they are introducing this year is a nickel steel edge for ranges to take the place of the old cast edge, which is liable to warp and crack. Their edge is shaped in dies to conform precisely to the range for which it is made. They also showed fine new tile effects, with tiles of convex shape, painted by hand in pleasing tints. In connection with this exhibit were shown new draft slides just brought out by H A. Matthews of Waterbury, Conn. The peculiarity of these slides is the attachment of the knob. Instead of being riveted, the knob is held in place by a strong spring which pulls an inside washer tight against the reverse of the slide so that it cannot become loose. The knob is thus easily put in place, but once in position cannot be removed without pushing the knob in. The Ireland & Matthews Company presented the members of the convention, as a souvenir, a very pretty Waterbury watch, inscribed on the back, "We watch your interests," together with the date and the company's name.

— The Matthews & Willard Mfg. Company of Waterbury, Conn., were represented by E. A. Ireland, who made a very handsome exhibit of the company's products, comprising top ornaments, knobs, onyx tables and lamps. The top ornaments presented a fine array of very choice designs. Combinations of ormolu and white nickel were conspicuous in a great variety of detail. Perhaps the richest ornaments shown were wholly of ormolu, enriched with scroll work and open work. The managers of this company take pride in their exclusive designs, and their customers this year have purchased more expensive and artistic ornaments than ever before, to meet the requirements of advancing taste among consumers. The company make onyx tables of exquisite finish, trimmed with brass, and a large line of lamps. Every part of the work is done in their own factory.

— A. D. Stone represented the Worcester Ferrule & Mfg. Company of Worcester, Mass., and displayed a great variety of samples of their stove trimmings, comprising door knobs, hinge pins, damper slide knobs, towel rack knobs, &c. The company have greatly simplified the methods of manufacturing knobs since they first engaged in the business and yet have not impaired the quality of the goods in any respect. These knobs are manufactured of steel, which is drawn in dies to the proper shape, then polished and afterward nickeled. Considering the number of processes through which they pass, they are sold to the trade at marvelously low prices. The company have recently added to their line the manufacture of ball bearing steel cups and joint ferrules for bicycles. The joint ferrules are drawn from one piece of steel and take the place of expensive drop forgings.

— J. E. Gaitley of the Troy Nickel Works, Troy, N. Y., was in attendance upon the convention, but made no display of the products of the works, probably believing that everybody was sufficiently acquainted with the merits of the world renowned Alaska cold handled goods.

— Another manufacturer who was on the ground but made no display was W. F. Greene, of Troy, N. Y., maker of the Jewel and Crown stove knobs.

The Defense Association.

The Stove Founders' National Defense Association held their annual meeting on Tuesday afternoon, May 1, in the Auditorium Hotel, Chicago. It was well attended, but the proceedings were of much less importance than last year. Then there were two important subjects up for consideration. One was the threatening attitude of the molders, who were apparently determined to force an advance in wages. A conflict seemed imminent, as the leaders among the workingmen thought that they were entitled to an advance by reason of the prosperity which had existed in the stove trade for the previous two or three years. They could not see anything to interfere with another prosperous season for the stovemen, and considered the times propitious for demanding an advance. A delegation of molders had been appointed to attend the meeting of the Defense Association and to present their case. It was a strong delegation and made an excellent impression on the assembled manufacturers, but the latter were wiser in their forecast of the future, as subsequent events proved, and would not grant the desired advance, although it was urged so forcefully by the representatives of the workingmen. It was an exciting time, and the prospects seemed ripe for a trial at arms between employers and employed, when the request of the latter was turned down by a practically unanimous vote of the members of the association. The other important subject was the election of a

secretary. An attempt had been made to work up a hostile feeling against the re-election of D. M. Thomas, the efficient secretary of the association. It was futile, and Mr. Thomas was retained in his position by a vote which showed that he had a strong hold on the esteem of the members, and the opposition amounted to nothing.

This year there were no questions of this kind coming up for settlement. The molders are not looking for an advance in such times as these. They are satisfied if they can get employment at the old rate of wages, instead of suffering a heavy reduction, such as has afflicted their fellow workmen in other branches. The president of the association, Henry Cribben, had no report of an approaching conflict to give his official address any spice. The proceedings were of a tame character. The old officers were re-elected. The only changes made were the appointment of James Dwyer, Detroit, on the committee for the Third District in place of E. S. Barbour of Detroit, who retired, and Julius Goldschmidt of Milwaukee on committee for the Fourth District to fill the vacancy caused by the death of Frederick G. Brand of Milwaukee.

The Philadelphia Stove Trade.

The outlook for the stove trade in Philadelphia is not a bright one. The actual business done since the first of the year shows a decrease of about one-third in volume as compared with the business for the corresponding period of 1893. Founders all agree that unless there is a change in the general business condition of the country before July the prospect for a good season's trade will be slight. Three days a week is about the average running time of foundries, which means a production of little over half what it should be. The present production, however, with the stock carried over from last season, will afford an ample supply for the near future. Warehouses are already filling up, so it is unlikely that the present rate of production will be increased, unless a change for the better is soon noticeable.

A member of one of the largest firms of manufacturers makes the statement that they could almost close down until July 1, and only find themselves short on a few common goods. It is true that stocks in retailers' hands are light, but hand to mouth buying still continues. They are aware of the fact that the consumer is alive to the practice of economy and is prolonging, as well as he is able, the life of an old stove, and this fact was fully demonstrated by the heavy repair business of last season. Should business revive, however, the trade will be heavy, and it is in this hope that production goes on.

Prices seem to be satisfactory and steady, and the cutting which prevails so largely in other lines is noticed but little in the stove trade. Manufacturers seem content to take business as it comes, orders as a rule being too small to entail much competition. The present low price of iron makes little material change in the cost of a stove, the difference in most cases being met by an increase in the weight of the castings. There will be several new lines of goods placed on the market this season, chiefly in the form of square heaters and sheet iron goods, but very few of the new introductions will be of the high priced variety.

The Philadelphia building trade during the month of April took out permits for the erection of 1133 buildings, only 42 less than the number of permits taken out during the same month last year. Building operations, however, in the main are not as good financially as they have been. Stoves and furnaces are expected to be put into new dwellings and equities taken in payment for them. This plan is very unsatisfactory to the stove trade and is attended with considerable risk, as the equities are mostly in the shape of second mortgages, and in the case of a depreciation in the value of property much loss is likely to result.

Jobbers and retailers have found the business in summer goods on the whole very satisfactory. The business was late in opening, but so far has been large.

Collections show little, if any, improvement. Statements seem to have no effect upon tardy customers, and drafts are returned in some cases without remark. It is many years since a like condition was noticeable. It is probably chiefly owing to the retailers' own difficulties in the way of making collections, but in some cases manufacturers feel that the prevailing dullness is being taken advantage of to force extensions of credit.

A noticeable feature in the trade is the cheerfulness which prevails. Although the present prospect is poor manufacturers are on the lookout for a change, and when it comes they will not be found unprepared to take advantage of it.

The Van Wie Gas Stove Works

of Rockford, Ill., have just issued a 30page catalogue of their productions. They are manufacturers of Eclipse and Gilt Edge gas stoves. The illustrations begin with the Eclipse range No. 105, all cast iron, which has five burners on top and two burners for the baking and roasting ovens below. The No. 106 Eclipse is the same construction, except that it has steel sides and back. Nos. 107 and 108 have a broiler on brackets at the side. Nos. 109 and 110 have a water heater in place of the high broiler. Nos. 111 and 112 have a low water heater, with a warming oven over it, arranged at the side of the stove. Nos. 113 and 114 have a broiler placed over the warming oven and low water heater, thus bringing that part of the stove flush with the top of the main part. The New Eclipse range No. 55 is 32 inches high, has two large ventilated ovens and five burners on top. The Nos. 1 and 2 Eclipse have four burners on top and baking and roasting ovens below. The Nos. 10 and 11 Eclipse have three burners on top. The Gilt Edge ranges are cheaper ranges, but the manufacturers say "cheap only in price." They are shown in three styles. Then follow portable stoves of one, two and three burners each, in a variety of styles: lodge stoves, with very large tops and three and four burners, but in portable style; laundry stoves, with steel frames and two or three burners; water heaters of several kinds, to be used independently or in connection with cooking apparatus; an instantaneous water heater of new design and low in price; griddle cake baker, sad iron heater, gas soldering furnace and a gasoline stringer for use in changing gasoline to gas stoves.

Cupola Management.*—XI.

BY DR. EDWARD KIRK.

Daubing.

After the cupola is chipped out the lining is repaired with a soft plastic adhesive material known as daubing, with which all the holes that have been burned in the lining are filled up and thin places covered, and the lining given the best possible shape for melting and dumping. There are a number of substances used for this purpose, some of which are very refractory, and others possess scarcely any refractory properties whatever and are not at all suitable for the purpose. Molding sand is frequently used for a daubing. It is easily and quickly wet up and mixed, is very plastic and easily put on, but possesses none of the properties whatever requisite to a good daubing. It crumbles and falls off as soon as dry in exposed places, and a lining cannot be shaped with it. Furthermore, when put on in places from which it is not dislodged in throwing in the stock it melts and runs down and retards the melting by making a thick slag that is readily chilled over the tuyeres by the cold blast.

Some of the yellow and blue clays are very adhesive and refractory and make good daubing alone or when mixed with a refractory sand. Ground soapstone and some of the soapstone clays from coal mines make excellent daubing. But probably the best and most extensively used daubing is that composed of fire clay and one of the silica sands known under various names in different sections of the country and which I shall designate sharp sand. Fire clay is very plastic and adhesive when wet, but shrinks and cracks when dried rapidly. Sharp sand alone possesses no plastic or adhesive properties whatever and expands when heated. When these two substances, in exactly the right proportions, are thoroughly mixed, they make a daubing that is very plastic and adhesive, does not crack in drying, neither expands nor shrinks to any extent when heated, and resists the action of heat as well as fire brick in a cupola. When not evenly mixed the fire clay cracks and the sand expands and falls out of the clay when heated, making an uneven and uncertain daubing.

Fire clay absorbs water very slowly and it requires from 12 to 24 hours' soaking before it becomes sufficiently soft to be thoroughly and evenly mixed

*Copyrighted, 1894, by Dr. Edward Kirk.

with the sand. A large soaking tub should be provided near the cupola and it should be filled with clay every day after the cupola is made up and the clay covered with water and left to soak until the next heat. The clay and sand cannot be evenly mixed in a round tub with a shovel, so a long box and a good strong hoe should be provided for the purpose. The amount of sand a clay requires to make a good daubing varies from one-fourth to three-fourths, according to the qualities of the clay and sand, but generally one-half of each give good results. The sand is added to the clay dry, or nearly dry, and the daubing is made as thick and stiff as it can be applied to the lining and stick. The more it is worked in mixing the better, and if let lie in the mixing box for a day or two after mixing it makes a better daubing than if applied as soon as prepared.

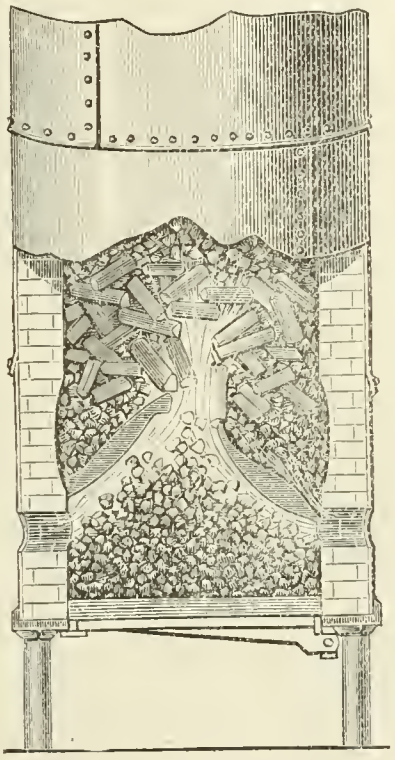
Nothing is gained by using a poor, cheap daubing, for it does not protect the brick lining, but falls off or melts into a thick tough slag which runs down and chills over the tuyeres and retards the melting by bunging up the cupola, and more fuel and time are required to run off the heat. The daubing is taken from the mixing box on a shovel when wanted for daubing and placed on a board under the cupola if the box is near at hand. When it is some distance from the cupola the daubing is placed in buckets or small boxes made for the purpose and conveyed to the cupola. The parts of the lining to be repaired are first brushed over with a wet brush to remove the dust and wet the lining so the daubing will stick better. The daubing is then thrown on to the lining with the hands in small handfuls; it can be made to penetrate the cracks and holes better in this way than in any other and stick better than when plastered on with a trowel. After the required amount has been thrown on in this way it is smoothed over with a trowel or wet brush and made as smooth as it can be made.

Shaping the Lining.

Daubing is applied to a lining for two purposes—viz., to protect the lining and to shape the cupola, and the latter is by far the most important of the two. A great many melters never pay any attention to it, their only aim being to keep up the lining, and they pride themselves on making a lining last for one, two or three years. Nothing is gained by making a lining last for years if the melting is retarded by doing so and enough fuel consumed and time and power wasted every month to pay for a new lining. Besides, a lining will last just as long when kept in a good shape for melting as when kept in a poor one, and the aim of the melter should be to put the lining in the best possible shape for melting and make it last as long as he can.

New linings are made straight from the bottom plate to the charging door when the cupola is not boshed. When it is boshed the cupola is made of a smaller diameter at and below the tuyeres, and the lining is sloped back to a larger diameter from about 6 inches above the tuyeres, with a long slope of 18 or 20 inches. In the straight cupola slag and cinder adhere to the lining just over the tuyeres every heat, and if not chipped off close to the brick after each heat gradually build out and in time a hard ledge forms that is difficult to remove. It furthermore reduces the melting capacity of the cupola by increasing the tendency to bridge. Above this point at the melting zone the lining burns away very rapidly and a hollow or belly is burned in it at this point every heat that requires repairing. Above the melting zone the lining burns away very slowly and evenly and seldom requires any repairing until it becomes so thin that it has to be replaced with a new one.

The cinder and slag that adhere to the lining just over the tuyeres must be chipped off close to the brick every heat and the lining made straight from the bottom plate to 6 inches above the top of the tuyeres. No projection or hump should ever be permitted to form or be made over the tuyeres to prevent iron running into the tuyeres of more than ½ or ¾ inch, and it should be placed right at the edge of the tuyere when it is thought necessary to make it. The upper edge of the tuyere lining should



Section through Bridged Cupola.

be made to project out a little further than the lower edge, and the brick lining should be cut away a little under each tuyere so that molten iron falling from the top of the tuyere will fall clear of the bottom side of the tuyere and not run into it.

It is not necessary or advisable to fill in the lining at the melting zone and make it perfectly straight, as it is when it is new, for a cupola melts better when bellied out at the melting zone. It must, however, be filled in to a sufficient extent for each heat to keep up the lining and prevent it being burned away to the casing. No sudden offsets or projections should be permitted to form or remain at the upper edge of the melting zone, for the stock lodges in settling upon projections and does not expand or spread out to fill a sudden offset, and so the heat passes up between the stock and lining and cuts away the lining very rapidly. No sudden offset or hollow should be permitted to form at the lower edge of the melting zone over the tuyeres, for the stock will lodge on it in settling and cause bridging of the cupola. The lining should be given a long taper from 6 inches above the tuyeres to the middle of the melting zone, and a reverse taper from there to the top of the melting zone. The belly in the lining should be made an oval shape, so the stock will expand and fill it as it settles from the top and not lodge at the bottom as it sinks down in melting. As the lining burns away above the melting zone the straight cupola assumes the shape of the boshed cupola, and only the lower taper is given to the melting zone.

Daubing should never be put on a lining more than 1 inch thick, except to fill up small holes, and even then small pieces of fire brick should be pressed into it to reduce the quantity of daubing and make it firmer. All clays dry slowly and give up their water of combination only when heated to a high temperature. When daubing is put on very thick it is only skin dried by the heat of the bed before the blast goes on. The intense heat created by the blast glazes the outside of the daubing before it is dried through to the lining, and as there is no way for the moisture to escape, it is forced back to the lining, where it is converted into steam and in escaping shatters the daubing or tears it loose from the lining at the top.

In the accompanying illustration is shown a sectional view of a cupola I saw at Richmond, Ind., in 1875. This cupola was a small one, about 35 inches diameter at the tuyeres, and the average heat was about 4 tons. The melter was a hard working German, who knew nothing about melting whatever, and his only aim was to keep up the lining in the cupola. With this object in view he would fill in the hollow formed in the lining every heat at the melting zone with a daubing of common yellow clay and make the lining straight from the tuyeres up. The daubing required to do this was from 2 to 4 inches thick all around the cupola, and was put on very wet. The heat dried and glazed this daubing on the outside before it was dried through. There being no way for the water to escape, it was converted into steam, and in escaping from behind the daubing tore it loose from the lining at the top. The fuel and stock in settling got down behind the daubing and pressed it out into the cupola from the lining until it formed a complete bridge, with only a small opening in the center through which the blast passed up into the stock. Before the heat was half over all the iron melted was running out at the tuyeres, and the bottom had to be dropped. When the cupola had cooled off the daubing and stock were found in the shape shown in the illustration, and when the bridge was broken down it was found to be composed entirely of daubing that had broken loose from the lining in a sheet and doubled over.

This melter always had slow melting and difficulty in dumping. Some nights after dumping he would work at the tuyeres with a bar until eight o'clock before he got a hole through, so the cupola would cool off by morning. The lining was not protected by the thick daubing, but was cut out more by the repeated bridging than if it had been properly coated with a thin daubing. I daubed this cupola properly and ran off two heats in it and melted the iron in less than half the time usually taken, and had no difficulty in dumping clean.

The lining of the boshed cupola does not burn out at the melting zone in the same shape nor to so great an extent as in the straight lined cupola, and in shaping the lining it is made almost straight from the top of the slope to the bosh up to the charging door. The

taper from the bosh to the lining should start at 6 inches above the top of the tuyeres, and should not be less than 18 or 20 inches long, and must be made smooth with a regular taper so the stock will not lodge on it in settling. Should the cupola be a small one with a thick lining and only slightly boshed and burn out at the melting zone similar to the straight cupola, it must be made up in the same way as the straight cupola. The great trouble with boshed cupolas is that the melter does not give a proper slope to the taper from the bosh, but permits a hollow to form in the lining over the tuyeres, in which the stock lodges in settling and causes bridging out over the tuyeres.

These directions for shaping the lining only apply to the common straight and boshed cupolas. Many of the patent and odd shaped cupolas require special directions for shaping and keeping up the lining as it burns out, and every manufacturer of such cupolas should furnish a framed blue print or other drawing, to be hung up near the cupola, showing the shape of the lining when new and the shape it should be put in as it burns away and becomes thin. Full printed directions should be given for chipping out and shaping the lining. All the improvements in cupolas are based on the arrangement of the tuyeres and shape of the lining, and when the lining gets out of shape the working of the tuyeres is disarranged, and the cupola is neither an improved one nor an old style, and is generally worse than either. More of the improved cupolas have been condemned and thrown out for want of drawings showing the shape of the lining and directions for keeping it up than for any other cause.

Early Stove Advertising Poetry.

The following letter from the Cleveland Co-operative Stove Company of Cleveland, Ohio, will doubtless be read with interest by many members of the trade:

The recent almost tragic death abroad of the well known writer, Miss Constance Fennimore Woolson, calls to mind the fact that probably her first literary efforts were in connection with the stove manufacturing business. Mr. Woolson, the father of the celebrated writer, was really the pioneer in the stove manufacturing business in the West. He established himself in a small way in the then village of Cleveland, and met with success. At the time of his death the firm of Woolson, Hitchcock & Carter were among the leading stove manufacturers of the country. After the death of Mr. Woolson and Mr. Carter, one of his partners, the concern was merged into the Franklin Stove Works, who later were succeeded by the present Cleveland Co-operative Stove Company. Almost the initial stove of Mr. Woolson's production was known as the Morning Star, which had a very large sale, and in the advertising of thia the first literary efforts of the poetess, then a mere child, were exerted. There were some eight or ten stanzas, which were printed and used by the trade as an advertising medium for the sale of the stove. Among the archives of the old concern have been found only three stanzas, reading as follows:

The Moruing Star is all the rage,
Because it suits in every age.
The people come both near and far,
Just to buy the Morning Star.

It suits the farmer's wife, they say,
Because it bakes well every day.
It suits the townsman just as good,
Because it burns so little wood.

If you'd have peace, comfort and bliss,
And at home enjoy each cherished wish,
And shun the rocks and clear the bar,
Then fail not to buy the Morniug Star.

A part of the third line of the last stanza quoted is not legible and may not be entirely accurate. Perhaps some of the older stove dealers can supply the missing verses.

ODD PLATES.

The mammoth counterpart of a nickel plated Garland range which formed the distinguishing feature of the exhibit of the Michigan Stove Company at the World's Columbian Exposition, has recently been placed in an elevated and prominent position in the area fronting the works of the company on Jefferson avenue, Detroit.

The many friends of E. S. Barbour, president of the Detroit Stove Works, will be interested in learning that his suit against the Wabash Railroad Company for damages on account of injurtes received by an accident in a train near Crown Point in May, 1892, has been decided in his favor. The jury were out but a short time and brought in a verdict awarding Mr. Barbour $5000. After the announcement of the verdict the counsel for the defendants stated that an appeal would be taken to the higher courts.

The Monroe Foundry & Furnace Company of Monroe, Mich., have sent us a very attractive catalogue relating to the Floral City furnaces, which they manufacture in several varieties. The volume is made up of about 100 pages of letterpress, printed in tinted ink upon good paper and bound in attractively ornamented colored paper covers. The aim of the concern in issuing this publication has been not to enter into an extended discussion of scientific heating and ventilation, but rather to present a few general laws which experience has shown to be practical, and invite a careful investigation of the conspicuous merits embodied in the Floral City furnace. The early pages contain remarks on warming and ventilation, followed by a description of the goods named. Scattered through the volume are half-tone engravings of buildings, public and private, in connection with which the company's goods have been used. Numerous tables are also presented, giving the dimensions and heating capacity of the Floral City furnaces; also capacity of pipes and registers. The latter portion of the volume is given up to extracts of testimonial letters, as well as to a long list of some of the persons using and dealing in the company's goods. The makers state that they have during the past ten years made a special study of the heating and ventilation of churches, school houses and other public buildings, and are prepared to give satisfaction in every case. In addition to the warm air furnaces the company offer the trade a line of combination warm air and hot water heaters, reference to which is made in the pages of the catalogue.

According to dispatches to the daily press from Mansfield, Ohio, the most severe wind and rain storm experienced in years passed over that section on the evening of Saturday, April 28. Reports from neighboring towns are to the effect that much damage was done to buildings, trees and fences, and that in Mansfield many structures were unroofed, among them being the Eclipse Stove Works.

Anson Ingraham, one of the oldeat and best known citizens of Washington County, N.Y., died at his home in Center Cambridge, April 21. He was born in Pittstown, Rensselaer County, N.Y., in 1811. He went to Center Cambridge 62 years ago and established a general store. His business grew rapidly and he branched out in several enterprises, one being the manufacture of stoves at Troy. Later he became the senior member of the firm of A. Ingraham & Co.

Last week some interesting experimeents with a straw burning cook stove were made in Minneapolis, Minn. The stove is the invention of D. R. Hoopes, is constructed of sheet steel, and the upper portion does not differ essentially from that of the ordinary coal burning stove. Two fuel doors open from the front, and are intended for the insertion of large cartridges in which the straw, hay, corn cobs or stalks are placed. In general appearance the cartridges must resemble an exaggerated shot gun shell, except that in place of the cap is a small round hole which is used as an upper draft through the shell. On one side of the cartridge is a 3-inch draft, which extends the entire length—27 inches. It is crated from above by three strips of iron, which run the entire length and keep the charge of fuel from falling down into the draft and choking it up. The cartridges are run in on two girders of iron, and with one charge, it is claimed, the stove will run for an hour under ordinary circumstances. The oven is located beneath the fire box or cartridges, and the flame is carried over it down the front of the stove and underneath the oven. The concern which has been formed to manufacture this device is known as the Straw Burner Stove Company, with offices in the Loan & Trust Building, Minneapolis, Minn. At present the stove is being made at the shops of the Peteler Car Works, where the experiments referred to were carried out.

Granoe Sard of Albany, N. Y., has taken a cottage for the summer at Magnolia, Mass., where he will spend a portion of his time.

The James Spear Stove & Heating Company, Philadelphia, are to furnish the ranges for a building operation of 400 houses at Overbrook, Pa.

The Superior Stove Company of Superior, Wis., have had under consideration an increase in the capital stock to $50,000. At the date of latest advices it was the intention of the company to resume operations this week and on a scale which would enable them to fill the orders already booked and take care of those which were expected to follow.

A very appreciative article concerning the Culter & Proctor Stove Company appears in the Peoria (Ill.) *Journal* of the 24th ult. The extent of the company's plant is stated, and the character of the goods made is set forth in full. From the general tone of the article the inference is drawn that the company are favored with good business, on which they are to be congratulated.

The recently organized and thoroughly equipped plant of the Central Stove Works Company of Lebanon, Pa., resumed operations on Monday, April 23, and the first cast was made on

Wednesday, the 25th. The works are now in good shape for business and the company propose turning out a line of stoves which will take a high rank as well as prove very popular with the trade. The officers and management are said to be more than pleased with the favorable start which has been made.

THE MANUFACTURERS' STOVE REPAIR COMPANY of Chicago were recently incorporated, with a capital of $15,000. The incorporators include Oscar Ludwig, William D. Meeker and J. Henry Delms.

OPERATIONS have recently been commenced in all departments of the plant of Zebulon Hunt, at Hudson, N. Y. A reduction of 10 per cent. was made in the molding shop, but as soon as business revives somewhat the old scale, it is said, will go into effect.

THE MOBILE STOVE & NOVELTY WORKS of Mobile, Ala., were recently organized, and the plant will be located on the site of the old cotton mill, at the corner of Theater and Royal streets. The Edgar-Nelson Foundry Company will also be consolidated with the new concern.

THE JOLIET STOVE WORKS of Joliet, Ill., are sending out a neat calendar for the month of May, in combination with which is an illustration of Moore's Air-Tight heater. The stove is shown with and without casing. The text states that in 1891 Moore's Air-Tight heater was an experiment, in 1892 it was an acknowledged success, in the panic year, 1893, the company sold twice as many as in 1892, while for 1894 it is intimated that "it is time for every live dealer who values the agency of a profitable specialty to procure it."

THE PORTLAND STOVE FOUNDRY COMPANY, Portland, Maine, recently purchased a brick building on Kennebec street and propose to open a retail department. One of the latest productions of the company is an aluminum tea kettle, which they are now placing on the market.

THE CRAIG-REYNOLDS FOUNDRY COMPANY of Dayton, Ohio, present in an attractive catalogue, which has just been issued from the press, some remarks relative to the Triumph warm air furnaces which they manufacture. These goods are the result of years of experience and observation and are said to "combine every convenience and improvement that modern inventive genius can devise. They have been constructed with especial reference to heating capacity, durability and economy, as well as common sense principles of sanitary heating and ventilation, and are manufactured with special reference to the economical and thorough heating of residences, churches and schools." The Triumph furnaces are adapted for using hard or soft coal and are made in three sizes, portable form. The Triumph King, likewise arranged for burning hard or soft coal, is made in portable form and also for brick work. It is made in four sizes and has fire pots ranging from 20½ inches in diameter in the smallest size up to 30 inches in diameter in the largest size. The catalogue consists of 16 pages, is neatly printed and is bound in attractive covers.

SAM S. UTTER of 113 Beekman street, New York, has received from his foundry a new oil stove known as the No. 40 Game Lamp. It has a four hole top and is finished in either plain black or nickel plated. The tank is made in one piece and is regarded as a great improvement over the old style. Mr. Utter appointed on a recent Western trip the following agents in the cities named: Burtis & Co., Troy, N. Y.; C. B. Baker, Cleveland, Ohio; O K. Stove Company, Louisville, Ky.: Freeman, Delamater & Co., Detroit, Mich.; Jacob Retterer, Chicago; A. J. Lindemann & Hoverson Co., Milwaukee, Wis., and the Maxwell Brokerage Company, Denver, Col. The agent for the Eastern States is H. M. Carey, located at Boston, Mass.

RATHBONE, SARD & CO. have been granted this year two patents on their Acorn radiator, one covering the design and the other the construction. The patents embody the essential features which have made the stove so popular with the trade. The makers, we understand, have no desire to monopolize so important an invention, and have decided to offer to a limited number a license to use the inventions described in letters patent No 516 617 and covering the constructive features of the stove, but they will not license any one to use their design patents.

THE ELLWOOD GAS STOVE & STAMPING COMPANY of Ellwood City, Pa., have placed on the market a new gasoline stove known as the Perfect Safety. It is a new cheap step stove, made in two sizes, one having two individual burners and the other three in the top surface, and a double burner on the step at the left. The area of the top of the smaller size measures 15 x 22 inches, while that of the larger is 16 x 32 inches, the hight from the floor being in each case 29 inches. The step is 12 x 18 inches in area and stands 22 inches from the floor. These goods are provided with the company's removable automatic shut off Perfect Safety tanks. The stoves are referred to as being light, strong and durable, made of stamped steel throughout, neatly japanned and ornamented.

THE SUPERIOR FURNACE COMPANY of Little Falls, N. Y., are directing the attention of the trade to their lines of specialties by means of a neat folder, lithographed in colors. Illustrations are given of the Superior steel range, which is shown with high closet and reservoir; the new warm air Superior heater with top return flue and adapted for hard or soft coal; the Superior furnace with heavy all cast iron dome and either steel or cast iron radiator, and the Superior dome furnace, intended for using hard or soft coal, coke or wood as a fuel.

THE LITERARY DEPARTMENT of the Michigan Stove Company has favored us with two entertaining poems, daintily gotten up, nicely printed, and altogether captivating. One is entitled "So Different," and illustrates sundry trials in wedded life which were only ended when an investment was made in a Garland stove. The other is entitled "Stoves and Sunshine," and is a eulogy of the Yankee stove by Eugene Field, who versifies his experience in countries unblessed by the heat giving apparatus which is in vogue throughout this country.

R. ROBINSON & SONS, 105 Lake street, Chicago, are agents for the Northwest for the Model steel range made at Portsmouth, Ohio, and have succeeded in establishing a fair trade for it.

F. MEYER & BROTHER COMPANY of Peoria, Ill., have recently engaged in the manufacture of the Weir gas and soot burning furnace for heating with warm air. They have just issued a handbook of hints on warming and ventilation entitled "The House Comfortable." The book contains 48 pages, of which the first 32 pages are taken up with a very interesting treatise on warming and ventilation. The writer is evidently a man of long and varied experience and possessed of a high power of searching investigation, while he is at the same time a master of vigorous English. His illustrations are forcible and always well pointed, and his suggestions are eminently practical. The remainder of the book is devoted to setting forth the special features of the Weir furnace, of which full illustrations are given, portable and brick set, perspective and sectional. Scattered throughout the book are illustrations of buildings in which the Weir furnace is used for heating.

WE HAVE RECEIVED from the William G. Fischer Mfg. Company, Kokomo, Ind., four fine photographs of their Columbian wrought range. One shows the range with a high shelf, another with high shelf and low closet, the third with high closet, while the fourth is a double oven range with high shelf and low closets. A description of this range was given in a previous issue.

THE BUCKWALTER STOVE COMPANY of Royersford, Pa., will this season introduce to the trade the Star Canopy, a five or six hole range, in six sizes. It has a side ash pit, right or left oven door, nickeled name and number plate, elevated shelf, and will be furnished with or without a reservoir. Another new range will be the Bright Canopy, a full six hole range in four sizes. In square heaters they will introduce the Colossus, a high priced stove with full revertible flue and fully nickeled. They will also have ready for the season's trade the Gem Ringgold, a handsomely finished and nickeled cheap square parlor heater; and the Aldine, a sheet iron base burner. Their Laura sheet iron double heater will be somewhat changed and will appear this season with sliding doors.

THE GRANDER STOVE COMPANY of Royersford, Pa., are preparing some additions to their lines for the coming season's trade. In ranges they will introduce the Venus, a six hole range made in two sizes, with and without reservoir, large front ash pit, right hand oven door, pipe shelf and elevated warming shelf. A first-class range in every respect. Another range will be the Mentor, a medium priced article in two sizes, five and six holes, with side ash pit, right and left oven doors, with and without reservoir, and pipe shelf. In heating stoves they will bring out the Milton, a medium priced sheet iron base burner. Their line of Volga square heaters which they put on the market last season will be augmented by the addition of a larger size, to be known as No. 15, made in two parts and heavily constructed. They will make an addition to their line of Mars square heaters by the introduction of a new direct draft and revertible flue single heater. Their Bride range is to be redressed, and will appear with a new skirt and pipe shelf.

THE MOUNT PENN STOVE WORKS of Reading, Pa., will place on the market this season some new goods, among them the Penn Pride, a sheet iron base burning stove, half revertible flue, nickeled base and foot rail, nickeled crown top band and full nickeled swing cover; the Penn Pearl, another sheet iron base burner, with full revertible flue and double foot rail; the Penn

Coin, also a sheet iron base burner, with straight draft and single foot rail; the Penn Prize, a full nickeled square heater, in single and double styles, designed to meet the demand for a cheap square stove. Their line of furnaces will be augmented by the Palace, a steel drum furnace with horizontal hot air flues, and made in sizes running from the size suited to the requirements of a very small house upward. This furnace is constructed to meet the market for an extremely cheap article. They are reconstructiug the Penn City, a small five or six hole range with stationary ash pit, and the Penn Item, a small six hole range with detachable hearth. The appearance of these ranges will be much improved.

The Michigan Stove Company have prepared a large pictorial hanger which they are now distributing to their customers. It is intended as a time saver, but also answers an excellent purpose as a constant advertisement This hanger is 44 x 27 inches in size and is devoted to the new Garland cooking goods. It shows handsomely engraved pictures of 32 different ranges and cooking stoves manufactured by the company, and thus saves merchants and salesmen the trouble of referring to the catalogue. The hanger is printed in colors, the background being a light blue, around which runs a neat crimson border, while ornamental scrolls separate the nine groups of ranges and stoves from one another. In the matter of cast ranges four styles are shown for each group. In cooking stoves three styles are shown for each group. There are two groups of wrought ranges with three styles in each group. In looking over this array of fine cooking goods the thought naturally occurs that the man or woman who cannot be suited in such a collection must be extremely hard to please.

John P. Schaffer, 18 Wood street, Pittsburgh, Pa., manufacturers of the Novelty wall pipe, has just returned from his regular spring visit to the East, where he has been looking after the interests of his goods and purchasing stock for the coming season.

The New York office of the Howard Furnace Company celebrated May Day by a new coat of varnish on the sample of the Howard furnace which is in front of their place at 210 Water street. They will furnish five combination Howard furnaces for some residences in course of erection at Twenty-second and Walnut streets, Philadelphia.

W. G. Greamer & Co., 96 John street, New York, have in course of completion some new designs in hot air registers which will be ready for the trade during the summer. They make a specialty of brass goods, and show a fine line of tea kettles of ornamental design, such as are used with an alcohol lamp.

W. H. Pfahler, treasurer of the Abram Cox Stove Company, Philadelphia, made a visit to the New York office at 305 Pearl street this week.

The following item relative to the extending use of gas stoves is taken from a recent issue of one of the New York dailies: During the last five years a great deal of money has been invested in the perfection and manufacture of gas appliances, and the missionary work which the agents of these different manufactories have been making in the different cities, especially in New York, is beginning to tell. Last summer a large number of apartment houses were fitted up exclusively with gas stoves. These experiments gave such satisfaction that not only apartment house proprietors, but individual renters of flats are making for these conveniences, which secure perfect combustion, the saving of hours of time, money and discomfort. It is estimated that when gas stoves are substituted for the old fashioned coal furnaces the radiant heat of New York will materially diminish, and this is a matter of importance to the many who must live in New York all the year round and in apartment houses provided with a blazing coal stove in each apartment from early morning until nightfall. In London 150,000 gas ranges are already in use, and it is believed that New York will follow the example very quickly.

Gasoline stove manufacturers have for years been handicapped by the almost universal opinion that gasoline stoves are dangerous, and this opinion has been encouraged by the daily press reports of what are styled "gasoline stove explosions." C. A. Stockstrom, secretary of the Ringen Stove Company, gives a case in point. A few days since an explosion occurred in a dwelling house in St. Louis, where the occupants had a gasoline stove, the explosion resulting in the death of two persons and the serious injury of two others. The daily press heralded the explosion in their usual manner, heading it "Terri ble gasoline stove explosion." The facts in the case are as follows: The man of the household had gone out to procure a quantity of gasoline, and had it in a 5-gallon glass jar, with glass handle. Entering the summer kitchen where the gasoline stove was in operation the weight of the gasoline caused the handle to break and the jar falling to the floor broke. An explosion followed, as a matter of course. The gasoline stove was in no way to blame, as had an ordinary cook stove been in use the same explosion would have occurred. It would be well for dealers in whose localities so-called gasoline stove explosions occur to investigate the circumstances, and in nearly all cases the fault will be found, not with the stove, but in the carelessness of the operator.

One of the newest productions of the Kernan Furnace Company, Utica, N. Y., is the Kernan range. It is of the double oven variety and is made in three sizes. It is furnished with either a plain, Dockash or duplex grate, and all arranged so that they can be removed through the front without difficulty. The fire chamber is of ample size and fitted with a reversible water back, that can be used on either side of the fire chamber. The ranges are provided with warming ovens and have a handsome high shelf, large flues and free access to them for cleaning being special features. In size and shape the range has been designed to meet the requirements of the New York market.

Exports of stoves and ranges and parts of the same from the United States to foreign countries during the nine months ended March 31, 1893, were of the value of $178,175, as compared with $161,446 in the corresponding period of last year.

Harry King, representative of the Kernan Furnace Company of Utica, N. Y., is making New York City his headquarters while visiting the trade in near by towns. *The Metal Worker* was favored by a call, when his line was shown by nickel plated model and the features explained. The man who sells the goods is always a welcome visitor.

The Bulkeley is the latest addition to the line of furnaces of the Bulkeley Stove & Range Company, 104th street and Lexington avenue, New York. Those that were in use during the past winter are said to have given excellent satisfaction.

M. Abbott's Sons, Seventeenth street and Eighth avenue, New York, are making a specialty of their hot air furnace business. They have a full line of furnaces on their sample floor which they call the Union. They are provided with a labor saving grate, and the radiator is so constructed as to present a large heating surface and effect an indirect draft.

A. L. Canfield, the New York representative of the Danville Stove & Mfg. Company, Danville, Pa., has many attractions for the stove dealer at 284 Pearl street. The company are the Eastern agents for the Monarch gasoline stoves made by the Baxter Stove Company of Mansfield, Ohio, and report a growing interest in this line of goods in New York and vicinity. A display is made of every variety of these stoves from the cabinet Monarch to the low junior. They are also agents for the Model steel ranges, made by the Portsmouth Stove & Range Company of Portsmouth, Ohio, and find that these goods are being shown some favor by the builders in this vicinity. The large flues used in steel range construction enable these goods to prove satisfactory in operation in chimneys where the cast iron ranges with flues of less generous proportions fail to give prompt and satisfactory results. These ranges are provided with all the labor saving devices of high-class goods, and are of very attractive appearance. They have just put on the floor the new Queen Beaver, their highest grade range. In design and ornamentation this range is quite handsome. It is provided with either a triplex or duplex grate, has ventilated oven, cut centers and a top which, they claim, is specially adapted to overcome the breaks frequently occurring in range tops and to maintain a continuously level top. The range is made with ovens 21 and 23 inches square and 13 and 14 inches high. It is furnished with the Waterman or a non expanding cover. It is set on a heavy ornamental base, has a nickel plated top edge and an ornamental nickel plated back guard, to which swinging plate warmers are attached. The 8-16 is a new size added to their line of the King Beaver that has a nickel back guard, and a feature which will be attractive to the housewife is a large and convenient ash pan.

The Ontario Bureau of Mines has received information of a discovery of tin ore which, it is claimed, has been made in the vicinity of Sudbury, Canada.

Early in May will begin the competitive tests of machine guns at the Indian Head proving grounds. Several types will be submitted, including the Gatling, Accles, Maxim, Gardner and others. From these weapons one will be selected for adoption in the naval service, in order to secure a uniform class of guns and ammunition for all the ships. At present two or three styles of machine guns are provided for the navy, there being no standard.

TRADE REPORT.

The Iron Market.

The situation is dominated by the Coal and Coke strikes. So far as the producing interests are concerned the state of affairs is very much mixed. The blast furnaces of the valleys and of the Pittsburgh, Wheeling and Cleveland districts have felt the Coke strike first. Edgar Thomson, Laughlin and Stewart have stock enough to carry them along. The majority of the other stacks have either banked or blown out or will do so within a short time.

Even some of the furnaces in Central Pennsylvania who could use anthracite threaten to bank because it would run up the cost. The anthracite stacks proper will find their capacity reduced when the usual admixture of Coke to the burden is dropped.

In the foundry grades of Pig Iron there has been no stiffening, because until now the Southern plants have kept running. Besides, there is quite a fair stock for the moderate current demand.

As for the strike itself, the general opinion is that the men are hardly in a condition for long idleness. Besides, there is the significant fact that the Flat Top and Cumberland districts, two very large contributors to the supply, are fully at work.

On the other hand, it is conceded that wages in some sections have been unduly low, and it is rumored that some interests in the Connellaville region will grant the demands of the men. A very weak point of the position of the labor leaders is that they will not allow resumption, even if the demands are granted, locally, unless the surrender of the operators has been general.

Pig Iron.—The New York and New England markets have been very quiet and have not as yet been affected in any way by the Coal strike. It is probable, however, that some of the Alabama furnaces will have to bank if the labor situation does not soon improve in that district. In Bessemer Pig we note a sale of 10,000 tons at private terms by an Eastern Steel works. We quote standard brands $12.50 @ $13.25 for No. 1; $11.25 @ $12 for No. 2, at tidewater. Southern Iron, same delivery, $11.50 @ $12.25 for No. 1; $10.50 @ $11 for No. 2; $10 @ $10.25 for No. 3; $10.25 @ $10.75 for No. 2 Soft, and $10.50 @ $11 for No. 1 Soft. Foundry No. 4 (Foundry Forge) is $9 75 @ $10.25.

Our Philadelphia representative writes as follows in regard to the Pig Iron market in that district: Foundry Irons are not affected by the strike to the same extent as those used for Steel making, and while there is a fairly good demand, buyers can get almost anything they want at last week's prices. Eventually, however, it will affect both ends of the market, as Pig metal can neither be consumed nor produced without the regular fuel supply, so that what affects one will affect the other. Under these circumstances there is no movement to indicate any decided change in values in either direction, sellers being about as anxious to do business at former prices as they usually are, particularly when the order is from gilt edged parties. Quotations are so diverse that they can only be given in general terms. Some buyers claim to be getting first-class No. 2 Foundry X at very close to $11, delivered at points equal to Philadelphia, while sellers of leading brands claim $12 @ $12 25 as their minimum. The question arises whether the low priced Iron is of the grade represented, but as it answers the purpose of the consumer the name or grade is of little account. This is doubtless a temporary condition, and the quotations herewith given are merely a general indication of what sellers ask, rather than as representing actual sales—except in a small way:

Standard No. 1 Foundry X	$12.50 @ $12.75
Standard No. 2 Foundry X	11.75 @ 12 25
No. 2 Plain	10.75 @ 11.00
No. 1 Soft	11.50 @ 12.00
No. 2 Soft	10.75 @ 11 00

In the Chicago market transactions in local Coke Iron have been on a little better scale, but Southern Iron shows no improvement whatever. The Coal strike in the South has not yet caused prices to be advanced by the Southern companies, although sales agents are daily in expectation of orders to mark up their rates. Lake Superior Charcoal continues neglected. Quotations are given as follows for cash:

Lake Superior Charcoal	$15.00 @ $15.50
Local Coke Foundry, No. 1	11.25 @ 11.50
Local Coke Foundry, No. 2	10.50 @ 11.00
Local Coke Foundry, No. 3	10.00 @ 10 50
Local Scotch	11.50 @ 11.75
Ohio Strong Softeners No. 1	12.60 @ 13.50
Southern Silvery, No. 1	..... @ 11.50
Southern Silvery, No. 2	..... @ 11.00
Southern Coke, No. 2	10.00 @ 10.35
Southern Coke, No. 3	9.75 @ 10.00
Southern, No. 1, Soft	10.25 @ 10.50
Southern, No. 2, Soft	9.75 @ 10.00
Tennessee Charcoal, No. 1	15.00 @ 15.50
Tennessee Charcoal, No. 2	14.50 @ 15.00
Alabama Car Wheel	17.85 @ 18.00
Jackson County Silvery	15.00 @ 16.00
Other Ohio Silvery	12.50 @ 13.00

The Coke strike has caused the shutting down of many furnaces in the Pittsburgh district, and has brought about a famine in Bessemer Iron for close delivery, so that it can hardly be had at any price. Buyers are taking only what material they absolutely need, but for such purchases they are paying from 50¢ to $1 advance. Foundry Irons are firmer and for close delivery show a slight advance. For prompt delivery the following quotations are ruling:

No. 1 Foundry	$11.25 @ $11.50, cash
No. 2 Foundry	10.40 @ 10.75 "
No. 3 Foundry	10.00 @ 10.25 "

Sales are noted by our Pittsburgh agent of 25 tons of No. 2 Foundry at $10.40, 25 tons at $10.60 and 50 tons at $10 75, for May delivery.

Advices from St. Louis indicate that the Coal strike has not as yet had any effect on prices in that market, and there seems to be plenty of Iron to fill all orders for the present. Transactions are almost entirely confined to small lots, the largest single sales for the week running up to 300 tons. Quotations are made as follows for cash, f.o.b. cars St. Louis:

Southern Coke, No. 1 Foundry	$10.75 @ $11.00
Southern Coke, No. 2 Foundry	9.75 @ 10.00
Southern Coke, No. 3 Foundry	9.50 @ 9.75
Southern Car Wheel	16.75 @ 17.75
Lake Superior Car Wheel	16.25 @ 16.50
Ohio Softeners	14.25 @ 14.50

Business during the week in the Cincinnati district has been very dull. The only transaction beyond the few current consumption sales, which were inconsiderable, was a sale of 1500 tons of No. 2 Foundry, and this was made on the basis of $675, f.o.b. Birmingham, and for long forward delivery. Consumers in the district have about all the Pig Iron they require in the early future under contract, and there are few applications from the East or elsewhere for new supplies. Quotations are unchanged, but are scarcely more than nominal, as follows:

Southern Coke, No. 1	$10.25 @ $10.50
Southern Coke, No. 2	9.25 @ 9.50
Southern Coke, No. 3	8.75 @ 9.00
Ohio Soft Stone Coal, No. 1	14.50 @ 15.50
Ohio Soft Stone Coal, No. 2	14.00 @ 14.50
Lake Superior Coke, No. 1	12.50 @ 13.00
Lake Superior Coke, No. 2	11.50 @ 12.00
Hanging Rock Charcoal, No. 1	17.00 @ 17.50
Hanging Rock Charcoal, No. 2	16.50 @ 17.00
Tennessee Charcoal, No. 1	13.00 @ 13.50
Tennessee Charcoal, No. 2	12.00 @ 12.50
Standard Southern Car Wheel	16.25 @ 17.00
Lake Superior Car Wheel and Malleable	16.25 @ 16.75

There has been no change in Pig Iron prices in the Louisville, Ky., market as a result of the Coke strike. Furnaces are, however, not inclined to sell heavily until they see the effect upon the Iron industry of the disturbances in the coal fields. Among Pipe shops, Car shops, and Stove foundries there is yet great complaint of the low prices finished materials have to be sold at. Quotations, for cash, f.o.b. cars Louisville, Ky., are as follows:

Southern Coke, No. 1 Foundry	$10.25 @ $10.50
Southern Coke, No. 2 Foundry	8.75 @ 9.25
Southern Coke, No. 3 Foundry	8.50 @ 8.75

Metal Market.

Pig Tin.—There has been a sharp rise in prices and more activity in business. Even the speculative branch of the trade has been infused with a little animation, making, in all, a condition of affairs somewhat in contrast with the flatness that prevailed up to within a very recent date. At the end of last week dealings were recorded to the extent of 150 tons at 19.75¢ @ 19.85¢ spot, 19.67½¢ May delivery, 19 67½¢ June, and 19.70¢ September. On Tuesday the interest became livelier and carried prices still higher in the face of a bank holiday in London. Sales were recorded to the extent of 75 tons at 20.05¢ @ 20.10¢ for May delivery, 19.95¢ for June, 19.95¢ for July and 20¢ for August, while as high as 20⅛¢ was bid for spot. In the latter there was a clean advance of 0.42½¢ from the lowest point of the week, and the distant futures moved up to the extent of about 0.30¢ during the interval. The feeling was somewhat quieter later in the week, but offerings at less than 20.15¢ were the exception on either prompt or future delivery. Prices for small lots of the metal are unchanged at last week's quotations—namely, 21¢ @ 21¼¢ per lb for Straits Pig, with an advance of 1¢ per lb in Bars.

Copper.—The market is rather weaker in appearance. Offerings of Lake Su-

perior Ingot at 9½¢ have not met with response except where very small quantities were involved. Fair sized lots offered at 9.45¢ found very limited outlet and poor results attended efforts to draw out bids of 9.40¢ on larger quantities. As not unusual on a soft market, rumor had it that still lower prices were not out of the question, since the European market has not netted over the parity of 9¼¢ for some time past. Electrolytic apparently stands in rather better position, since home purchases continue on a fair scale and 8¾¢ @ 9¼¢ cover the extremes of prices. Casting stock has not varied from 9¢ @ 9¼¢ in price, but finds merely routine sale. Jobbing business in both Ingot and Manufactured Copper has been unusually limited in extent, while prices are inclined to be soft.

Pig Lead.—There has been slightly freer offerings by some producers. Speculators who carried a few carloads since early in the year unloaded also. Both movements came just at a time when consumers were very indifferent buyers. Between them they forced prices lower and for a time gave the market a weak appearance. About five carloads went at 3⅞¢. That, however, disposed of the liquidation. Subsequent bids of the price named were ineffective in leading to business, and 3.42½¢ @ 3 45¢ would now seem to be strictly inside rates for Western brands. Bids of 3 40¢ were refused. Nothing more than a routine business is doing and consumers evince little interest beyond the supplying their absolute needs. Jobbers' prices for small quantities of American Pig rule at about 3¾¢ @ 4¢ ℔ lb.

Lead Sheet and Pipe.—The market for Plumbers' Supplies in this vicinity is extremely dull. Building operations in hand are so limited and those in prospect are so uncertain that the demand for this class of material has fallen far below the average. This condition of things, however, seems to be more or less local, as reports from other sections of the country are much more favorable. Prices for Lead Pipe and Sheet Lead, while nominally maintained, as per list, can without much difficulty be shaded.

Spelter.—Since our last report a good portion of late accumulation in the West has been disposed of. This and the fact that production has been reduced considerably served to stiffen prices and give the market better tone. Eastern consumers, however, have purchased in a moderate way and are indifferent buyers at the present time. On good Western brands the popular quotations are 3.55¢ @ 3.60¢ for delivery here or at common point, with an advance of about ¼¢ ℔ lb on small lots from store.

Tin Plates.—No improvement can be noted in the demand for any line of Plates. The market appears soft as well as peculiarly dull for this season of the year. Orders run quite as small as they did a week ago, and are not more numerous, although some dealers mention a slightly increased interest in future deliveries. On the whole, the market is commonplace and business disappointing. The first days of each month usually bring in to the dealers an accession of orders from the smaller trade, but nothing of the kind has occurred at this time. The demoralization of the trade is attributed on all hands to the uncertainty existing in regard to the tariff. Stocks are in such a shape that when that question is settled, or in a fair way to be so, the chances are in favor of a good movement of business. Shipments from Europe continue comparatively small, and stocks on this side, both in and out of bond, are lower than has been the case for years. Importers find it cheaper, under present conditions, to carry their purchases of Plates on the other side, sending over for them as they may be needed. Even some of the larger consumers are leaving portions of their purchased stocks in bond at American ports and drawing from them gradually according to their requirements. Prices are inclined to weakness, concessions being easily made on desirable orders. A London cable dispatch to *The Iron Age*, dated May 2, reports on the British market as follows: The Tin Plate market remains dull, although there has been rather more doing in 14 x 20 Cokes for prompt shipment. Prices continue low and rather weak. Stocks at Swansea are now about 257,000 tons. Shipments latterly have been heavy. Good orders reported for Black Plate. Liverpool quotations are as follows:

IC Charcoal, Alloway grade	12/ @ 12/6
IC Bessemer Steel, Coke finish	11/3 @ 11/6
IC Siemens " "	11/6 @ 11/9
IC Coke, B. V. grade, 14 x 20	Nominal.
Charcoal Terne, Dean grade	10/3 @ 10/6

Sheet Iron.—Some good sized orders have been placed for Black Sheets, and others are said to be in prospect. The mills are reported as being well supplied with work, some of them for as long as 60 days ahead. Jobbers, however, complain of an absence of life in this line of trade, the fact being that the tendency to purchase even small quantities of Sheet Iron direct from the mill instead of through the dealer is becoming more pronounced, Both in Black and Galvanized Iron there is, at present rates, but a very slim profit for the jobbers, many of whom delare they would sooner not handle the material at all. A very active demand exists for Black Iron of light gauge for trimming purposes. Galvanized Iron moves somewhat heavily. Prices are, however, fairly well maintained. Some good export orders for Galvanized Sheets for Cuba have been lately filled.

Aluminum.—A reduction has been made in the price of Ingot Metal in ton lots from 55¢ to 50¢ ℔ lb for No. 2 grade, and from 60¢ to 55¢ for No. 1 grade. The base price of Aluminum Sheet has been reduced from 90¢ to 80¢ ℔ lb; Aluminum Wire Rods from $1.20 to 90¢ ℔ lb, and Nos. 9 to 14 gauge Wire from $1 25 to $1 ℔ lb.

Chicago Report.

Scrap.—Transactions are very limited. Dealers furnish the following list of buying prices, Chicago delivery:

	Per net ton.	Per lb
No. 1 Wrought Scrap	$7.00	....
Machinery Cast	6.00	....
Malleable Cast	5.00	....
Stove Plate (free of burnt)	4.00	....
Burnt Iron and Grate Bars	3.00	....
Sheet Iron and Hoops	2.00	....
Plow Steel and Breaking Stock	4.00	....

The Sheet Iron Trade.

The coal miners' strike has proved a source of great trouble and annoyance to rolling mill operators and other manufacturers throughout Ohio. When the strike was announced every manufacturer did everything possible to secure a supply of coal and some were successful. Among the number, and probably the most fortunate, is the Cambridge Rolling Mill Company. This concern own their own coal mine, and in consequence now have several thousand tons in sight. At Bridgeport natural gas has been resorted to, although a strong effort was made to induce the Ætna Standard miners to go in at an increased rate of wages. Other mills have moderate supplies on hand which they are using very carefully, running only the finishing departments by using up accumulated stocks of partly finished material. This trouble brings to notice once more the wonderful vitality of the sheet iron end of the rolling mill industry. As soon as mills commenced to shut down, buyers of sheets, particularly roofers, were on the road looking for a place that could supply immediate wants, and with few exceptions large consumers of sheets are asking for quicker deliveries. Several mills have sold their products up to July 1 and others can see enough business in sight to keep things moving until that time.

The little spurt of business among iron and steel roofing concerns which was referred to recently is now confirmed. The best proof of this is that roofers' stocks are running lower than they have during many months.

The Bellefonte Boiler Works, W. T. Maitland, proprietor, is the subject of an extended notice in a recently issued industrial edition of the *Keystone Gazette* of Bellefonte, Pa. The specialty of this enterprise is the manufacture and repair of all kinds of steam boilers, stacks, tanks and sheet iron work generally.

E. C Stearns & Co., Syracuse, N.Y., in connection with their plant, in which a large variety of goods are manufactured, have a large foundry equipped in the best manner and are in excellent position to furnish Gray Iron Castings for other manufacturers.

CONDITION OF THE

Hardware Trade.

DURING APRIL the demand was somewhat spasmodic and uneven. The month opened with trade that was somewhat disappointing, but the last half of the month showed a perceptible improvement. On the whole the aggregate of business was fair. May opens without any special change in the general situation, a good many orders coming in from the trade, but mostly for small quantities. In the matter of prices the market continues weak, although it is a question whether or not in many lines the bottom has been reached. The low price of raw material, the reductions which have been made in wages, and the economies to which manufacturers resort in the production of their goods, have the effect of diminishing costs to a point considerably below that of former years, and the desire on the part of manufacturers to keep their works in operation has the effect of inducing them to make such concessions in prices as will enable them to market their goods. There is consequently in many lines a gradual shading of quotations. This is not confined to manufacturers, but the jobbers also desiring to hold their trade and dispose of their stocks are offering inducements in the way of low prices. The fact that many retailers who are careful buyers are purchasing in unusual y small quantities prevents them doubtless in many instances from obtaining as low quotations as are within their reach. The probable duration and effect of the coal strike is being regarded by the trade with much interest, and its effect is already slightly felt on some goods which lie near the raw material, inasmuch as it induces an element of uncertainty, in view of the fact that if long continued it would produce a scarcity of fuel and cause the shutting down of works. Some manufacturers are therefore disposed to ask slightly advanced prices on some lines, but the trade are not as yet disposed to pay any increased price. The general anticipation is that May will be characterized by a fair but not heavy trade.

Advices from Chicago.—Now that April has ended and a comparison of the volume of business in Shelf Hardware can be made, it is found that the aggregate for the month was but a trifle under that of March. The early part of April was a quiet period, but business picked up considerably during the latter half, which accounts for the excellent showing now made, and yet the condition of business in Shelf Hardware is by no means what it should be. In some cases this spring it has been necessary to considerably decrease the force of salesmen. Wire Cloth has firmed up during the week, and jobbers are now trying to get $1.50. Prominent manufacturers are withdrawing all quotations. Jobbers further West are advising the Chicago trade that they are prepared to follow their lead in putting prices up. Heavy Hardware shows no special improvement, but fair inquiry is noted for Carriage Makers' Supplies. This branch of trade is in a different condition from previous seasons. Contracts are usually placed early in the year by carriage manufacturers, but this season they have not done so, and consequently they are purchasing stock steadily from week to week.

Notes on Prices.

Wire Nails.—The market is scarcely as active as it has been, but there is still a good demand. In the matter of prices there is a somewhat improved tone, and manufacturers are disposed to withdraw some of their extreme quotations, particularly on the ground of the uncertainty as to the duration and effect of the coal strike. On the whole, however, the market remains in substantially the same condition as at our last report, being represented by the quotation of 95 cents for carload lots at factory, a figure which still can probably be shaded. Small lots from store in New York are held at $1.15 to $1.25.

Advices from Chicago.—The early part of last week prices were in a seriously demoralized condition. Some manufacturers became apprehensive as stocks slid up in their warehouses, and they made strenuous efforts to unload them. Later in the week, however, the situation changed materially. The coal famine began to have its effect, and when it was seen that some of the largest concerns would very shortly be obliged to shut down for lack of fuel the Nails in warehouses began to look more valuable. Prices have consequently stiffened, and, as usual when this takes place, inquiries become larger and specifications on old orders came in more freely. Quotations on factory lots now range from $1.05 to $1.10, Chicago, and if the coal strike does not soon end they will go higher. Stocks in dealers' hands have been pretty well run down, and are in such condition now that an advance by manufacturers will immediately be responded to by the jobbers, who for the present are quoting small lots from stock at $1.10 to $1.15.

Cut Nails.—There continues to be a fair but not heavy demand for Cut Nails, and the market, on the whole, is in about the same condition as last week. The Eastern mills are holding up prices pretty steadily, the principal disturbing factor being the entrance into Eastern territory of Western Nails, which are being offered and to some extent sold in Baltimore, New York, Philadelphia and other points through the Middle States. The Western price is represented in a general way by the quotation of 90 cents for carload lots at mill, but this is shaded 5 cents and in some cases more, especially when placing Nails in Eastern territory. The price of Nails delivered in New York is 95 cents to $1 base, small lots from store being quoted regularly at $1.10 to $1.15.

Advices from Chicago.—Manufacturers report a falling off in orders since last report and some weakness in price, owing to competition from factories in other districts. The local makers continue to quote factory lots on a basis of 95 cents, Chicago, for 55 cent average. Jobbers are holding small lots from stock at $1.05 to $1.10.

Barb Wire.—There is a perceptible falling off in the demand for Barb Wire. There is, however, a fair business still doing. The irregularities in price to which we have referred still continue, and while the market is represented by the following quotations for Four Point Galvanized, delivered at the points named, it is not unlikely that they could be shaded: Pittsburgh, $2.05 to $2.15; Cleveland, $2.10 to $2 20; Cincinnati or Allentown, $2.15 to $2.25; Chicago or New York, $2.20 to $2.30.

Advices from Chicago.—Manufacturers report a very good condition of business with some sections of the West, which keeps their order books in fair shape. The demand is particularly good from the Southwest. Business latterly has picked up to some extent with the Northwest, but orders from this section have seldom exceeded carload lots, being mainly for lots of two to three tons. Prices are unchanged at about $2.15, Chicago, for factory lots of Galvanized Barb Wire and $2.30 to $2.40 for small lots from jobbers' stock.

Plain Market Wire.—A fair but not especially heavy business is being done in Plain Market Wire, and prices continue as they have been for some time, low and somewhat uneven, the competition between the mills being active. Base sizes are being sold at $1.30, f.o.b. mill, with proportionate advances for the small sizes. Galvanized is regularly quoted from ½ to ¾ cent advance, but in some cases it is bought at $\frac{4}{10}$ cent advance, there being an apparent tendency to diminish the extra.

Hawthorne Julep Strainer.—Manning, Bowman & Co., Meriden, Conn., are putting on the market this Strainer, which is sold to the trade at $8 per dozen, subject to a discount of 25 per cent.

Adjustable Bathtub Seat.—This Seat is put on the market by the St. Louis Bronze & Aluminum Works, St. Louis, by whom it is sold from the following list, subject to a discount of 35 per cent. to the trade:

No. 1, nickel plated, ash wood bottom with oil finish	$3.50
No. 2, black enameled	2.50

Columbian Screw Plate.—This article is put on the market by Alfred Ely & Co., Baltimore, Md. The discount to the trade on the Screw Plate is 33⅓ per cent.

Simplex Cork Puller.—The Simplex Cork Puller, manufactured by Manning, Bowman & Co., Meriden, Conn., is sold at $31 per dozen, subject to a discount of 25 per cent. to the trade.

Cordage.—There are rumors of some changes in the management of the United States Cordage Company, and of other negotiations looking to the securing of harmony in Cordage interests. As a result of this and other influences the market is firmer and a slight advance has been made in price. The market is now represented by the quotation of 6½ cents for Manila and 4½ cents for Sisal in large lots, f.o.b. factory or New York, subject to the cash discount of 1½ per cent. The trade are placing their orders more freely than for some time in view of the possibility of still higher prices.

Glass.—Prices and conditions in the Glass market remain without change as reported last week. There appears to be no scarcity of the smaller sizes of Glass, but enough to carry the trade until fall. Desirable sizes of larger Glass, it is understood, are sought after, and the lack of sufficient quantity to supply future demand may ultimately result in a larger use of Plate Glass as a substitute. It is reported that the factories in operation represent a capacity equivalent to 1054 pots, which shows an increase of about 50 pots during the past month. Pittsburgh prices are reported as follows: In small quantities by jobbers, single strength, 80 and 10 per cent.; double strength, 80 and 10 and 5 per cent. discount. Factory prices are given as 85 per cent. discount for single and 85 and 10 per cent. discount for double strength Glass. Plate Glass remains firm at 70 and 10 per cent. discount.

Old Metals.—Old Metals are not in quite as good demand as they were a

week or two ago. Inquiries are moderate, but enough business is done, particularly in certain descriptions of Scrap Iron, to keep prices fairly steady. The following quotations represent about the present dealers' buying prices in this city:

Heavy Copper	℔ lb		7½¢
Light and Tinned Copper	℔ lb		6½¢
Heavy Brass	℔ lb		5½¢
Light Brass	℔ lb		4½¢
Lead	℔ lb		3¢
Tea Lead	℔ lb		2¢
Zinc	℔ lb		2¾¢
No. 1 Pewter	℔ lb		14¢
No. 2 Pewter	℔ lb		7¢
Wrought Scrap Iron, ℔ gross ton	$9.00	@	....
Heavy Cast Scrap, ℔ gross ton	7.00	@	....
Stove Plate Scrap, ℔ gross ton	4.50	@	....
Burnt Iron, ℔ gross ton	3.00	@	3.50

Old Rags, Paper, &c.—The market for Paper stock is moderately active, but prices remain at their former level. The following are the ruling prices, New York delivery:

No. 1 White Rags	℔ lb	3¼ @	3½¢
No. 2 White Rags	℔ lb	2 @	2¼¢
Mixed Rags	℔ lb		3¼¢
Blues and 3ds	℔ lb	1 @	1¼¢
Hard Sized White Shavings	℔ lb	2¼ @	2½¢
No. 1 White Book Shavings	℔ lb	1½ @	1¾¢
No. 2 White Book Shavings	℔ lb	1 @	1½¢
Light Book Shavings	℔ lb		¾¢
No. 1 Mixed Shavings	℔ lb	¾ @	1 ¢
No. 2 Mixed Shavings	℔ lb	½ @	¾¢
No. 1 Printed Books	℔ lb	1 @	1¼¢

Jute Butts	℔ lb	1⅞ @	2 ¢
No. 1 Jute Bagging	℔ lb	1 @	1¼¢
Mixed Bagging	℔ lb	¾ @	1 ¢
No. 2 Bagging	℔ lb	½ @	¾¢
Hemp Twine	℔ lb	2 @	2¼¢
Manila Rope	℔ lb	2⅛ @	2¼¢
Jute Rope	℔ lb	1½ @	1¾¢
Mixed Rope	℔ lb	¾ @	⅞¢

Old Rubber.—The market for Old Rubber is fairly active. Prices rule about as follows, but are subject to variation and are somewhat irregular:

Car Springs, ton lots, ℔ lb.	....	@	$0.03½
Rubber Shoes, carloads, delivered at factory, ℔ lb.	....	@	.03½
Rubber shoes, less than carloads, ℔ lb.		@	.03¾
Large Hose, ℔ ton	....	@	12.00
White Wringer Rolls, ℔ lb.	....	@	.03⅜
White Syringes, ℔ lb		@	.03⅝

Trade Notes.

Metcalf & Morrison, 126 and 128 Polk street, Newark, N. J, are a new firm of iron founders making both light and heavy Castings for the trade in the foundry formerly occupied by Rupp & Son.

Under date of April 13 Randall & Becton, 110 Boylston street, Boston, Mass., manufacturers of the Merrill Aluminum Heater, notify the trade that Wm. H. Goss retires from the firm and is succeeded by R J. Gordon.

The advertisement of the Excelsior Steel Furnace Company of Chicago which appears in this issue treats of the subject of Boots. The company manufacture Boots of all sizes and all kinds for use at the bottoms of furnace stacks. Those who take the trouble to clip the coupon in the advertisement will find it worth $1 to them on their first order for such goods amounting to $10 or more.

The Springfield Coil Boiler Company, 48 Hampden street, Springfield, Mass., in an announcement elsewhere in this issue direct attention to the Springfield Coil Boiler of their manufacture. The apparatus is shown brick set, and also with casing removed, so its construction is readily understood.

Avery Stamping Company, Cleveland, with their extensive and well equipped plant, advise us that they are in a position to do all kinds of Tinning and Retinning of Steel or Copper and, in fact, all metals. The company will be pleased to furnish estimates to any one desiring to have Tinning or Retinning work done in large quantities.

The Fair Haven Marble & Marbleized Slate Company, Fair Haven, Vt., have a card in our advertising columns this week directing attention to Slate in all forms for plumbers' use, such as urinal stalls, sinks, closet slabs, basin slabs, &c.

The announcement elsewhere of Savill, Walla & Co., 1229 Budden street, Philadelphia, Pa., will be of interest to the plumbing trade, as it directs attention to Savill's Closet Connection for new, old or broken closets.

The page announcement of the Iron Clad Mfg. Company of 22–24 Cliff street, New York, is of more than usual attractiveness this issue. It tells of the Iron Clad Enameled Ware, the merits it possesses and the popularity it has won, and the illustration is a picture of a train of freight cars loaded with Iron Clad goods made for the Fair. An entire train load of such articles means an enormous quantity for a single shipment.

The advertisement elsewhere of John A. Scollay, 72, 74 and 76 Myrtle avenue, Brooklyn, N. Y., directs attention to the Scollay Hot Water Heater of his manufacture, and points out the purposes to which it is specially adapted.

The Security Gas & Vapor Stove Company, St. Louis, Mo., in an announcement elsewhere call attention to the merits of the Security Gas Range, which is described as new in construction and new in design.

S. Blumenthal & Co., Thirty-eighth street and Eighth avenue, New York, are making a specialty of the Kernan furnace, made by the Kernan Furnace Company, Utica, N. Y. They report a good business and very satisfactory results from the furnaces in use during the past winter.

The Petereit Mfg. Company have been incorporated in New York State, with a capital of $5000, to manufacture metal and other goods in New York City. The directors are: Albert H. Petereit of New York City, Olin F. Gleason of Arlington, N. J., and Doane N. Gleason of Brooklyn.

The present week witnesses the trials of the first two war vessels built at American navy yards for many years. These are the second class battle ships "Maine" and "Texas," the first named built at New York and the latter at Norfolk. The "Maine" will undergo her official horse-power trial and the "Texas" the dock trial of her engines. Both these vessels are built to develop 8500 horse-power, which, it is calculated, should give them an average speed of at least 15 knots an hour. It is not expected that the "Maine" and "Texas" will be ready for active service much before the end of the year.

It Is Reported—

California.

That Fred. Barcoft's Hardware store at MADERA was destroyed by fire on the 20th ult.

Illinois.

That Charles Weber of MILLINGTON is erecting a two-story building which, on completion, will be occupied by his Hardware business.

That Willis & Bender, at LEE CENTER, have disposed of their Hardware store to Harvey Hulbert, who will continue the business at the old stand.

That the store of William Houseworth, MASON CITY, is now being conducted by Paul Enlows, who has purchased the business.

Indiana.

That Sumner & Heffner's Hardware store, at HILLSBORO, was entered by thieves on the 19th ult., but little of value was secured.

Iowa.

That Charles Betler is considering the advisability of opening a Hardware store at PRAIRIE CITY.

Kansas.

That J. C. Guinn, GREAT BEND, has disposed of his stock of Hardware to I. N. Woodward.

That George Smies has purchased an interest in the Hardware business of Keener Bros., CLAY CENTER, and hereafter the firm will be known as the Keener Bros. Hardware Company.

Massachusetts.

That in a large fire at MARLBORO on the 25th ult., the store of W. H. Hill suffered damage to the extent of $2500.

That E. A. Buck & Co., dealers in Hardware, &c., PALMER, are to move into larger quarters about July 1.

That J. R. Todd & Co., WARREN, who recently purchased the Stove and Tin store of W. A. Putnam, have given up the business and removed to Natick.

That a two-story storehouse is being built at NORTH ADAMS, which on completion will be occupied by J. M. Darby.

Michigan.

That Jilbert & Lang have opened their new Hardware store at HOUGHTON. A tin shop will be run in connection with the store. Mr. Jilbert will manage the business. He was formerly connected with the firm of Mondlock & Yagle of HANCOCK and also with J. Pearce at DOLLAR BAY.

That the store of the Phillips Hardware Company, at BLISSFIELD, was burned out on the 23d ult. The loss is estimated at $1500.

Minnesota.

That thieves entered K. Anderson's Hardware store, at LAKE BENTON, on the 18th ult., and carried off a small quantity of Firearms and Knives.

That James Becker has purchased the Hardware stock of Wm. Thoman of HOKAH.

That a partnership has been formed between C. A. Smart and Frank Butler in the Hardware business at AUSTIN.

That the Hardware firm of Clark & James, at ORTONVILLE, have dissolved. Mr. James will continue.

That Mr. Johnson, in the Hardware business at WYKOFF, has sold out to Mr. Boyer of FOUNTAIN.

That Phelps & Co. have succeeded Byron D. Wilson, Hardware merchant, at EXCELSIOR.

That the Martin Company, Hardware merchants, YOUNG AMERICA, are going out of business.

That Heogh & Qually are successors to Charles Heogh at SPRING GROVE.

That Lord & Pokornosky are conducting the business formerly carried on by Jno. Pokornosky at SILVER LAKE.

That Bryant & Andrews, Hardware dealers, MONTICELLO, have sold out to M. B. Bryant.

Missouri.

That J. H. Bockhorst, ST. LOUIS, has removed from 1324 Franklin avenue to 1220 Franklin avenue, where he has a much larger and more convenient store.

That E. Bueltman, ST. LOUIS, has repurchased his old Hardware and House Furnishing Goods store located at Fifteenth and Monroe streets.

Montana.

That the Bee Hive Hardware Company of DILLON have sold out to G. W. Dart.

Nebraska.

That Harrington Bros. Hardware store, at PAWNEE CITY, was burglarized of $60 worth of goods on the 16th ult.

That Taylor Bros. of MINDEN have opened a new Hardware store at TRUMBULL.

New York.

That George S. Pierson & Son of CORNING have disposed of their Hardware store to James Kiff of COVINGTON.

North Dakota.

That F. C. Walter, dealer in Hardware at MINTO, is disposing of his business.

Natural Gas Consumption.

The annual report of Special Agent Joseph D. Weeks of the United States Geological Survey for the year 1893 discloses the fact of the growing confinement of the consumption of natural gas to domestic use. The only State in which the use of natural gas for manufacturing purposes increased last year is Indiana. This State contains by far the most important gas field, its estimated area of productive gas territory being about 2500 square miles. Moreover, while the supply falls far below the demand in other gas fields, it is stated to be well maintained in Indiana, and supplies are even obtained from thence by factories in other gas territories. The value of the product consumed in Indiana in 1893 was $5,718,000, against $4,716,000 in 1892. The total value of natural gas consumed in all parts of the country last year was $14,346,250, as compared with $14,800,714 in 1892. This decrease is attributed to the higher prices charged for the gas in 1893. The falling off in value of the gas consumed has been steady since 1888—the banner year—when $22,629,875 worth of the fuel was used. Of this output Pennsylvania alone produced the value of $19,282,375. Last year the output of that State had sunk to $6,488,000, and all the other States, except Indiana, showed a like decline.

The Spread of Sanitary Legislation.

The wave of sanitary legislation that is sweeping over the United States is a most encouraging and excellent sign of the times. A few years ago it would not have been thought possible that so many cities would so soon have adopted measures regulating the plumbing and sanitation of houses. Of course, there have been rules governing this work in the principal cities for some years past, and it is not to the spread of such laws among the cities of the first magnitude that we allude. It is the permeation of the spirit of sanitary reform into the small cities and towns throughout the entire country that awakens surprise and admiration. In fact, so general has been the adoption of laws of this sort that it has been almost impossible to keep track of the places that have followed in this line of reform. It is natural to ask the cause of this sanitary revolution which has been so wide sweeping, and we think it will be generally admitted that the body largely responsible for the good work is the Master Plumbers' Association of the United States, acting upon legislators through the various local associations. For this work they cannot be too highly praised; and it is evident that, with the still further spread of the organization among smaller towns and remoter parts of the country, there will be a corresponding spread of sanitary legislation that will conduce to the health, happiness and material welfare of all people. If the Master Plumbers' Association should come to an end to-morrow it would not have existed in vain, for the impetus that has been given to reform along this line would be felt for years to come. The association, however, is too robust and great a body to fear any sudden death; and we believe that with its growing strength it will increase in usefulness in this as well as in other work.

Sensible Stove Manufacturers.

The stove manufacturers conduct their business very differently from their colleagues in other branches of the iron trade. While prices generally have been not merely reduced but savagely cut until not a semblance of profit can be detected in most staple articles of iron and steel, the manufacturers of stoves have refused to be stampeded and have maintained their schedules. They have seen the demand for their goods shrink steadily 10, 20 and even 30 or more per cent. below their customary volume of business, but have not sought to stimulate the drooping trade by offering stoves at lower and lower prices. In recent years margins of profit have been very slight, owing to increasing competition, and it would have been supposed that the competition for business would be more severe than ever when trade fell off. Yet this was not the case. Conservatism and philosophy ruled in the councils of the stovemen instead of blind frenzy and a rash desire to keep selling. When they found their warehouses getting uncomfortably full of stoves which could not be sold they shut down their foundries and waited for trade to improve. From time to time, as their stocks were drawn upon by the requirements of the trade, they resumed work in the foundries.

Wages Maintained.

Thus has the stove business gone forward, not by any means to the satisfaction of the makers, but with far less friction than in many other lines. Workmen employed in the foundries have not struck because they had no incentive to strike, as their wages were not reduced nor has a reduction been even threatened. Stocks of stoves in dealers' hands have suffered no depreciation in value through the action of the manufacturers, which can hardly be said of any other goods carried by them. The fact seems to have been universally recognized that stoves are cheap enough and sold at figures sufficiently close, so that reductions in price if made would not have enlarged the consumption. It is doubtful if a single consumer who needed a stove during this panicky period made an argument for a lower price based on the decline in other goods. In fact, the reductions in prices on such goods have not been made to any extent in compliance with the views of consumers, but have almost wholly been brought about by the action of the manufacturers themselves. The stove manufacturers propose to continue this policy. At their recent convention in Chicago they passed a resolution that in view of the decreased demand for stoves and the maintenance of the old scale of wages paid their workmen, which had materially enhanced the cost of production, making the selling price so nearly approach the cost, a rigid adherence was obviously required to existing prices and terms, and that it was the sense of the convention that such prices and terms should be firmly maintained during the year 1894. The manufacturers are undoubtedly of the opinion that the depression in business is only temporary, and they seek to prevent a demoralization in their trade and disaffection among their workmen which might not only lead to serious consequences now, but be felt injuriously for some time after the depression passes away.

Prices Maintained.

It is worthy of note in this connection that the stove manufacturers have been able to maintain their prices without the formation of a trust or a combination, or even the semblance of one. They have two national associations, one for defense in case of labor troubles and the other for the mutual interchange of ideas on subjects connected with their business as manufacturers. Neither of these, however, regulates prices. And yet, with no machinery whatever in operation to bolster up one another, they maintain their rates against adverse circumstances which have wrecked combinations of almost every kind. They are a shining example for other manufacturers who have steadily parted with every advantage given them in reducing costs, as if they were in business only for the benefit of the dealer and the consumer.

THE LETTER BOX.

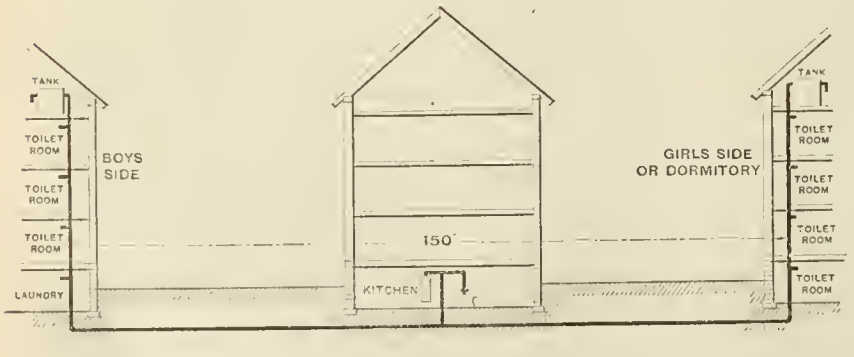
Expanding Liquid.

From C. W., *Winnipeg, Man.*—Will *The Metal Worker* or some of its readers inform me of a liquid that will not harm metals which will contract considerably between 34° and 32° above zero?

Answer.—Our correspondent is probably familiar with the peculiar properties of water, whose point of maximum density is about 39° F. From there to the point of freezing, as the temperature falls, the liquid expands. Water, however, is the only fluid that has a point of maximum density higher than the freezing point. The liquid most suitable to our correspondent's needs is, we think, alcohol, which is one of the most expandible of common fluids. Between 32° and 212° F. its volume increases about one-ninth; under the same conditions mercury expands one sixty-fifth of its volume. Nitric acid has the same percentage of increase as alcohol, namely, one ninth, but, of course, it would be inapplicable to our correspondent's use, on account of its corrosive effect on metals. Our correspondent will realize that if he wishes to make the fluid visible it is easy to color it.

Erratic Water Supply.

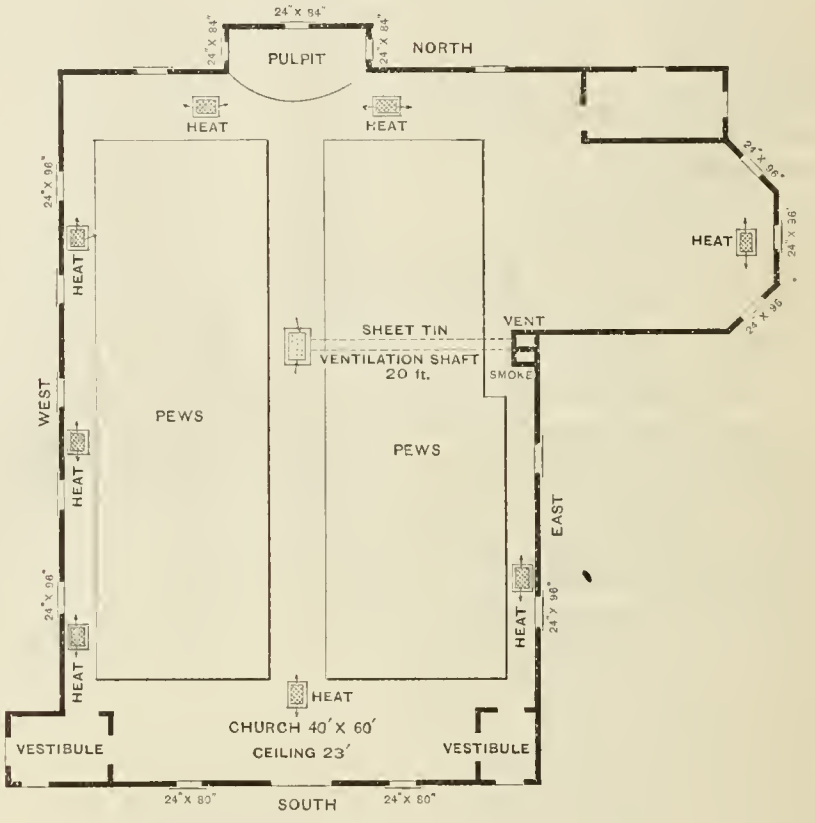
From G. E. S., *East Stroudsburg, Pa*—I have frequently noticed the trouble that is reported with the flow of water through pipe in different parts of the country, and I now have a mystery on hand which I cannot explain. The sketch shows two different buildings which are supplied with water from the street main. There is a 1000 gallon tank in the upper part of each of the buildings, which are 150 feet apart and connected with a 2-inch supply pipe to which is attached a float valve. When the supply to the tank in the boys' dormitory is closed we have no trouble to draw all the water needed in the laundry and all the toilet rooms, but when the water is closed off in the dormitory on the girls' side there is trouble to get a flow of water in the tank on the boys' side, the supply barely reaching the third story. There is much more water used in the laundry than in any of the other buildings. This experience shows that the water flows much more easily to one dormitory than it does to the other, yet when the school was first opened it worked equally well on either side. I shou'd like to have the readers express their opinion as to what makes the trouble.



Erratic Water Supply.

Wants a Better System.

From W. S. G., *Penbrook, Pa*—I send herewith the drawings for a church that is to be built in this town. The church in question is 40 x 60 feet with ceiling 23 feet high, built of brick and stone with all sides exposed and on a slight elevation of ground facing south. The architect has made a few marks relative to location of registers, &c., on the floor plan as a guide for the heating



Wants a Better System.

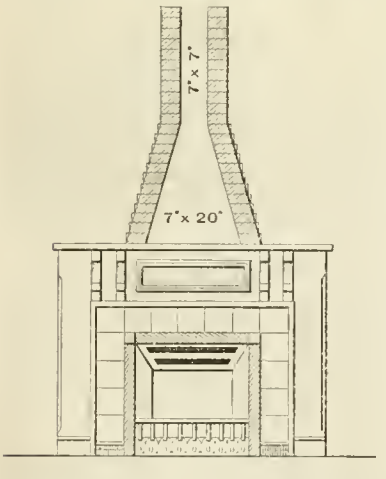
engineer of what he calls a practical system of ventilation. His theory is that the hot air will rise at the outer edge of the room and concentrate at the ventilating register, which is in the center of the room, drive out the cold and stagnant air through the vent shaft, which is almost as cold as icy Greenland, and furthermore the draft of the shaft will also assist in carrying off the cold air. The furnaces take the fresh air from the cellar, which is a grand feature, as church cellars, generally speaking, are in a haphazard condition, containing an accumulation of ashes and other refuse which laden the air with impurities which are taken into the furnace, thence into the church room and into the lungs of the occupants, causing more or less distress. If the furnaces, are put in according to this plan the result would be a warm ceiling and a cold floor, with a large percentage of loss of heat through friction and radiation in the cellar. There would be no circulation of air which is essential to perfect heating. Another barrier to the perfect operation of the furnaces is the chimney, which is lower than the ridge of the roof, causing rebounding currents of air to take place at intervals, a detriment to the working of the furnace. My plan would be to pour the heat into the room in an

undivided volume, and so maintain its power and quicken the ascent to the room above with less loss of heat through friction and radiation. Now I want some of the practical readers of *The Metal Worker* to give me a plan to heat this church in a satisfactory manner under existing circumstances by hot air without respect to the architect's or my opinion.

Note.—We hope this correspondent will not be disappointed in his appeal for assistance. It would seem that as the ventilating shaft is warmed on one side by the smoke flue there would be a tendency for upward currents in it. Many churches are heated with air taken from the cellar, but it has been suggested that an arrangement for taking the air from either the church or out of doors at will has advantages. Some authorities agree with our correspondent that it is better to have one large register over the furnace than to have several scattered registers. Here is an opportunity for giving a rule for determining the size of register, ventilating shaft and air supply, as well as suggesting a method of heating.

Fire Place Smokes.

From J. A. S., *Fairfield, Iowa.*—I was much interested in the article on the proportion of fire places in *The Metal Worker* of April 7. It is a fact that half of the grates in this town smoke, and some of them that have the smallest flues work the best, so that I think it is not so much the size of the flue as the way the grate is connected to the flue and the shape of the flue at the grate connection that causes the trouble. The question is, How ought the grate to be connected with the flue and what should be the size of the opening that leads to the flue to make a good draft for soft coal or wood? For an ordinary sized fire place which has a front opening 24 x 30 or 30 x 30 inches, what is the best proportion or



Fire Place Smokes.—Fig. 1.—Front View Showing Flue.

shape for the opening to the flue? Should the opening be over the front or the back part of the grate? I inclose a drawing of a grate that is located in the corner of a room which has about 1 foot of space between the back of the grate and the flue. Fig. 1 shows a front view of the grate and the shape of the flue over it. Fig. 2 shows a sectional view of the grate and the opening space behind the grate. This grate smokes when burning either wood or coal, and I would be under obligations to some reader of *The Metal Worker*

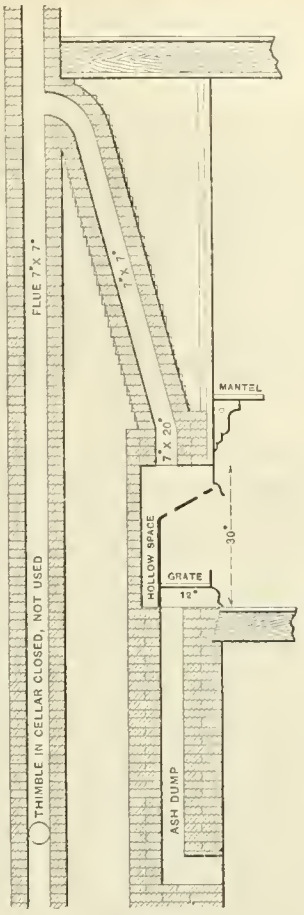


Fig. 2.—Sectional View.

who can suggest a way to make it work well without smoking. As will be seen by the sketches, the smoke flue is 7 x 7, and at the top of the grate it is 7 x 20 and gradually tapers into the flue above.

Machine or Tool?

From M. J. C., *Elwood, Ind.*—Will the readers of *The Metal Worker* please state whether a lathe should be classed under the head of tool or machine in the stock account of a foundry and machine shop? The question has been raised in our office, and some think that the lathe should be considered under the head of a tool, claiming that it is a machine tool, and for that reason should be called a tool.

Note—As this question is an interesting one, we hope to receive reports of the custom observed in different offices on the classification of this fixture in their plants.

How He Uses His Paper.

From C. E. S., *Clinton, Iowa.*—I have read *The Metal Worker* with great interest for a number of years, and as the copies do not come fast enough I frequently read much of the valuable matter they contain a second time, particularly during the winter months. As a result of my reading I have devised the following method of preserving them. I separate the advertising pages from the reading matter and bind six months of the reading matter together, as a larger volume is inconvenient to handle, and in this way it is ready for reference. I then sort the advertisements, preserving one of every advertisement that has appeared, and bind this as a separate volume, which makes a most excellent buying directory. I would advise others to follow this plan, as they will find it very useful, and they can readily do it themselves. To me the Letter Box is a very interesting feature, and I use it as a sort of civil service examination, reading every question and preparing a satisfactory answer, at least to myself, and whenever I am unable to answer a question I make it a point to seek for the information until I find it.

Centennial Flat Iron Heater.

From W. H. HESS, *Lanark, Ill.*—Will some reader of *The Metal Worker* furnish me the address of the manufacturers or sales agent of the "Centennial Flat Iron Heater," a round heater made to set in a single lid opening of an ordinary cook stove? The heater has a pair of sliding covers that close automatically when the iron is placed in the heater. No manufacturer's name appears on the heater, but it is marked "Patent Allowed 1876." I am anxious to obtain this information and will be much indebted to any one who can furnish it.

The World's Fair Buildings.

The Columbian Exposition Salvage Company, with a capital of $200,000, have purchased the 20 World's Fair buildings, which are all the buildings that the Park Commissioners had in their possession, with exception of La Rabida Convent and the Forestry Building, for the sum of $80,000. This gives them a working capital of $120,000 after paying for the buildings. The company consist of the following scrap iron and scrap metal merchants: August Pollak, North Western Iron & Metal Company of Chicago, Ill., A. S. Deutsch & Co., of Chicago and Cleveland, and Ohio Iron & Metal Company of Cleveland, Ohio, and the Chicago House Wrecking Company of Chicago, and Sievers & Fearnly of Cincinnati, Ohio, who are experts in the business of dismantling houses and buildings and also large dealers in the lumber trade. It is expected that work will begin within a few days. The end of this season will see the White City pretty well dismantled. All the structural material will be taken down very carefully, and the company are prepared to sell to railroad companies, factories and others who contemplate erecting buildings any quantity of such material in the iron and lumber structural line that they desire.

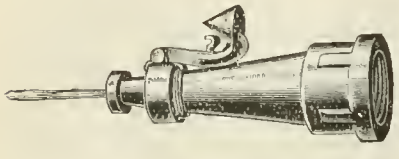
Returns of the mineral production of Canada for the year 1893 have just been issued. They show an aggregate value of $19,250,000, or $250,000 less than that of 1892. Nickel heads the list of metals, the output being 3,992,982 tons, valued at $2,078,351. Gold was produced of the value of $927,244; copper, $875,864, and silver, $321,423. The coal mined was 3,000,700 tons, valued at $8 422,259; iron ore is placed at 124,702 tons, valued at $298,018.

The new wheat crop of the Argentine Republic is said to be an abundant one. It is expected that the surplus available for export will be largely in excess of the exportation last year, which amounted to over 1,000,000 tons. The wool clip is also said to be heavy.

THE RETAIL STORE.

Spray Nozzle.

We show in the accompanying illustrations a spray nozzle made by the Ette & Henger Mfg. Company, St. Louis, Mo. Fig. 1 shows the nozzle throwing a solid stream, while Fig. 2 shows it



Spray Nozzle.—Fig. 1—View of Nozzle Throwing Solid Stream.

with the spray attachment. One of the special features to which the manufacturers direct attention is that it has no joints or packing to wear out or leak. The spray attachment, which it will be noticed is hinged, and may be thrown forward in front of the stream, will

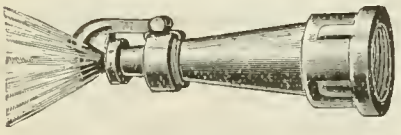


Fig. 2.—View of Nozzle Throwing Spray.

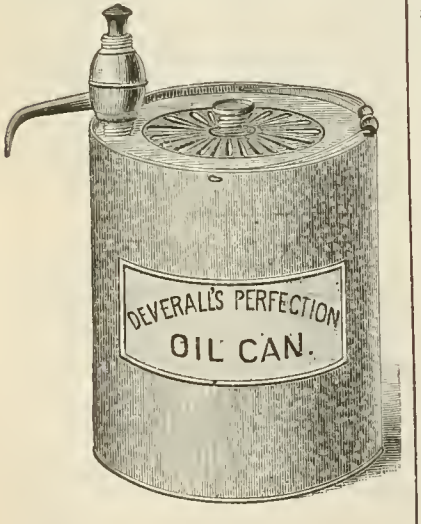
permit of a spray as fine as mist, or will close off the pressure entirely, acting as a cock. The nozzle is made in two sizes, ¾ and 1 inch, both brass and nickel plated.

The Perfection 5-Gallon Can.

Deverall Perfection Mfg. Company, 36-38 Bridge street, Brooklyn, N. Y., are offering 5-gallon oil cans, an illustration of which is given herewith.



The Perfection 5-Gallon Can.

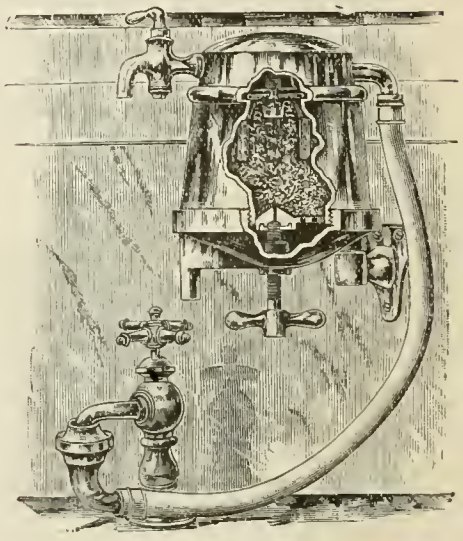
The can is made of No. 28 galvanized iron, with a stamped bottom set up ½ inch and a corrugated tin top. The pump is removable for shipping or when sending the can to be refilled, and is made so that the spout may be swung over the top when not in use. The manufacturers claim that the can has a strongly constructed bottom and top to withstand hard usage; that the can may be perfectly sealed for transportation when filled; that the pump thoroughly vents the can, insuring a perfect flow, and that the pump is simple and strong, provided with anti-corrosive valves. It is stated that the can is well constructed and thoroughly soldered.

Pure Water-Pure Food Filter.

The accompanying illustration shows a filter which the Coles Mfg. Company of Philadelphia are putting on the market. In construction it consists of a brass or iron cylinder with a removable bottom having a discharge nozzle. Three perforated tubes are attached to a plate or diaphragm fitting into a recess or roll around the upper part of the cylinder, through which the water is carried to the center of the filtering material. Another perforated plate or diaphragm fits loosely in the lower rim of the cylinder, and is raised or lowered by a T handle screw passing through the removable bottom. A faucet is placed in the upper part of the cylinder in order that unfiltered water may be drawn when required. Water is supplied to the filter by means of a rubber hose connected to a supply nozzle in the head of the filter and attaching to a supply faucet by means of a special coupling containing a rubber washer with a small hole in its center which allows of a tight connection being made with the nozzle of any ordinary compression or basin cock or spigot. The filtering material used is a cotton pulp which is designed to absorb the sediments, impurities, and coloring matter contained in the water passing through it, and allows the water to pass out through the discharge in a steady stream, it is stated, of 25 to 30 gallons capacity per hour in the smallest size of the filter.

Filtered water is discharged from the outlet at the bottom of the filter, at the left hand side, as shown. By turning the supply faucet with which the filter is connected an immediate flow of filtered water is obtained. When the pulp becomes impregnated with foreign matter, it is taken out of the filter, washed in the same manner as a piece of cotton cloth and replaced. In this way the pulp may be used over and over again without renewal. In the smallest size of the filter it is claimed that from 400 to 800 gallons of water may be filtered without cleansing the pulp. The filter is affixed to a wall or wood work by a bracket which enters a socket in the cylinder bottom, and thus allows of easy removal when required. Adjustment of the filter to the water pressure is obtained by raising or lowering the bottom plate by means of the screw until the pulp presents the necessary compactness to secure thorough filtration with a quick supply. The heavier the water pressure the greater the compactness of pulp required.

The filter is made in two sizes. The cut shows the larger size, made of brass, polished and nickel plated, or of tinned cast iron. The smaller size of filter is made entirely of tinned cast iron, for kitchen or common use, without facilities for securing unfiltered water other than by removal of the filter tube. The filter is also made of special form for permanent attachment. The makers claim that the filter embodies the following advantages: Indestructible filtering material capable of being easily and thoroughly cleansed; thorough and rapid filtration, with little diminution in delivery, and adaptability to any pressure.



Pure Water-Pure Food Filter.

MEMORANDA.

The firm of C. Seybold & Son, Jeannette, Pa., have been succeeded by Nesbitt & Bro., who will carry on the business of dealing in stoves, tinware, &c. Messrs. Seybold are going into the lumber business in Randolph County, W. Va.

Ziegler & Queary and W. W. Prather of Manchester, Ohio, have consolidated and will remove to Portsmouth, Ohio, where they will do business under the style of the Portsmouth Tinware Company as jobbers in tinware, wooden ware, stoves and crockery.

The gold mining industry of Oregon received considerable stimulus last year. It is stated that the gold output for 1893 was nearly $2,000,000, a far larger yield than ever before. Her wheat and woolen interests, however, suffered severely from depression.

The new truck receiving station of the Pennsylvania Railroad, in Jersey City, is of very large dimensions. It is 655 feet long and 92 feet wide. Eighty trucks can unload at once on each side of the platform.

PLUMBING and GAS FITTING.

Plumbers' National Convention.

President Finnerty is sending the following notice to the master plumbers' associations in the different States:

The twelfth annual convention of the National Association of Master Plumbers will convene in Philharmonic Hall, Detroit, Mich., at 10.30 a.m., Tuesday, June 19, 1894, continuing in session for three days. The Cadillac Hotel has been designated as national headquarters. Accommodations can be secured at the above house for from $3 to $4 per day. Accommodations can also be had at the following: Russell House, $2.50 to $3.50; St. Clair Hotel, $2.50 to $3; Normandie Hotel, $2 to $2.50; Wayme Hotel, $2 to $2.50; Barclay Hotel, $2. The above rates are all on the American plan. The houses are all located convenient to Philharmonic Hall, with the first four possessing the advantage in this respect. The Railway Association of Michigan, the Trunk Line Association, the New York & Boston Lines Passenger Committee and the Central Traffic Association have granted excursion rates of a fare and a third on the certificate plan to all delegates and alternates attending the convention, from points within their respective jurisdictions. Each person desiring an excursion rate must purchase a first-class ticket (either limited or unlimited) to Detroit, for which he will pay the regular fare, and upon request the ticket agent will issue a certificate certifying to the purchase of ticket at the regular tariff fare and likewise determining the route via which return ticket will be sold. This certificate must be signed by the ticket agent at the point where the through ticket is purchased, and in the presence of the ticket agent, signed by the purchaser; also, countersigned at the convention by the financial and recording secretary of the National Association of Master Plumbers and viaed by the special agent of the railway association.

Tickets for return journey will be furnished on presentation of the above certificates to the ticket agent at Detroit on payment of one third the regular first-class fare. The return tickets will be furnished only on certificates procured not more than three days before the convention assembles nor later than three days after the convention assembles (June 19), and will be available for continuous passage only, no stop over privileges being allowed on tickets sold at less than regular unlimited fares. The certificates will not be honored unless presented within three days after the adjournment of the convention, Sunday not being reckoned as a day. Certificates are not transferable. No refund of fare can be expected because of failure of parties to obtain certificates and have them properly filled out.

It is to be regretted that the Western Passenger Association has declined to grant a rate of a fare and one-third on the certificate plan; therefore delegates north of the north line of Cook County, Ill, and west of the west line of said county and the Illinois and Mississippi rivers, not including Burlington, Keokuk, Quincy, Hannibal and St. Louis, which cities are in the territory of the Central Traffic Association, will have to pay the regular fare to and from the said cities, but from there they can purchase tickets on the certificate plan as herein described. Delegates from the South outside of the Central Traffic and Trunk Line associations will have to pursue a similar course.

Boston Plumbers and the National Convention.

By addressing National President Daniel G. Finnerty, at 378 Boylston street, Boston, Mass., at an early date arrangements can be made by plumbers along the route to Detroit for joining the Boston delegation. Mr. Finnerty has sent the following to the association in New England, New York, New Jersey and Delaware:

The delegates from Boston and vicinity will leave Boston at 2 o'clock Saturday afternoon, June 16, via Boston & Albany Railroad and New York Central & Hudson River Railroad, arriving in Buffalo at 4 o'clock Sunday morning, and from there proceed to Niagara Falls, where the special train will be side tracked until Sunday noon, thus giving the delegates an excellent opportunity to view the falls. The train will leave Niagara Falls about Sunday noon via Michigan Central Railroad, arriving in Detroit about 9 o'clock Sunday evening. It is hoped that the delegates from the New England States and New York and those who can join the party along the route will do so and stop over with them at Niagara Falls. In order that ample provision may be made for all, it is earnestly requested that those intending to join the Boston delegation and stop over with them at the falls will give notice of their intention as early as possible of the number and where they will join the delegation. The following is a schedule of the train's time at places where delegates can join the delegation:

JUNE 16, 1894.

Train leaves Boston 2.00 p.m.
Train leaves Worcester 3.12 p.m.
Train leaves Palmer 4.17 p.m.
Train leaves Springfield 4.44 p.m.
Train leaves Westfield 5.01 p.m.
Train leaves Pittsfield 6.32 p.m.
Train leaves Chatham 7.16 p.m.
Train leaves Albany 8.10 p.m.
Train leaves Utica 10.35 p.m.
Train leaves Syracuse 12.00 midnight.
Train leaves Rochester 2.10 a.m.
Arrive in Buffalo 4.00 a.m.

The above table is liable to a slight change before June 16. Should such change be made, further notice will be received from this office, or can be had on application to local ticket agents.

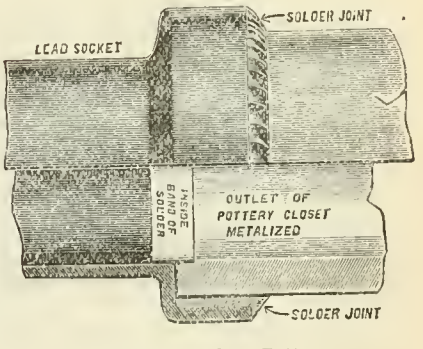
THE ATTENTION of passers by was attracted to the shop of George Franklin, 142 Centre street, New York, last Monday by some quarter bends made of 8-inch pipe from sections 12 feet long. These pipes were for use in a water works system to overcome the friction that would result from the use of the ordinary ells. The bends were very true and smoothly made.

New York Delegates.

Master Plumbers' Association of New York City have elected the following delegates to attend the national convention of the Master Plumbers to be held in Detroit next month: Col. Geo. D. Scott, John Byrns, John Mitchell, H. G. Gabay, H. J. Pattison, Chas Schloesser, Jas. G. Collins, Thos. J. Tuomey, W. M. Young, John Yule, John C. Starck, Wm. Montgomery, M. J. McDermott, E. J. Brady, Jas. Gillroy, Saml. Malcolm, Michael Regan, John McCarren, Jos. W. O'Brien, Frank Reynolds, Timothy Sullivan, Thos. Martin, E. P. Mahoney, Philip Smith, Jas. R. Corbett, Alex. Cameron, Wm. McDermott, Thos. J. Cummings, Adam Huston, Jas. M. Martin, C. Fraser, P. J. Carpenter, J. O. Shumway, Chas. A. Walsh, J. A. Rossman, J. E. Toumey.

Soldering Metal to Pottery.

A new method of connecting lead with porcelain is shown in the engraving below, which is reproduced from



Soldering Metal to Pottery.

London *Engineering*. It has been patented by Doulton & Co., 75a Queen Victoria street, London, E. C. The object of the invention is to get a permanent and tight joint between soil pipes and earthenware plumbing fixtures. The fixtures are made and glazed in the usual way, and the part which is to be connected with the lead pipe is painted over with a metallic solution and then fired. A thin film of metal is thus formed on the surface of the porcelain, and to this the lead pipe can be soldered. It is claimed that the union is perfect; that the lead cannot be removed without tearing the glazed surface of the earthenware, and that the joint is not only air tight, but will resist a strain far greater than it could ever encounter in ordinary usage. The manufacturers state that one was connected with an air pump and tested to 250 pounds on the square inch, a pressure which it sustained perfectly. It is probable, says *Engineering*, that this method of attaching a metal pipe to earthenware will be used for many other purposes besides that for which it has now been introduced, but even should this not be the case, the invention is a very useful one, and will probably supersede red lead and other joints when connecting lead pipes with earthenware.

Massachusetts Master Plumbers.

The Convention of the Massachusetts State Association of Master Plumbers met at Holyoke last Tuesday, nearly 100 delegates attending. A dinner was enjoyed at which Mayor Whitcomb and others were guests. The officers elected for the ensuing year are:

President, W. H. Mitchell, Boston.

Vice-president, J. W. Green, Worcester.

Recording secretary, Daniel Shannon, Boston.

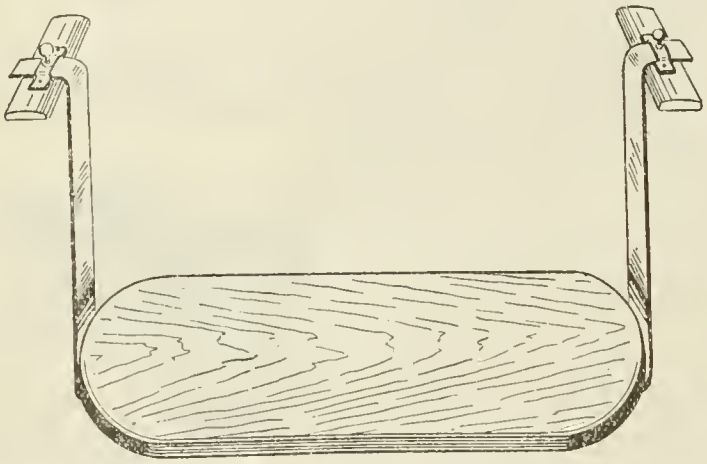
Financial secretary, C. P. Lyman, Holyoke.

Treasurer, E. D. Casey, Holyoke.

Executive committee, J. W. French, Boston; T. J. Clifford, New Bedford; R. E. Fogwell, Fall River; J. F. Davelin, Somerville; O. S. Kendall, Worcester.

Adjustable Bathtub Seat.

St. Louis Bronze & Aluminum Works, 3741–3743 North Broadway, St. Louis, Mo., are offering an adjustable bathtub seat, as shown herewith.



Adjustable Bathtub Seat.

The hanging bar upon which the seat rests is made of polished steel, nickel plated, the clamps are of cast brass, nickel plated, and the seat and bearings of oil finished ash, the bottom of the bearings being covered with rubber so as not to deface the bathtub molding. The seats are also made with the metal work enameled, instead of being finished as described. Other styles are made to order with adjustments on the sides to raise or lower the seat, with a tilting seat board made of any kind of wood desired, or of aluminum or rubber. The seats are designed to fit any style of bathtub and for all kinds of bathing. They are referred to as convenient for foot baths, hip, vapor or sitting baths, and as especially adapted to the use of invalids.

TRAPS AND VENTS.

D. R. Brownlow, plumber, of Middletown, Conn., is placing on the market a new lamp and gas stove with curling iron heater attachment. The stove, we understand, is meeting with an excellent demand from the trade.

"Clean Sweep Non-Syphon Sewer Gas Trap" is the title of a catalogue issued by the Detroit Sanitary Supply Company, Detroit, Mich., sole manufacturers of these devices. The catalogue is addressed to architects, plumbers and all interested in sanitary plumbing, and has been gotten up in a neat and tasteful manner. The Clean Sweep traps are illustrated in all sorts of forms as adapted to lavatories, &c., different forms of traps being illustrated both separately and in connection with fixtures. Brass and lead traps are both shown, and several pages are given to bath wastes and overflows. Basins are shown, and at the close are illustrations of basin plugs. In connection with the illustrations are full price-lists and, where necessary, brief descriptions.

L. M. Barnes of Burlington, Conn., has bought out the plumbing business of the Cowles-Couch Company of Church street, New Britain, Conn. Mr. Barnes is a graduate of the New York Trade School, and has worked several years in Cleveland, Ohio.

The Park & McKay Company, Detroit, Mich., issue a handsome catalogue of the Utopia high grade syphon water closets. The pamphlet, of large size, contains illustrations of the Utopia closets in various finishes and combinations. Altogether, some 24 large pictures of the closet are shown. Full particulars of the finishes and prices of the different combinations are given in connection with the illustrations, while an introductory portion gives a description of the closet, and sectional views show its constructive features and operation.

The annual meeting of the stockholders of the Vanderman Plumbing & Heating Company was held in the office at Willimantic, Conn., on May 2, at which the following directors were chosen: William Vanderman, A. T. Fowler, Dennis Shea, John Riley, E. L. Vanderman. The directors selected A. T. Fowler president, Dennis Shea vice-president, John Riley secretary, Wm. Vanderman treasurer and manager. A 6 per cent. dividend was declared on the capital stock from the earnings of the company during the past year. The amount of business done this year showed a large increase over the preceding year.

The Kelly & Jones Company, Greensburg, Pa., are sending out a circular entitled "Speaking of Air Cocks," showing a weather cock on a building and the air immediately around it filled with air cocks and pet cocks of their manufacture which are provided with wings. On the inner pages, with the statement "Here are a few larger birds of the same feather," they show a variety of the cocks they make. They also make a specialty of recessed fittings for wrought iron drainage systems and issue a small circular showing the different styles of fittings they make, with prices.

The plumbers of San Antonio, Texas, complain because the sanitary regulations of that city are not enforced.

John Bragg, Shelbina, Mo., has bought the business of the Boyd Plumbing Company, at Quincy, Ill., and is now in full charge.

Henry Hauk and Anton Metz have bought out the plumbing business of Edwin C. Mason, at Madison, Wis.

Steadman & Co. have bought the plumbing business of J. W. Skelly & Son, at Bristol, Conn.

John Cremin has been chosen delegate from Pawtucket, R. I., to the national convention of the Master Plumbers' Association of the United States, which occurs next month in Detroit, Mich.

The special brass work required in many of the new and large buildings which have been in course of completion during the past winter has brought many orders for special plumbing fixtures to James Conity, 256 Pearl street, New York.

W. H. Poole has bought out the plumbing business of W. A. Pierce & Co., 126 Main street, Charlestown, Mass.

Secretary J. A. Barr of the Master Plumbers' Association of Rochester, N. Y., informs us that the following delegates to the national convention of the master plumbers to be held at Detroit next month were elected at a recent meeting: J. A. Creelman, J. A. Barr and J. Mahar. Alternates: Thomas Connolly, H. Hart and George Dodds. President W. G. Reed will also attend.

George H. Murphy, 31 Hamilton street, Bound Brook, N. J., is circulating in his locality a circular entitled "That New House," calling special attention to the Auburn steam boiler and explaining that a modern house is not fully equipped without a bathroom and a good plumbing system, and that the house is not habitable unless it has a water tight roof.

The Centre street store of the Colwell Lead Company of New York City, dealers in plumbers' supplies, has been recently improved and adorned by the remodeling of the street front. Large plate glass windows have been inserted and the whole exterior of the well-known establishment at No. 63 has had imparted to it a bright and attractive appearance.

A pleasant letter from J. H. Donnelly of Ware, Mass., states that he is still engaged in business in that city, and that the volume of trade has so increased that he has found it necessary to take larger quarters, at 71 Main street. Through some error, the impression has gone abroad in the trade that he has removed and his mail is being sent to other cities, causing him no end of annoyance.

The Miller Iron Company, Providence, R. I., are sending to the trade a circular relating to cast iron tanks made in two sizes—24 x 72 and 24 inches deep and 24 x 60 and 24 inches deep. They are made with an outlet for connecting either iron or lead pipes

and can be furnished with or without an overflow. The company also make a special style of tank legs in various lengths which are arranged to be braced by a rod running the entire length of the tank and secured with lock nuts each side of the leg. The legs are drilled so as to fasten to the floor and are fastened to the tank by tap bolts, lugs being cast on the bottom for this purpose.

THROUGH the kindness of J. B. Sawyer of the Board of Health of Manchester, N. H., we have received a pamphlet with the regulations for the plumbing and drainage of buildings in that city. These regulations are of the modern character and went into effect May 1.

MCELROY & Co. have opened a plumbing and gas fitting establishment at 516 Santa Fé avenue, Pueblo, Col., where they are doing a nice business.

INSPECTOR OF PLUMBING R. S. BEMIS, Providence, R. I., has recently appointed Horace B. Holland as assistant inspector. Mr. Holland has been in the employ of Thomas Phillips & Co. for 20 years, and is highly recommended as a first-class man for the position.

BENJAMIN F. SHAW, Wilmington, Del., has the contract for the plumbing work on the new street railway of the Metropolitan Electrical Company in Reading, Pa.

GEORGE GRUSSING, architect, Chicago, has prepared plans for a residence to be erected at Watertown, N. Y., for Mills Kilby, to cost about $20,000, to be provided with the best of modern plumbing, hot water heating and electric light.

P. D. ARMOUR & Co., Chicago, will erect a large market and barn at 1136 West Madison street. It will be provided with plumbing fixtures and stable fittings.

HEATING AND PLUMBING.

NEW WORK AND CONTRACTS.

AMONG other plumbing contracts secured by G. M. Sinclair, Hoboken, N. J., may be mentioned one for $5000 for the Mayor of that city, and another amounting to $3000 for William Winges of the same place.

ISAAC COFFIN & Co. of Boston, Mass., are placing a No. 210 Richmond hot water heater in the dwelling owned by Rev. Amos Harris, Everett, Mass.

THE RESIDENCE of Francis Jewett, Lowell, Mass., will have a heating plant installed by the H. R. Barker Mfg. Company of Lowell, Mass., who will use a No. 33 Richmond Victor steam heater.

JOHN F. MULVEY has the contract for heating the private residence of Mrs. Susan H. Cook of Woonsocket, R. I., and will use a No. 44 Victor steam heater.

ARCHITECTS W. W. BOYINGTON & Co., Chicago, have prepared plans for a three story flat building to be erected on Flourney street.

ARCHITECT L. G. HALLBERG, Chicago, has plans for a store and apartment house to be erected on the corner of Clark street and Belmont avenue.

JOHN A. SCOLLAY, 74 Myrtle avenue, Brooklyn, N. Y., has taken the contracts for the heating apparatus for the swimming baths of the Twenty sixth Ward Branch of the Brooklyn Y. M. C. A.; the large apartment house of N. Lucken, Brooklyn; the large boarding and livery stables of E. E. Wheeler, Brooklyn; a range of greenhouses for H. Fischer, Great Neck, L. I; four greenhouses for Geo. Kruse, Jersey City; a range of violet houses for A. McKellar, Rockland Park, N. Y.; the private conservatory of the Hon. Theo. Koeler, Long Island City, and also three large steam boilers for the Ogden apartment houses, Brooklyn.

C. S. BARKER will build an apartment house to cost $50,000 at Superior, Wis., which will be heated by steam and have a plumbing system.

THE NEW BOARD OF SUPERVISORS of Warren County, Ill., have appropriated $35,000 for heating, lighting and furnishing the new court house.

CROOK, HORNER & Co. of Baltimore have been awarded the contract for supplying the heating and ventilating apparatus for the United States Post Office building at Staunton, Va., on the firm's bid of $2591.

JAMES H. MACK, Fitchburg, Mass., has been awarded the contract for plumbing the new High School building at that place. The plans call for 81 water closets, 30 lavatories, 8 drinking fountains, 30 urinals, and hydrants on each floor for fire purposes; all piping exposed to be brass, nickel plated.

SEALED PROPOSALS will be received at the office of the custodian of the United States Marine Hospital, New Orleans, La., until May 28, for furnishing a new water supply to the hospital.

THOMAS & RAPP have been engaged to prepare plans for the reconstruction of a school building, recently destroyed by fire, at South Evanston, Ill., for the Board of Education. It will be three stories high, with exterior of buff pressed brick and Bedford stone, and will be heated by steam.

S. S. BEMAN is letting contracts for two school buildings, at Pullman, Ill., for the Pullman Palace Car Company. They will be of various dimensions—one three stories high, built of pressed brick and stone, have slate roofs, hard wood finish, steam heat, gas fixtures and the latest improvements, at a total cost of $80,000.

M. J. DALY, Waterbury, Conn., has been awarded the contract for heating and plumbing the Apothecaries' Hall Company's block. Each room is to be heated and fitted for gas and electric lights, hot and cold water.

BIDS will be received by the authorities of the Western Female High School building, at Baltimore, Md., up to May 16, for two methods of heating and plumbing. Separate bids will be received for a steam plant and a hot air plant, and for a dry closet system and a plumbing system, using water closets, &c.

THE JOHN DAVIS COMPANY, 69 to 79 Michigan street, Chicago, are to install a hot water heating plant in the flat building of Giles Hubbard Indiana avenue and Forty-fourth street.

A. C. HICKEY, 69 South Clinton street, Chicago, has the contract for plumbing, sewerage and gas fitting in the double flat building of Henry Horne & Co., 169 and 171 South Morgan street.

AMONG the contracts recently taken for plumbing, gas fitting and sewerage by E. Baggot, 169 and 171 Adams street, Chicago, can be mentioned the following: Residence of C. J. Blair, Drexel Boulevard and Fiftieth street; factory of Phelps, Dodge & Palmer Company, Twenty-sixth street and Shields avenue; residence of D. B. Jones, Lake Forest, Ill.

CHARLES A. KLIE of Columbus, Ohio, has the contract for the plumbing work and drainage to be done in the new court house to be erected at Toledo, Ohio.

BROOMELL, SCHMIDT & Co., Limited, York, Pa., are using in one of their heating contracts one of the No. 6 hot water boilers made by Thomas Weathered's Sons of New York City.

GEORGE H. MURPHY, Bound Brook, N. J., has just completed the plumbing work in the residence of Mrs. Giles.

GEORGE G. HARGRAVES, Kansas City, Mo., will use a No. 6 hot water boiler made by Thomas Weathered's Sons, New York, for heating a residence in that city.

THE AMERICAN HEATING & CONSTRUCTION COMPANY, 69 Centre street, New York, will install a steam heating plant, using an Economy boiler, in the apartment house of Peter Fuchs, Ninety-fourth street and Madison avenue. They are also running the pipe for the refrigerating plant in the cold storage building of Wills Brothers, 143 Chambers street.

THE BOILERS of the H. B. Smith Company, 133–137 Centre street, New York, will be used for heating the Young Men's Christian Association building at Plainfield, N. J., and the residences of W. T. Campbell, Newark, N. J., and Charles L. Johnson, Ansonia, Conn.

THE SECRETARY of the Treasury has awarded the contract for supplying steam heating and ventilating apparatus for the public building at Danville, Ill., to J. T. Foley & Co. of Evansville, Ind. The contract price is $4790.

SEALED PROPOSALS will be received at the office of the Comptroller, in the Stewart Building, up to May 17 for alterations to the steam heating and ventilation and for the plumbing and gas fitting work in the new Criminal Court House at New York City.

ADDITIONS will be made to School No. 6, Terre Haute, Ind., that will require a heating and ventilation and a plumbing system. The entire work must be completed by August 30.

PROPOSALS will be received up to May 16 for the heating, ventilation, plumbing and gas fitting for a school building in district No. 50, Buffalo, N. Y.

A. F. SPETTEL, La Crosse, Wis., has let the contract for the plumbing work at his studio building to G. J. Egge.

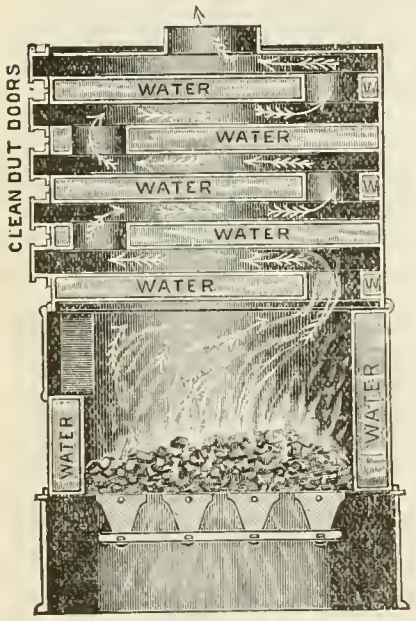
THE entire stock of roofing sheets held by one sheet mill was bought at market prices by a Canton concern, and there is a good demand for all that can be turned out by those mills in operation. The stoppage has become a source of annoyance both to buyers and mill operators, and no relief is expected for at least two weeks to come.

The railway companies have made very large reductions in the staffs of their mechanical departments. This has led to a great decline in the railway demand for heavy metals.

STEAM AND HOT WATER.

The New Lily Hot Water Heater.

Rubel & Co., 75–77 Lake street, Chicago, manufacturers of the Lily line of steel ranges, furnaces, steam and hot water heaters, are introducing the new Lily hot water heater, which is herewith illustrated. The heater is constructed of cast iron, on the circular, sectional principle, by which any section may be readily removed or replaced, and admitting of it being "knocked down" and taken through narrow passages. It is portable, requiring no brick work in setting, and consists of the base, containing the grate frame and grate and forming the ash pit, the fire pot, and from three to five sections placed alternately, and lastly surmounted by the top casting. The grate is self dump-



The New Lily Hot Water Heater.

ing and shaking, anti-clinker, cleanly, the ashes falling into a closed pit. The fire pot is cylindrical in form and of sufficient size to hold a quantity of fuel not necessitating continuous firing or attention. The door for feeding fuel is large, and at such a hight as to admit of fuel being supplied and distributed to any portion of the grate desired. The circulation of the heat is as follows: The hot gases from the fire pot come in contact with its surfaces, impinge against the bottom of the first section, circulate to the rear, and pass through the smoke flue into the expansion chamber, where, expanding, they come in contact with the top surface of the first section and the bottom surface of the second section; then passing forward to and through the flue hole in the second section, which is on the opposite side of the boiler from the first flue hole, as shown in the cut, to the second expansion chamber, and so on successively until they have passed through five expansion chambers and acted upon ten horizontal surfaces.

The return water of circulation is received into and enters the fire pot through two openings at its side and rear, and is circulated around the fire pot to its exit, at the opposite side; there it is conveyed to and through the first section, passing into the several sections directly opposite from where it enters the previous one, and so on alternately from one section to another, until it reaches the top section, where it leaves the heater. To prevent the water in its passage through the rings from going direct from the inlet to the outlet and the water around the sides remaining dead or inactive, circulating plates are introduced by which the water follows a serpentine course through each section. Provision is made for thoroughly cleaning the heater by means of large clean out doors in the front, by which any deposit may be readily and rapidly removed from both bottom and top surface of each section.

HEATING NOTES.

The United States Radiator Company, Dunkirk, N. Y., are a new organization which will carry on the radiator business built up under the name of the Harrell Steam Heating Company. The change is in the name only, the management remaining the same. Some disadvantage has been experienced from the wrong impression given by the old name. The business has grown in the five years of its existence till it taxes the capacity of the large new buildings in which the manufacturing is done. An increasing trade is expected when the new things that are in preparation are put on the market.

J. Henry Smith has retired from the firm of Getchell & Co., Bangor, Maine. Geo. W. Getchell will continue the plumbing and heating business under the same name.

The certificate of incorporation of the Queen City Radiator Company of Buffalo, N. Y., has been filed. Their capital stock is $300,000. The directors are Walter F. Bryant, Orrin Bryant, William H. Harell, Nathaniel N. Hunt and Marcus M. Drake.

"Warmth for Winter Homes" is the attractive title of an attractive pamphlet published by the United States Heater Company of Detroit, Mich. This is a little volume of nearly 100 pages, bound in colored paper, containing within its covers a general treatise on heating, many illustrations of buildings warmed by the several boilers of the United States Heater Company, and at the end a number of testimonial letters, together with illustrations of the boilers.

Dion Geraldine is at the head of a company recently formed at Chicago to abolish the smoke nuisance. Their plan is to take charge of all steam plants in the business district now controlled by the owners. It is said that they will make a contract with a man who has a steam heating plant in his building to run his engines, furnish light, heat and power cheaper than he can do it for himself, and will give a bond to carry out the contract. It is claimed that they can run a large number of small plants cheaper than the owners can operate them singly. By buying fuel in large quantities, putting on the latest devices for consuming smoke and saving coal and operating all the plants with a corps of trained engineers and firemen, they claim that they can effect a neat saving under the cost of running detached plants. Bond is given that the service will be satisfactory and guarantee is given their customers against suits under the smoke ordinance. They are confident that the plan will succeed and that when it is put in operation there will be no more complaint of the smoke nuisance in the business district.

In a trade edition of the Quebec Morning *Chronicle* is an interesting account of the Mechanics' Supply Company, dealers in gas, water, steam and plumbing supplies, &c. Among other firms for whom they are agents are the Toronto Radiator Mfg. Company, Warden, King & Son, Jenkins Brothers, Edward F. Keating, and the Toronto Steel Clad Bath Company.

Edwin C. Mason, Madison, Wis., will make a specialty of the heating business in future, having sold out his interests in all other lines.

The Alexander Iron Works have been recently organized at Alexander, Ind., and in addition to running a general foundry and machine shop, they will make a specialty of wrought iron pipe and pipe fittings, both cast and malleable, and will cut pipe to specification. They will also carry a full line of Lunkenheimer valves.

We are indebted to the Richmond Stove Company, Norwich, Conn., for another batch of illustrated and descriptive catalogues of the Richmond steam and hot water heaters, which they issue in the interest of their agents throughout the country. The firms are J. B. Jackson & Son, Nashua, N. H.; Higgins & Co., 379 Lexington avenue, New York; C. M. Briggs, Athol, Mass.; H. K. Austin, Reading, Mass.; E. G. Kelly, Peabody, R. I.; Barker Brothers, Newport, R. I.

The first catalogue of the Fowler Radiator & Mfg. Company of 435 North Broad street, Philadelphia, Pa., is being issued to the trade. It consists of 12 pages in a dark green cover with gilt lettering, and is devoted to the Fowler radiators, showing cuts of the radiator complete and with ornamental base and cold air dampers. The radiator is also shown set up with a register taking air from outdoors. The last two pages are devoted to giving all the necessary dimensions for both their semi-direct and direct flue radiator for steam or hot water.

President Bond of the American Radiator Company of Chicago was a visitor at the New York office this week.

The J. H. McLain Company, Canton, Ohio, have established a New York office at 69 Centre street, in the charge of D. R. McCallum, well known to the

trade throughout the United States. They are now decorating their show room previous to the arrival of their samples, when they expect to make a display of their different goods, with the Humber hot water apparatus and the Cambridge steam boiler as leaders of the line.

Among the contracts recently taken for steam heating by Rubel & Co., 75 and 77 Lake street, Chicago, can be mentioned the following: 12-flat building, of B. Eisengrath, Center avenue, near Van Buren street; 12-flat building of Mandel Bros., Vernon avenue, near Thirty-fifth street; 12-flat building of Harrison McGinsie, Boule vard place; flat building of H. Burckland, Forty-second place.

H. R. Wilson, architect, Chicago, has planned for Mr. McAdam a two-story residence. to be built on Vincennes avenue, near Forty-ninth street, to be heated by steam.

The American Radiator Company, 94 Centre street, New York, report a carload of radiators sold for shipment to England.

F. B. Townsend, architect, Chicago, has prepared plans for a two-story and attic frame residence, to be erected by J. W. Slayton, at Argyle Park, Ill. It will be finished in hardwood and heated by hot water.

Architects Raeder, Coffin & Crocker, Chicago, have prepared plans for a seven-story wholesale building to be erected at the corner of Franklin and Van Buren streets for A. E. Kent & Son. The interior is to be of mill construction and heated by steam.

A batch of circulars received from D'Este & Seeley Company, 29-33 Haverhill street, Boston, Mass., illustrate and describe a variety of the Curtis steam goods. One relates to the Curtis balanced steam trap, another to the Curtis boiler feed regulator, a third to the Curtis temperature regulator, while a little pamphlet gives descriptions and price-lists of a large number of Curtis specialties, including pressure regulators, return steam traps, &c.

Bement & Co., 226 La Salle street, Chicago, issue a small circular descriptive of the feed pump governor and automatic feed water regulators which they manufacture. A cut is shown of the governor and full description is given of its operation and essential features.

The Sam'l I. Pope Company, heating engineers, have moved their office from 360 Dearborn street, Chicago, to suit 207 Medinah Temple Building, Jackson street and Fifth avenue.

The American Heating & Construction Company are a new business house at 69 Centre street, New York. They will make a specialty of piping for power or heating and for refrigerating work. The company are composed of D. A. Bridge, well known to the trade from his long connection with the John Simmons Company, who will look after the office of the company, and C. D. Smith, formerly with the A. A. Griffing Iron Company, who will look after all outside work.

Alfred Smith, architect, Chicago, has designed a residence for J. W. Janney, to be built at 4729 Greenwood avenue, at a cost of $22,000, to be heated by hot water.

The Metal Worker was favored the past week with a call from C. S. Graves, one of the representatives of the American Boiler Company, 94 Centre street, New York, who reports a gratifying demand for the steam and hot water goods which he has to offer.

Dinwiddle & Newberry, architects, Chicago, have prepared plans for an apartment house to be built by L. G. Wells on Marshfield avenue, near Taylor street, at a cost of $35,000. It will be constructed of Georgia marble, with a red tile roof, and be heated by hot water.

F. Richter & Son, 382 Sixth street, Milwaukee, Wis., have closed a contract for heating a new $10,000 school house at Lancaster, Wis, with their fan system.

W. L. Klewer, architect, Chicago, has prepared plans for a four-story store and flat building to be erected by E. M. Raworth on North Clark street, north of Diversey, at a cost of $36,000. The interior will be divided into 16 apartments of six rooms each and four stores, to be heated by steam.

Gummey, Spering & Company, Philadelphia.

Gummey, Spering & Co. of Philadelphia, importers and manufacturers of tin plates, &c., are moving their offices and the stock formerly carried at 1023 Market street in Philadelphia to more commodious quarters. They will in future occupy the large warehouse in the newly built brick building situate 149-151 North Tenth street in that city, where there are excellent facilities for carrying a large and heavy stock of their well-known goods. The main floor space in their new quarters covers an area 55 x 176 feet, and there is a basement of the same dimensions. Convenient offices have been located on the main floor, and two very large safes installed in them. Behind the offices is an electric elevator built by Morse, Williams & Co. of Philadelphia, having a lifting capacity of 4000 pounds. They propose to carry an immense stock of tin plates, and have already on the floor, grouped according to branda, upward of 2,000,000 pounds of plates. One group of Climax roofing plates alone represents a weight of 250 tons. Other noticeable brands of roofing plates on the floor are Pennsyl Old Method, carrying 45 pounds of coating to the box of 112 sheets; Leominster, extra coated; Waldo, Alderly, Phœnix, Liberty, Eagle, Venus and Flag. Bright plates cover Phœnix, Climax and Mars brands. All these plates are made in the firm's own works at Twenty-sixth street and Washington avenue, Philadelphia. Besides their own productions they carry a large stock of imported brands of plates. They also handle large quantities of black and galvanized sheet iron, plate iron, and a general line of roofers' and metal workers' supplies, metals of all kinds, a complete line of furnace registers in iron, solid brass and bronze, and other goods of a miscellaneous character. With their other warehouse at Swanson and Catherine streets, the new quarters will enable the firm to keep up with the requirements of their increasing business, and allow of the carrying of a much larger stock than heretofore.

Morfa Tin Plate Works, one of the largest in Wales, were closed down this week owing to the depressed condition of the market.

FLASHINGS.

Detroit Conductor Pipe Company, Detroit, Mich., issue a card to the trade announcing that they have designed and built special machinery for the manufacture of corrugated conductor pipe in 10-foot lengths, for which product they claim particular advantages. The ends are said to fit together easily and the pipes are made from any gauge up to No. 24. The firm are now building machines for the manufacture of a line of eave troughs and hangers and will carry an assortment of tinners' supplies.

According to a report on the values of building stone, &c., produced in the United States during 1893, compiled by Dr. W. C. Day of the United States Geological Survey, the slate produced during the year was valued at $2,523,-173, of which $1,472,275 is credited to Pennsylvania. The product of Vermont was valued at $653 572, and of New York, $204,982. The valuation of the product of other States is given as follows: Georgia, $11,250; Maine, $139,-200; Maryland, $37,884; New Jersey, $3653; Utah, $850, and Virginia, $117,347.

Charles E. Eckstein & Co., who make a specialty of wrought iron ornaments, moldings, special shapes in rolled and forged iron, &c., have removed to 45 Vesey street, New York.

The Knisely & Yeldham Roofing Company, 68 to 74 West Monroe street, Chicago, have changed the name of their company to Knisely & Yeldham Company.

In a recent issue of the *Mercantile and Financial Times* is an appreciative notice of the firm of John Galt & Sons, who have just moved into their new offices in the Postal Telegraph Building, at the corner of Murray street and Broadway, New York. The firm are wholesale and retail dealers in all the various kinds of roofing slate in demand at the present time, including Bangor, Lehigh, Chapman, Pennsylvania, Black Vermont, Red, Purple, Sea Green and Unfading Green and also the Monson and Brownville, Maine, slates.

Schaefer & Heimink is the name of a new firm in the tin, slate and metal roofing business at 1363 Third avenue, near Seventy-eighth street, New York.

Bredfield & Resig have opened a tin, copper and sheet iron working shop at 516 Santa Fé avenue, Pueblo, Col.

The American Roofing Company, St. Louis and Cincinnati, report an excellent demand for roofing, siding, &c. They are making several large shipments to Colorado and the Coast, taking advantage of the cut in freight rates. They consider the outlook very encouraging for a continuance of the present demand.

A. W. Cooper & Co., 671 West Lake street, Chicago, are to furnish the red slate roofs, copper cornice, bays, gutters, flashings, &c., for the residence and barn of R. M. Wells, Michigan avenue and Thirty-eighth street; galvanized iron work, slating, tinning and skylights for the apartment building to be erected on the south side of Boulevard place, east of Grand Boulevard, for H. M. Alfonso; galvanized iron cornices, tin shingled tower, &c., for the office building of Phiffer & Fishback, Lamont, Ill.

STOVE TRADE NOTES.

Address of President Dana.

In opening the first session of the twenty-third annual convention of the National Association of Stove Manufacturers, held in Chicago the first week in May, President George D. Dana delivered the following address:

Long established custom has made it necessary that I should address you at this time. It would afford me much pleasure to have the rule changed, but as it has to be, I shall be brief that you may devote the more time to the consideration and discussion of the most excellent papers that have been prepared for you. One of the pleasantest and most instructive features of our conventions has been the interchange of thoughts and experiences that were made in the lobbies of the hotels in which our conventions have been held. This has been both pleasant and instructive, but it has made it difficult to open our meetings promptly at the hours set. Recognizing the value of these informal gatherings in the lobbies, your officers have thought it best to cater to this desire for informal discussion, and that all may have the same opportunity, we shall at the time of the noon adjournment have luncheon served in this room, and we hope that all will remain here and by their presence help us to expedite business.

History of the Stove Trade.

In February, 1872, the stove trade was thought to be in such an alarming condition that a call was made for a meeting of manufacturers, to be held in New York City on March 6, 1872, to consider the situation. At that meeting John S. Perry presided, and, while admitting the poor condition of the trade, he gave facts and figures to show what could reasonably be expected in the future, and said: "In view of these stupendous figures, is there any occasion for undue anxiety, lest any should fail to command a fair share of business?" Time has proved the correctness of his estimates, and verified his predictions. It is remarkable how the history of the stove trade has repeated itself; the conditions existing today are analogous to those of 10 and 20 years ago. I will call your attention to the utterances of your presidents at the meetings in the years following the panics of 1873 and 1884, and let you judge the future by the past.

At the annual meeting in February, 1874, in his address the president says of the business of the previous year: "Our sales were generally satisfactory in amount and the prices well maintained up to the time of the terrible revulsion."

"The prices of the more common qualities of stoves became somewhat unsettled toward the close of the year. But it has been generally remarked that they were better maintained than might have been expected under the trying circumstances, and this was in a great measure due to the influence of the association."

"I venture to say that in no department either of mechanical or commercial industry has there been less suffering than the one which we represent, and we may confidently predict that in the work of recuperation it will be in the front rank."

Again, at the June meeting of 1874 he says: "It is a cause for regret that the general business of the country and of the world is not in a more satisfactory condition. This depression is not confined to our own country, but appears to be equally severe in Great Britain, France, Belgium and other iron producing countries."

"In our present troubles we call loudly upon the Government for aid; the Government is powerless to render any permanent assistance—demand and supply are the only regulators, and they are controlled by a power which is supreme." "After the crisis of 1837, it was not until 1844 or 1845 that any substantial improvement was apparent; after the disaster of 1857 business remained for the most part unsatisfactory until 1863 or 1864." And after reciting all this he shows his hopefulness by asking, "Does any one believe that ten years or six years, or even two, will be required after the panic of 1873 to develop a reasonable prosperity?"

In 1876 President Jewett says: "The stove trade for the past year has necessarily sympathized with the general depression growing out of the financial situation. The trade has, however, been steadily working off its surplus stock." I do not speak of this as a necessarily discouraging fact, but it is one which manufacturers must recognize. The class of men who cherish the theory that there is to be a grand reaction in trade and a recovery in prices are doomed to disappointment. The period of inflation and unhealthy speculation is past, and values are to be adjusted to a different standard. We must accommodate ourselves to the shrinkage which has already taken place, and be content with moderate margins of profit. There is no magic wand in the hands of the President or Congress that can transform the financial situation. The Government, like the stove manufacturer, must practice economy, insist on retrenchment, and labor faithfully to reduce the balance on the wrong side of the ledger. In June of the same year there was no change in the situation, and stove men were looking hopefully forward to a gradual, if not speedy, return of better times. In January, 1878, the stove trade of 1877 was pronounced as more satisfactory than for many previous years, and with reduced stocks on hand and large crops harvested, the stove men took heart, but did not dream of advancing prices; they were conservative, and in 1878 began to reap the reward of economy and patience. The words of President Sard, in June, 1884, are directly applicable at this time. He says: "The general characteristics of the spring trade have been dullness, a disinclination to buy except for the present needs, an absence of excessive anxiety to force the sale of goods, and a larger restriction of production. The smallness of profits at last year's prices served to check any tendency to lower rates, except in cases where goods were undesirable, obsolete or perhaps higher than the general market."

In February of 1885 he says: "The course of general trade during the past year has been unsatisfactory and uncertain; the hopes which were entertained in the early part of the year were not realized. Labor has been dissatisfied and unable to obtain full employment even at lower wages." In June, 1885, he says: "The depression and congestion continue to prevail."

The Business Situation Past and Present.

How very aptly these words will apply to the present condition of our business you can all see. I ask you to compare carefully the business situation then and now, and answer for yourself the question, Why should we now expect an earlier and fuller resumption of business than has been had after preceding financial troubles? After the panic of 1873, it was five years, or not until the fall of 1878, that there was any decided improvement in business. In the fall of 1879 began the boom that made the years of 1880 and 1881 so pleasant and profitable to stove makers. The condition continued up to the spring of 1884, when the failure of Grant & Ward brought on another financial depression, and called a halt in all business enterprises. In the stove trade, as well as in other lines, business was slow to improve and it was not until 1891 and 1892 that we had what could be considered generally good years. In 1893 up to within a few weeks of our last annual meeting the business had been unusually good, but the storm broke and carried away all hope of a prosperous fall trade. With the abundant harvest of last year, there seemed to be no reason why we should not have had a fairly good fall trade. In some localities it was better than in others, but generally it was not satisfactory. We then looked hopefully forward to a revival in spring. Our spring trade is now a thing of the past, and if I may judge from the reports made in answer to the request of our secretary it has been fully as much of a disappointment as was the business of last fall. Our business experience is not very different from the experience of those in other lines of trade, and like effects are the product of like causes. In my opinion the present depression, which is almost world wide, is the result of overspeculation, overtrading, overproduction. The terms are synonymous, and only vary as applied to different branches of business. We are now at a point where there is no fictitious demand; the supply is still greater than the demand, and trade will continue dull until our normal consumption is reached and dealers will once more be willing to carry on their floors more of the products that now fill our warehouses. I think it will be admitted by all that less than the usual number of stoves were in the hands of manufacturers at the close of last year's business; that less than the usual number have been made this spring, and yet the present supply is ample for all requirements. The example of those who have been forced to economize has been contagious, and those who did have means, doubtful of what the future might have in store for them, bought only what they needed. The dealer who was in the habit of carrying a dozen or more of samples on his floor and in stock cut them down one-half, and do you know that the reduction of only two stoves each in the stock usually carried by dealers means over 60,000 stoves, which is equal to the product of a very large foundry, and when this is multiplied by three, which I think can safely be done, it means that stove manufacturers have lost in the mere reductions of stocks usually carried by the dealers a business of nearly $2,000,000. This is a healthy condition for the dealer, but hard on manufacturers.

Encouraging Features.

We can get some encouragement for the future from the fact that so few stove manufacturers and so few sellers of stoves were forced to the wall during the past year. It is gratifying because it shows that the trade generally has been done on a safe and conservative basis. Another matter for congratulation is the steady maintenance of prices and terms in spite of temptation to cut; that there has been no general cutting of prices cannot be gainsaid, and it is due in great measure to this association, whose traditions have always been that it was folly to attempt to permanently gain trade by reducing prices below a paying basis, or offering terms that were unbusiness like and dangerous alike to seller and buyer. While this association has never taken any positive action on the question of terms or prices, its recommendations have always been on the right side, and the discussions have shown a strong undercurrent toward the restriction of terms and the maintenance of reasonably profitable prices, and that this has had good effect is now shown. What the condition of trade would now be had this association never existed can better be imagined than described. It is left for us to continue in the same conservative management of our business that has prevailed in the last year, and be thus able to take advantage of the better times that are sooner or later sure to come, and which we, by our action, can help to hasten.

THE D. S. PHELPS COMPANY, Detroit, Mich., have an exhibit at the Detroit Pure Food Exhibition, consisting of Jewel steel ranges and Merit cast iron ranges. In connection with this display the D. S. Phelps Company make an elaborate showing of house furnishing goods, which includes two sizes of the Van Wie gas range and a specimen of the Pasteur germ proof water filter.

The Education and Production of Efficient Workmen.*

BY HENRY CRIBBEN.

The limited time I have had to devote to this subject prevents my going thoroughly into its salient points, but I will try to outline, as best I can, how in my judgment we can secure good and efficient workmen.

Let us first define what in our judgment constitutes a good and efficient molder. He should be temperate, industrious and work six days in each week, sickness or other unavoidable accidents excepted. He should be competent to perform the work assigned to him in a neat and workmanlike manner, and fully qualified at all times to make the necessary changes required of him that the business may demand. His work at all times should be made to strain weight, unless furnished dull iron by his employer, and oftentimes at less than strain weight, so that when the work is mounted into the stove, range or furnace the joints will be as perfect as the joints of the well fitted iron patterns from which he made his castings. He should see that his patterns are kept clean and free from rust, to enable him at all times to make work of quality that when finished shall nearly equal the pattern itself.

He should every day acquire some additional knowledge of his business, which is not only a trade, but an art that is at times mysterious and difficult to comprehend. He should apply himself whenever the opportunity offers to learning some part or portion of foundry practice, such as the best methods of lining the cupola, melting iron and properly mixing same after being melted in the cupola before it is allowed to run into the hand ladles. He should make a study of foundry machinery, including the blower and proper pressure required; should ascertain the best qualities of molding sand for making the different kinds of castings; should be kind in disposition, always treating his associates and employer with respect; should be honest, truthful and reliable, thus securing the respect and esteem of all with whom he comes in contact, and should constantly try to qualify himself to fill the position of foreman or superintendent, as employers will generally make their selection from among their employees if they find among them those that are qualified to fill positions of trust. Such men, in my opinion, constitute the good and efficient workmen; but this class is not numerous, and it has been the common remark of stove manufacturers when annually assembled at their meetings, "How small the number of efficient molders who have a thorough knowledge of foundry practice with the other necessary qualifications to make foremen or superintendents." There is at this time a far less proportion of good and efficient workmen than there was 30 years ago. The only reason that can be assigned for this is that the average molder has concluded in his own mind that when he learns the trade of iron molding he is destined to be a hewer of wood and a drawer of water for the balance of his natural life, and he has no ambition to perfect himself in his business nor to improve his condition when the opportunity offers.

Classes of Workmen.

There are at the present time three classes of workmen:

1. The traveling journeyman or Ho Bo, who goes through the country from foundry to foundry, remaining a sufficient length of time to earn enough to purchase some needed supplies and pay his board, and money sufficient to keep him until he reaches his next stopping place. He is, as a rule, never satisfied with the prices paid for his work, although efficient workmen make good wages on the same work at the same price; dissatisfied with himself and his associates, he creates as far as he can among his fellows a spirit of dissatisfaction and unrest. The work he makes, as a rule, is of an unknown quantity and of a very inferior quality, and on the whole he is a very undesirable class of man to have in your employ. The presence of this class has a very demoralizing effect upon the better grade of men.

2. The class constituted of those who have never received proper instructions when learning the trade, or that made a very poor use of the education received. They know very little about the art or mysteries of iron molding and do not seem to want to learn, for in their own estimation they are properly qualified workmen and put up as many flasks as the good mechanic. But when their production is inspected and counted, there are nearly as many of their castings go back to the cupola to be remelted as go to the cleaning room, and what are accepted are of inferior quality. If you speak to them of their inefficiency and tell them how to improve their work or save more of it, they put on a look of injured innocence and tell you that they are qualified workmen who have worked at the business eight or nine years, and are too experienced at it to need instruction from any one. They are so thoroughly imbued with egotism and conceit as to make them useless to any manufacturer.

3. There is still another class composed of workmen who are always learning, always on the alert to improve, who listen attentively and respectfully to any advice or instruction imparted by the foreman or superintendent, or even to any suggestions of their associate workmen, who take pride in producing good light castings and who can be relied upon to produce at least 95 to 98 per cent. good castings of all the work they put up on their floors. You will find these men at work every day of the week and every month of the year that the foundry runs, unless prevented by sickness or accident. If they are sick and not in condition to come to the works, they always have the foreman informed of their condition, so that if necessary the work on their floors may be made by some of their associates. Their discounts in the cleaning room and mounting department are very small, and the mounter finds little or no trouble in putting their work together. Stoves, ranges and heaters made by them give satisfaction in every respect. Castings made from a proper mixture of iron and to proper strain weight seldom, if ever, break from fire when made by practical and competent workmen.

Qualifications of Competent Workmen.

One of the secrets of producing competent workmen is in the selection of intelligent young men with the necessary qualifications, who with proper instruction and opportunities will aid in educating themselves in the mechanical knowledge of the trade. The applicant to learn a trade should be required to answer satisfactorily certain questions touching his future intentions as a workmen, such as:

Are you desirous of becoming a good workman?

Are you willing to honestly devote four years of your time to learn and to master as far as possible the art of molding?

Will you implicitly obey the instructions of your foreman and instructor in all matters connected with your employment?

Will you at all times while in the foundry refrain from vulgar or profane language, and from the use of intoxicating liquors, and discourage their use among your associates, not only inside the works, but at all times?

An apprentice should be taken on trial for a month to ascertain if he has the qualifications necessary for a capable workman, and the foreman or instructor should periodically report to the employer his fitness and conduct. If he be careless and shows a disposition not to apply himself, and the foreman is of the opinion that he has taken a dislike to his occupation, and the interest he seemed to have at the beginning is on the wane, he should be discharged at once, as he has not the qualifications necessary for an efficient workman. If, on the contrary, he evinces an interest in his occupation and a desire to learn, the foreman should give him every opportunity possible, and by counsel, advice and instruction assist him to secure the knowledge and skill he is in search of as rapidly as he is capable of receiving and applying it. He should receive encouragement from the superintendent and employer, who should take interest in the young man's efforts to become a good workman, should, when they meet, recognize him and inquire as to his progress, should stimulate him by words of praise for good conduct and application to business, and should spur his ambition to still greater efforts to become a good and skillful mechanic.

Some apprentices in the workshop, like boys in a school room, learn much faster than others, and should be encouraged, for the faster they learn the more profitable they become to their employers and the more money they earn, and if their efforts are properly recognized they will at a very early period approach to an equality with journeymen while still in their apprenticeship. If we desire to secure good and efficient workmen, we must furnish those who learn the trade with competent and qualified instructors to teach them its mysteries that lie hidden, so to speak, from the uninstructed in the brain of the qualified mechanic.

Employment of an Instructor.

All foundries employing 12 or more apprentices should employ at least one thoroughly competent instructor, as it is impossible for a foreman with his manifold other duties to find sufficient time to give that number of young men the instruction and advice necessary to enable them to become good workmen. If from neglect on the part of employers the apprentices are allowed to do and go largely as they please, of necessity when their time has expired many of them will be found among the worthless class of journeymen mentioned above.

The utmost care should be taken in the selection of foreman and instructors who have apprentices to educate; they should be thorough mechanics, competent and willing to instruct the apprentice by imparting to him the knowledge they themselves are possessed of in a manner that will not be offensive. They must be men of good moral habits and reputation, and their every day life, both in the works and outside, should be such as to challenge criticism for moral rectitude and sobriety.

The instructor should also possess a knowledge of how to instruct so as to secure the best results. He should be a judge of human nature, and when any pupil is worthy, he should be advanced by placing him on a floor located between two good workmen who will take interest in him and give him instruction and advice. All such cases of promotion and merit should be used as an incentive to spur others on to greater efforts by calling their attention to the rapid advancement of their associate.

Training the Apprentice.

The appentice should be strictly trained in the proper care of his patterns and tools, seeing that they are kept neat, clean and free from rust; to have a place on the floor for everything used; to observe a proper discipline, and to treat each other with respect. When he shows too great anxiety to make money on work he is accustomed to, by neglecting to do it well, he should be corrected, and if he still persists call a halt on him, by discounting all inferior work.

The apprentice should be indentured for the term of four years. The employer should feel in honor bound to give him a thorough and practical knowledge of the business, if the young man applies himself and carries out the instructions given him. It is also the duty of the employer to see and know that the instructor is doing his full duty in teaching the apprentices.

The method of indenturing will vary, as some of the States have no laws governing apprentices, and some that have laws on the subject are very unsatisfactory. As far as my knowledge extends, I would recommend the adoption of a contract with the young man, agreeing to pay him so much per week in wages, payable weekly or upon the ordinary pay day of the establishment, and a promise of a certain sum of money per week as a bonus to be paid at the expiration of his term of apprenticeship, provided he continues in the service and performs his duties faithfully during the four years. In case he is discharged for cause, such as neglect in performing his work, drunkenness, quarreling or fighting, he forfeits all claims to such bonus. Or it may be arranged that the apprentice work by the piece after the first trial month, for during that time he has been taught the rudiments of his trade, such as shoveling and riddling sand, keeping tools and patterns in good order, tucking bars thoroughly, and ramming up flasks containing simple work in a proper manner. He can be given simple plain molding to begin upon, and advanced when he has shown that he is making progress. So that from the time he begins work he will earn equal, if not greater, wages by the piece than he would have received by the week, and he has it in his power to increase his pay from time to time by the acquirement of increased skill and dexterity.

In working by the piece he should be paid a certain percentage of the price paid the journeyman molder, and in addition thereto a bonus of a given percentage on the amount of money earned by him during the term of his apprenticeship, payable, as in the case of weekly wages, at the ex-

* Read at the convention of the National Association of Stove Manufacturers held in Chicago, May 2 and 3.

piration of his time of service, provided he has performed his duty and has fulfilled the terms of his contract.

Let the wage system be what it will, it is very essential that the employer should take an interest in the young man, and see to it that he is properly treated and given every opportunity to become a skillful workman. He should see to it personally that the instructor is doing his duty. The apprentice should have easy access to his employer, who should hear him patiently and insure him at all times just treatment. He should be encouraged to save his earnings, so that when he becomes a mechanic he will feel thankful for the interest taken in his welfare.

The Apprentice System.

The apprentice system as it has existed for the past 30 years has been a source of annoyance and trouble to a great many manufacturers and of discouragement to the apprentices, for which to a very great degree the manufacturer on the one hand and the Molders' Union on the other are responsible. Apprentices have not been properly instructed Employed for the term of four years, during the time of their apprenticeship, they often do not learn to make more than six or eight different pieces of castings, and when as journeymen they are called upon to make a class of work different from what they have formerly made they are lost, so to speak, and are unable to produce good work, so that they are compelled to search for jobs such as they have made and they become known as specialty workmen. Since the close of the war and up to 1888, some two years after the organization of the Stove Founders' National Defense Association, there had been continual strife or warfare between the Molders' Union and the majority of manufacturers, the union making unreasonable and unjust demands as to prices that should be paid for labor and the enforcement of rules that were destructive of discipline and good order in any establishment, and the manufacturers resisting such glaring injustice, so that there were continual strikes and all means, fair and unfair, were used by both parties to accomplish the defeat of the other side. The union thinking and scheming how to make a success of their strike, would persuade the indentured apprentice to quit the service of his employer by agreeing to take him into the union and making him a full fledged union man and putting into his hand a union card, although he had not been employed at the business more than ten months or a year, and certainly was not a qualified journeyman molder. Some members of the union may deny this statement, but they are either ignorant of the facts or tell a falsehood to try to cover up the dishonorable and unmanly action of their unions. As the writer personally knows, 11 of his apprentices were taken into the union during the strike in his shop in 1884, some of whom had worked at the business less than nine months. The production of what is known as the hobo, and the inefficient, know nothing workman, is therefore directly traceable in a measure to the selfishness and neglect of the employer in not giving the apprentice proper instructions, but more generally to the dishonorable practices of the Molders' Union in inducing apprentices to leave their employers and by forcing on the trade with a union card in their pocket men utterly worthless as molders. But we are now looking forward to a brighter future and the production of a superior class of workmen, for since the organization of the Defense Association of Stove Manufacturers the Iron Molders' Union has in the case of its members abandoned strikes as a remedy for the differences that arise, and lets reason, justice and common sense prevail in the settlement by arbitration of all disputes.

Earnings of Workmen.

Having given the subject of good and poor workmen some considerable thought, during the 43 years I have been engaged in the foundry business, 18 of which were spent as an iron molder, working by the day or by the piece as the occasion demanded, my opportunities for securing authentic information have been greater than those of many of my associate manufacturers or of the ordinary workman, and my experience proves that the apprentice who serves his time, and by carelessness on his own part or neglect on the part of his employer to properly instruct him fails to become a qualified workman, loses at least 40 per cent. of his earning capacity, as compared with that of the good workman. I have watched with interest the respective earnings of the two classes, and find the average wages earned by the poor hobo and his companion, Mr. Know-it-all, to be from $2 to $2.50 per day by the piece, and that of the good workman from $3.50 to $4 per day; therefore, both being physically able to perform the labor required, the good workman being employed 11 months in the year of 26 days each, would earn, at an average of $3.75 per day, $1072 50, whereas the poor workman, working the same number of days at an average of $2.25, earns only $643.50, or a difference of $429 per annum against the poor workman. This loss is not confined to one year alone, but continues with him as long as he remains in the business, and if the average number of years he works is 15, he is a total loser to the amount of $6435. This is food for thought to both the apprentice and manufacturer. If the incompetent workman for the reasons given is in 15 years a loser of $6435, how much does the manufacturer lose by his employment when he occupies the same floor space as the good workman, but produces a little more than half the amount of castings and those of an inferior quality, but using about the same number of pounds of melted iron daily to pour his molds? The capacity of the manufacturer is reduced to that extent, besides the loss of remelting the large percentage of bad castings made.

If we can teach the apprentices that they can earn $429 more a year by becoming good and efficient workmen, it will not only stimulate them to acquire a more thorough and systematic knowledge of their business, but at the same time will prove to the employer that there is a large profit to him in turning out good workmen, and it will be a long stride in the right direction. Neither is engaged in the business for the sake of the trade or occupation, but solely for the money it gives. I am convinced that when this subject is taken hold of by employers and properly presented to the young men who are learning trades, an influence will be brought to bear on them that will bring forth good results in the near future, but it must be borne in mind that to secure such results the apprentice should thoroughly learn to make all the work, and especially the most difficult in the foundry in which he is learning his trade.

Improvement of the Mechanics.

It is a fact known to all that professional men are making rapid advances, perfecting themselves by study and experience in their various professions, but the condition of the mechanic has been quite the reverse, except in isolated cases. This is not a healthy condition of affairs. There is no good reason why the mechanic should not improve and become as skillful in the different trades and as thorough master of his calling as it is possible for the professional to attain in his vocation. And we as manufacturers should all agree from this time forth, as far as possible, to try and improve the standard of our workmen, by giving encouragement to our apprentices, by furnishing them better facilities, and by assisting them to improve the opportunities as they arise.

If the work of the apprentice is changed as fast as he becomes proficient and continues to turn out perfect castings for weeks successively, it will enable him to improve and will encourage him to become more skillful, and if properly followed up until he can satisfactorily make the most difficult work in the foundry, he will help to reduce this great army of incompetents hereinbefore mentioned, and at the same time will greatly assist in securing a large increase of good and efficient workmen in the line of our manufactures.

The Fuller-Warren Company of Milwaukee, Wis., are furnishing dealers handling their goods with water proof signs intended for display purposes. These signs are oblong in shape and are accompanied by a number of tacks specially adapted for the purpose, having sharp points and large heads. They are easily pressed into the sign for driving and do not pull or drive through as would be the case with a smaller head. These signs are embellished with the inscription, "Go to —— ——— for Stewart Stoves," the blank space being left for the name of the dealer handling the goods. The inscription is in white letters upon a deep blue ground.

Profit Sharing.*

BY C. S. PRIZER.

Would not every progressive stove manufacturer welcome the inauguration of a policy in the management of his business that, without diminishing his profits, would assure to him the best and most faithful service from his employees of which they are capable? If at the same time this policy would promote friendly and sympathetic relations between his employees and himself, and would cause his employees to feel the same interest in the quality of the product and the prosperity of the business which he himself feels, would not every stove manufacturer adopt it? The advocates of that modification of the wages system known as "profit sharing" make the following claims for their scheme when applied to manufacturing interests:

That it will increase the quantity of the product.

That it will improve the quality of the product.

That it will promote economy and care in the use of materials and tools.

That it will prevent strikes and labor difficulties.

That it will effect an improvement in the character and conduct of the workmen.

That it will reduce the expenses and largely obviate the difficulties of superintendence and inspection.

That by reason of the increased product and of the economies resulting from the operation of the scheme, there will be created an extra profit beyond the profit that could otherwise be earned by the business.

Definition of Profit Sharing.

Profit sharing may be briefly defined as any system under which the employees of a business house receive, as a bonus, at stated intervals, a part of the profits of the business in addition to their stipulated wages.

The basis and methods of this distribution will be determined by the varying conditions of different industries. In fact, an investigation of the leading examples of profit sharing in this country and in Europe shows no two cases in which the plans of distribution are identical. The advocates of profit sharing assert that no employer should consider that his own profits will be diminished by the distribution of a bonus to his workmen. They insist that the system must stand or fall on the proposition that under profit sharing the workmen create an extra profit over and above the profit that could otherwise be realized. It is a part or the whole of these extra theoretical earnings created by the system that is to furnish the fund for maintaining it. Participation in profits by workmen was first advocated by Turgot, one of the ablest of the early French economists, in 1775. He claimed, as do modern advocates of the scheme, that it would furnish a powerful incentive to workmen for the rendering to their employers of faithful, thorough and conscientious service. The plan seems never to have been put into practice, however, until M. Leclaire, a Parisian house painter, applied it to his business with marked success in 1842. Since that time, up to the year 1892, according to Nicholas P. Gilman, profit sharing has been adopted by about 300 establishments in Europe and America. About 100 of these cases are credited to the United States, but the records show that a number of houses in this country have abandoned the scheme after trials varying from one to eight years. Among the establishments noted by Mr. Gilman as having the plan in successful operation in this country are:

The Century Company, publishers, New York.
Pillsbury Flour Mills, Minneapolis.
Rogers, Peet & Co., clothiers, New York.
Globe Tobacco Company, Detroit.
Haines, Jones & Cadbury, brass goods, Philadelphia.
Procter & Gamble, soap, Ivorydale, Ohio.
Yale & Towne Mfg. Company, locks, Stamford, Conn.
Rand, McNally & Co., publishers, Chicago, Ill.
J. W. Tufts, soda water apparatus, Boston, Mass
Rumford Chemical Works, Providence, R. I.
N. O. Nelson Mfg. Company, brass goods, St. Louis, Mo.

The only instance of profit sharing in the stove business, so far as I can learn, is that

* Read at the convention of the National Association of Stove Manufacturers, held in Chicago May 2 and 3.

introduced by the late M. Jean Baptiste Andre Godin in the management of his foundry at Guise, France, in 1877. M. Godin is said to have been the first manufacturer in France to substitute cast iron for sheet iron in the construction of stoves. His experience in profit sharing seems to have been eminently successful, though his plan for distributing the bonus is quite elaborate and complicated, as the following account of it will show :

Distributing the Bonus.

" The profits of the year's business, after allowance is made for operating expenses, are subject to these deductions : 1. A charge of 10 per cent. on the value of movable property, and another of 5 per cent. on the immovable property, for depreciation. 2. Five per cent. interest on capital. 3. A certain amount for the educational privileges provided by M. Godin for his employees in his famous Social Palace. 4. A sum equal to 2 per cent. of the wages and salaries of the year for the benefit of the pension fund. The net profits remaining are then divided as follows :

" The reserve fund receives 25 per cent., a second 25 per cent. goes to the management, and the remainder is allotted to capital as a super dividend, and to labor as a bonus on wages. The usual interest on the capital of the establishment, and the whole amount paid out during the year in wages and salaries are added together. The proportion each sum bears to the total amount determines the respective shares of labor and capital. Thus in 1880, interest amounted to 230,000 francs, and wages to 1,888,000 francs. The bonus to labor was, accordingly, a little over eight times the amount of the super dividend to capital. The workman does not receive any part of his bonus in cash. It is all capitalized and applied to the purchase of shares in the business. No workman is admitted to participation who is not already the owner of one share of stock. All workmen, however, are encouraged to purchase stock. The interest on the stock held by the workmen adds considerably to their average earnings. In 1883 the house employed over 1400 workmen, of whom 793 were owners of stock, and hence participants in the bonus dividend. It will thus be seen that there is at work in this business an evolution which will finally result in a co-operative establishment."

Payment of Bonus.

In nearly all of the recorded examples of profit sharing, the workmen are paid but a small portion, if any, of the bonus in cash. The bonus is usually invested in a pension fund, applied to the purchase of an interest in the business, used to effect an insurance policy or to purchase an annuity, which shall be available when the workman shall become superannuated by old age or illness. In nearly all cases the benefits have been made to accrue only to the more important and efficient workmen, and to these only after they have been in the employ of the house for some stipulated period.

For those employers who believe that profit sharing constitutes a solution of the ever present labor problem there is the encouraging consideration that, unlike many other proposals for the settlement of this question, the plan can be carried into effect without legislative action and without securing the assent of a majority of the voters of the country. Each employer can test profit sharing for himself, beginning, if he so desires, in a tentative and experimental way, and extending the scheme as its success may warrant.

Suggestions for Stove Makers.

Should any member of the National Association of Stove Manufacturers desire to inaugurate a system of profit sharing, I venture to offer a few suggestions as the result of my investigation of the subject.

Let the management at the close of any business year announce to as many of its employees as it deems advisable to admit to the scheme, that in order to secure their full and sincere co-operation for the success of the business, it is proposed to divide among them, in proportion to their respective earnings at the close of the ensuing year, all of the surplus profit which it shall appear is due to their increased faithfulness, vigilance and efficiency. While this announcement to the employees should intimate that a fair and equitable method would be adopted for determining this surplus profit, the details of the method actually adopted for determining it should not be divulged to them, as the entire matter should be completely at the discretion and under the control of the employer. A number of experiments in profit sharing have failed because of differences between employers and employees regarding the amount of the bonus and the method of distributing it. Apply the plan to those employees who have been with the house for two years or more, in the following departments : molding, mounting, pattern, electro-plating, polishing, machinery, engine, selling, office.

Allow each employee the option of receiving his bonus in cash or of applying it to the purchase of stock of the company. If necessary, arrange for the issuance of stock certificates of small denomination, in order to afford employees better opportunity for acquiring a capital interest in the business.

The difficult feature of any plan of profit sharing which contemplates the distribution of an indeterminate bonus, is to estimate the increase of profit which has resulted from the operation of the plan. Various methods of estimating this increased profit will suggest themselves to the convert to profit sharing. The average profits, in percentages, of a number of ordinary business years might be taken as a basis, and the profit of a year under the profit sharing system in excess of such a basis might, taking into consideration the conditions prevailing during that year, be assumed to be due to the operation of the new plan. A more definite plan of distribution of profits to employees might be adopted by any stove manufacturer who is not afraid to take the full plunge into the policy of profit sharing. Out of the profits of the business a definite percentage might be first paid to the stockholders of the company. As much of the net profits beyond that as it is deemed feasible to pay out in a cash dividend might be divided equally, or in any other proportion, between the stockholders and those employees who are admitted to participation. Of course, any plan of profit sharing contemplates, before it is inaugurated, the existence of a profit at the close of the year, and I have therefore to confess with regret, that there are a great many stove manufacturers in the United States who, for an obvious reason, are not now, and have not for many years been, in a position to begin a trial of this beneficent scheme.

Objections to Profit Sharing.

The current objections to profit sharing, so far as the literature of the subject reveals objections to it, may be summarized as follows :

If workmen are to participate in profits in good business years they should also hold themselves ready to make up losses in years of bad business, by paying back at the close of the bad year a proportion of the wages they have received.

Profit sharing on these terms would be manifestly impracticable. If workmen are once permitted to share in the profits of a concern, they will soon insist that they be permitted to audit its books and accounts.

Profit sharing would result in undesirable publicity regarding the profits of a company.

If profit sharing is so sure to result to the advantage of both employer and employee, why has it not been more generally adopted? After having been tried for many years, in isolated cases, the number of houses practicing it is so small as to constitute an almost infinitesimal point in the immense world of business.

Profit sharing is merely a dream of idealists and philanthropists, and therefore not adapted to this hard and practical world. Profit sharing would, if generally adopted, and if the result claimed for it were realized, put workmen at the mercy of the managers. A good business manager would so conduct affairs as to be able to pay a bonus to the employees; a poor business manager whose employees worked just as faithfully as those in the former case, would not be able to realize a bonus for them.

Objections Controverted.

It seems to me that these objections are trivial and superficial. If nothing stronger can be urged against profit sharing the advocates of that industrial policy have a stronger case than have its opponents. Workmen would receive the current wages, without deduction, even if they had not been promised participation in profits. If no profit is realized their extra exertions due to the hope of receiving a bonus, yield them no pecuniary reward.

Very few investing stockholders ask permission to audit the books of the house in which their capital is at stake, and it is therefore unlikely that workmen without any capital invested in the business would do so. That profit sharing has not been more widely adopted does not prove the policy to be without merit. A strong force is required to overcome the inertia of habit, tradition and custom. It is no argument against any proposed innovation to call it an impracticable dream. Every man who has ever proposed a " better way " in any department of human activity has at first been charged with impracticability. Neither is it any argument against profit sharing to say that an incompetent manager will not be able to distribute as large a bonus to his workmen as will a capable manager. Under the present system the prosperity of the workmen is also inseparably linked with that of the establishment for which he works.

There are, however, fundamental reasons why profit sharing cannot fulfill the sanguine predictions made for it by its partisans

Von Thunen believed profit sharing to be " the only refuge and salvation of the working classes." Sedley Taylor, the learned English economist, gives the policy his unqualified support and asserts that its general adoption would result in great and permanent benefit to the mass of laboring men. Francis A. Walker says : " That profit sharing, if generally introduced . . . would be a cure for most of the labor troubles from which we suffer, seems to me beyond dispute." N. P. Gilman says : " Profit sharing is the one most practicable and most generally applicable measure of improvement (in the settlement of labor difficulties)." F. H. Giddings, a rising American economist, asserts that " profit sharing effects a more equitable distribution than can be realized by the unmodified wage system."

The American Association for the Promotion of Profit Sharing includes in its roll of officers, the names of such well known and practical men as Carroll D. Wright, N. O. Nelson of St. Louis ; Alfred Dolge of New York ; Henry R. Towne of Stamford, and George A. Chace of Fall River. Yet, notwithstanding, the weight of authority given to this movement by the able and eminent men who are engaged in promoting it, I am convinced that we cannot hope to find in profit sharing even a partial cure for the economic maladjustment of which the labor question is a symptom. In the cases where profit sharing has been successfully applied, the scheme has usually been carried out and reported upon by men of exceptional executive and administrative talent, who had strong prepossessions in its favor before inaugurating it. Were profit sharing applied to every productive and distributive industry it could not raise actual wages or improve the condition of those who toil. For, assuming that it will do all that is claimed for it in increasing the product and promoting the industry of workingmen, it is merely equivalent to inventions and improvements which augment the efficiency of labor.

If improvements and inventions which add to the power of labor could cure the economic ills that afflict us, we should long ago have reached an industrial millennium. Inventions and improvements that facilitate production are so far from constituting a solution of the labor problem that so close an observer as John Stuart Mill could say, " Hitherto it is questionable if all the mechanical inventions yet made have lightened the day's toil of any human being."

An Example of Failure.

An example of the failure of profit sharing to permanently raise wages is furnished by the history of the co operative coopers' associations of Minneapolis. At first all of these associations made money by eliminating the middleman and by effecting various economies in the manufacture of flour barrels. In his account of this interesting group of co-operative establishments Dr. Albert Shaw naively intimates that the co-operation itself was a marked success, but owing to a constant and unfortunate downward tendency in the price of barrels the workmen in these shops, who were all profit sharers, had finally to be content with the most meager returns for their labor.

That profit sharing has been applied with some degree of success in a few isolated cases is no proof that it would raise actual wages or increase profits if it were generally adopted, even assuming it to be as great an improvement as its advocates would have us believe. An improvement in machinery or in business methods may be an advantage to a house so long as the improvement

is confined to that one house, but the advantage is lost when the use of the improvement becomes general. When reading and writing were rare accomplishments the ability to read and write conferred distinction and had a money value.

It is impossible to raise wages above the point to which they gravitate under given economic conditions by any system of bonuses or premiums. When the English Government, attempting to mitigate the distress of underpaid agricultural laborers, paid out of the public treasury grants in aid of wages it was found that the recipients of these grants merely offered to work for that much less.

The advocates of profit sharing exaggerate what they term the "defects of the unmodified wage system." The assumption that a mere employee has little or no incentive to faithfully serve his employer is, I am confident, contradicted by the experience of every manufacturer in this meeting. An employee can usually promote his own welfare by conscientiously performing his duty toward his employer. The majority of workmen, in the stove business at least, instinctively put forth their best efforts to advance the success of the business.

Traveling salesmen could hardly be imbued with additional ambition or energy by the most liberal application of the profit sharing plan, as almost every traveling salesman knows that his remuneration depends directly upon the amount and quality of his work. The salesbook is a strict and vigilant superintendent. Yet traveling salesmen do not, on the average, render any better service than the other employees of a manufacturing establishment.

Profit Sharing in the Stove Industry.

It is doubtful whether the application of profit sharing in the industry of stove manufacturing would appreciably increase the product or improve its quality. The molders and the mounters, who comprise a majority of the force actually engaged in the work of making the goods in this industry, are turning out as large a quantity of product as can be expected of them. It is certain that the molders, at least, could not on the average turn out more work than at present without to some extent sacrificing health and longevity. That the piece workers in this industry do not, and need not, sacrifice quality by turning out a large quantity of product is proved by the fact that the goods of a well-known house, which probably turns out more stove plate per molder than any other in the country, are surpassed in excellence of workmanship and finish.

That a pecuniary interest in the success of a business does not have the magic and marvelous effect upon employees with which it is credited by the advocates of profit sharing is shown by an example that has come under my own observation. In this case a number of employees hold small amounts of stock in the company. Neither in the quantity of the work produced nor in its quality do these stockholding employees show any noticeable evidence of superiority to the average workman who has no capital invested in the company. I do not wish to be understood, however, as opposing the policy of encouraging employees to invest their savings in the stock of the company for which they are working. On the contrary, I believe that policy to be a good one, so long as the house is able to declare dividends, as it has a tendency to promote reliability and reasonableness among the men.

While it seems certain to me that we cannot hope to find in profit sharing even a palliative for the evils that in these times so sorely perplex the sociologist and the economist, yet the spirit that prompts such men as Wright and Walker and Gilman to turn to this policy is noble and commendable.

The fact that demagogues and social quacks find their occupation and opportunity in the existence of the anomalous industrial conditions that prevail over the whole civilized world should not deter thoughtful and conservative men from frankly facing the problems involved in our system of producing and distributing commodities, nor from earnestly seeking a solution of these problems.

Why have the numberless inventions and improvements that so immensely facilitate the production of wealth failed to assure a good living to every man who is willing to work?

Why is it that with boundless natural resources, which as yet we have hardly begun to use, vast numbers of men should be denied the opportunity of exchanging their labor for the things that labor produces?

What is the cause of that strange industrial congestion that prevents us from half utilizing the productive facilities at our command?

Why do wages, considered as a proportion of total production, constantly tend downward as the productive power of labor increases?

Why do the majority of business men find it increasingly difficult to secure an adequate return for their capital and labor?

These are the questions we must solve, or all of the splendid achievements of our civilization will finally avail us nothing.

Advantages and Disadvantages of Interchange of Information and Experience Between Stove Manufacturers.*

BY FULLER & WARREN COMPANY.

That a free and full discussion of methods employed and a frank interchange of data concerning every branch of the stove business would be of advantage to all members of this association seems entirely reasonable. Indeed, it can hardly be questioned, except on the supposition that the exchange of ideas would not be frankly done by some, or else that the burden of imparting information would come heaviest on a few whose knowledge is greater than that of the many. As to the first objection, while it is probably true that some would be only too willing to profit by any valuable ideas received while either refusing to impart anything valuable themselves, or doing it in such a manner that it would be of little value, it may be assumed that most people are not of that disposition, and, therefore, any objection to interchanging data because of them would be many times offset by the advantages to accrue to the great majority, who, it is fair to presume, would be candid in giving, as well as receiving, information. The other supposition, that a few might give to the many without a fair return, is also not a good objection. For, while it is true that in all bodies of men there are some who, because of superior knowledge have more to give than they can receive from any other individual, it is more than probable that they could gather as much information from all the others as they themselves would be able to give.

Free and Full Discussion.

By a full and free discussion of methods and a frank interchange of data is not meant merely the discussions that occur at these annual meetings, but a willingness between individual members to exchange or give at any time, when requested to do so, any data asked for regarding methods used in manufacturing and selling goods and collecting accounts. A knowledge of what your contemporaries are doing in manufacturing cannot fail to be of advantage; and this is so not because you may wish to use it against them, but because it sharpens your desire to be up to the times, makes you strive for new and better ways of working, and, in fact, gives you an interest and pride in your business that never comes to the man that goes along doing things in his own way, without the incentive that comes from contact with other men and methods.

And it is not only as a means of education that an interchange of ideas would be valuable, but it would really be a protection against unjust demands that cannot be refused, unless you can learn positively what your fellow manufacturers are doing. In your manufacturing departments it would protect you against payment of excessive prices for labor, for men cannot reasonably continue to ask one manufacturer to pay more than another for the same kind of work. This may seem to those who are not at present paying as great prices for labor as some others an unnecessary reason in their case for reciprocity, but they may rest assured it applies as closely to them as to their less fortunate fellows; for the associations of their workingmen, you may be sure, do not withhold from each other any data that will enable them to secure advantages, and the time will surely come when it will be necessary for the low paying manufacturers to meet a demand for advances to equal the prices paid by others, and then, to save themselves from paying more than the others, it will be quite necessary for them to know what the others are doing.

Some of the Advantages Resulting.

In your selling operations it would protect against unwarranted attacks on prices and terms by the retailer. As it is now the retailer has the manufacturer entirely at his mercy. He can, if he is unscrupulous, tell the salesman anything he pleases about terms offered by other manufacturers, and the salesman, in many instances, is obliged to be guided by the retailer's statements. Would this be so if the members of this association were willing to exchange information with each other? Would the continual increase in length of terms go on?

It is not the intention to make this a long paper, and as you are all probably familiar with such subjects, no more space will be given to illustrating it. The fact seems so clear that an honest interchange of data among the individual members of this association would be of advantage to all that it is earnestly hoped the discussions that may follow will be potent to accomplish something in the direction of an "interchange of information and experience between stove manufacturers."

* Read at the convention of the National Association of Stove Manufacturers, held in Chicago May 2 and 3.

The J. L. Mott Iron Works

of New York and Chicago have issued an attractive catalogue of furnaces, ranges and fire place heaters. It is known as Catalogue No. 1, to distinguish it from other publications of the company, No. 2 dealing with cook stoves, portable ranges and heating stoves, No. 3 with laundry ranges and iron heaters and No. 4 with furnaces and caldrons, steam kettles, &c. The printing is on an excellent quality of paper and the engravings are of such a character as to show to advantage the goods illustrated. Attention is first invited to Mott's Lenox double oven portable French range, made in several sizes and adapted for family, hotel and restaurant use. It is fitted with the makers' double action anti-clinker grate, roller ash sifter, patent warming shelf and broilers. Next in order is Mott's Defiance, made in several sizes and fitted with double ovens. It is made both portable form and adapted for brick work. Mott's St. George elevated double oven range is made in three sizes, while the single oven range under the same name is offered in one size. Mott's Defiance single oven range occupies a number of pages, after which Mott's gas shelf, provided with two burners and adapted for application to the Lenox or Defiance portable ranges, is illustrated. The closing portion of the volume is taken up with illustrations and descriptive particulars of Mott's Social fire place heater, which has been on the market for some time; the Osborne mantel stove, made under the Morrison-Sandford patent, and in construction being a return flue base burning stove with a draw center anti-clinker grate, dust flue and large illuminating section; Mott's Star furnace, made in portable form and for brick work, and the Comet, shown with and without exterior casing. Prices of galvanized iron range boilers are given, together with those of water backs, boiler stands, repairs, brick, grate bars, doors, frames, sliding dampers, &c. An interesting feature of the pamphlet is found in the illustrations of a cast iron flue lining made under Freyer's patent, one page being devoted to an illustration showing how the lining should be built in the wall.

THE UNION STOVE LINING COMPANY of Weir Village, Mass., resumed operations last week.

A Theory of Ornamental Design Applied to the Decoration of Stoves.*

BY JOS. LEON GOBEILLE.

To most of you the title of this paper will express exactly what we will discuss in the few moments allotted to us. You will see that it is really two subjects—"A Theory of Ornamental Design" and "Practical Application of Same to Stove Decoration." Between the two a gap occurs, which for various reasons, some of them obvious enough, we will leave open for another occasion.

The theory is simply an enlargement of the Newtonian suggestion that color and sound are, if not synonymous terms, at least so closely related as to be subject to like laws and like limitations. What we wish to show at this time is that form is included with sound and color, especially as understood when we speak of ornamental details. And when we speak of form we will take Webster's first definition—"The shape or external appearance of a body or figure as defined by lines and angles."

No one here will question that the effect of forms upon the eye is discordant or harmonious, according as their outlines and embodiment are agreeable, or the contrary, to that sensibility which we call good taste. The truth of the proposition will be apparent without argument.

It may also be set down that the perfection of art in form is that rich simplicity which attracts or repels the rudest minds. Out of many examples of the effect of simple lines to influence the mind of man two have been selected, which will be instantaneous in their action upon each one of you. Remember, they are an arrangement of elements, so primitive as to come below any written or picture language.

Symbolism.

It would be remarkable if every one here should agree with me as to what arrangement of lines into form is to-day the most potent symbol in the United States, attractive or repellant, as the case may be, yet that is precisely what you will do. It is shown in diagram marked Exhibit A.

It does not seem an easy task to select another composition as the second most effective and well understood design known. It is not an Acorn, nor a Diamond, nor even a Garland, and yet, as in the design of the cross, each one of you will agree that we have selected the arrangement of straight and curved lines, which deserves to rank as a good second in this country. (See diagram marked Exhibit B.)

Let us consider it settled, then, that certain arrangements of simple lines may be attractive or repellant if there be a proper basis for the design. The cross could be of no other shape and be effective. The dollar mark might possibly be, but its composition from the letters U. S., standing for "United States," stamps it as almost an inspiration.

To go one step forward in our argument, it must be admitted that in the decoration of two similar objects, say stoves, the same elements may be used with equal skill, but unequal taste, the one being noble and attractive, the other ridiculous and repellant. We will take the liberty of using a well-known stove company's trade-mark as an example of singularly felicitous adaptation of simple elements in the diagram marked Exhibit C. Now, we will show how the same elements can be used to produce the opposite effect, that is, to repel, in diagram marked Exhibit D.

So much by way of introduction, and now we will go along together in a popular view of some of the analogies of color and sound.

Those among us who have made a serious study of design and ornamentation know something of the difficulties in the way of making an explanation of the principles involved which will be so interesting as not to trespass upon the indulgence of the average listener; but I shall avoid technicalities and purely speculative propositions, so that every one here may easily follow the procession of the argument.

We have little to do with color in the decoration of stoves, yet it will be profitable to take enough time to state some of the primary analogies between color and sound, expressed for convenience, by the musical terms Tonic, Medient and Dominant (or the Keynote, third and fifth of the scale), as shown in Exhibit F. These in color would be the three primaries, red, yellow and blue, and to make this very plain and easily followed we will use a diagram showing these in the same position on a staff as if really musical notes. (Exhibit G.)

Now in music there are seven notes, four besides those mentioned—viz: The Supertonic, the Sub-dominant, the Sub-medient and the Sub-tonic, the eighth being of course the Octave tonic and therefore the commencement of a new series. But this presents no difficulties in the adaptation of the principle in color, for we have the proper notes for the four vacant spaces, viz.: Orange, green, purple and neutral gray, or, according to Sir John D. Macdonald, orange, green, indigo and violet. (Exhibit H.)

The inclusive octave of both sound and color is very simply shown on paper, and we think a harmonic unison established, so that all will intuitively recognize it. (Exhibit I.)

In Exhibit J (not illustrated) we may see an octave on the pianoforte keyboard with the corresponding tones of color properly located, and also the principal harmonies arranged in their natural sequences. This is according to the late G. G. Finn and is not precisely the same arrangement as we have used, but it is practically identical, the difference being in the reading of the prismatic wave length.

It must not be thought that because authorities differ in minor matters regarding the scale of color there can be any question about the scientific arrangement.

In regard to the difference above noticed, it can be very simply explained in this way: Blue and red mixed together mechanically produce an intermediate pure purple, but there are other ways to get at the intermediate besides actually mixing colors; in the prism, for instance, the diffusion of the yellow ray causes two colors to be shown—indigo and violet. If we had the time other apparent discrepancies could be explained on similar lines.

Sound and Color.

From the foregoing you will see that there is an analogy between the effects produced upon the hearing and the seeing organs of sense, but the similarity is still more striking when you consider that both are produced by vibrations more or less rapid, the one striking the retina of the eye, the other the drum of the ear, tones of color or sound being pitched in exact accord with the number of vibrations per unit of time, as has been scientifically demonstrated—*e. g.*, red, our tonic, is produced upon the retina of the eye by an atmospheric movement of 477,000,000,000,000 of vibrations per second, while the corresponding sound shown here as the middle C of our musical scale at concert pitch would be about 256 vibrations on the drum of the ear for the same time, and the ratio remains almost constant from tonic to octave and from red to violet.

Gentlemen, this to me is a most fascinating subject. You will get tired of it before I do, but I will hasten all I can. It is quite possible that the future musical symphony or etude may be written out, not on a staff as now, but in colors representing homologous musical tones. These can be tinted and merged into each other until the effects not now possible of expression in musical notation may be faithfully and felicitously shown by a scheme of color. This has only been impracticable heretofore because we have had no artificial light which would enable an untrained eye to distinguish between certain colors and shades, such as blue and green and indigo and violet. Now, however, with the electric light perfected to show all the various gradations of color, we may safely predict considerable activity in this field among scientific men in the near future. In Exhibit L I have caused to be written a grand old hymn in tones of color side by side with the accepted musical score, and, lacking some better illustration, I will attempt to show on my violin how the melody may be read and interpreted by means of the gradations and modulations as shown in the colored sketch. Notice the harmony of the tints and shadings to each other. Almost any good bit of musical harmony will work up with the same beauty and consistency in tones of color.
